16,148 (1921). Pearson, Craig, and Durelco, Ltd. Electrolytic treatment of metalliferous materials containing tungsten or molybdenum. (185,842.) Sep. 27.

16,489 (1921). Fairweather (Hybinette and Peek). Treatment of matte ond other materials and solutions containing copper and nickel. (185,859.) Sep. 27.

18,258 (1921). Dickins. Case hardening, hardening, tempering, etc. (185,564.) Sep. 20.

XI.—ELECTRO-CHEMISTRY.

Applications.

David and Dutt. Electric cells. 25,307. Sep. 19.

Gross. Accumulator electrodes. 25,282–3. Sep. 19. (Norway, 17.10.21.)

Teale and Whitehead. Electric accumulators. 24,776. Sep. 13.

Complete Specifications Accepted.

13,398 (1921). Garbutt. Electric accumulators. (185,797.) Sep. 27.

15,047 (1921). Thompson (Aikens). *See* X.

16,148 (1921). Pearson and others. *See* X.

23,066 (1921). Palmer and Ashton. Electric accumulators. (185,946.) Sep. 27.

XII.—FATS; OILS; WAXES.

Application.

Quick. Method of thickening oils. 25,429. Sep. 20.

Complete Specifications Accepted.

10,084 (1921). Plauson. *See* II.

10,692 (1921). Meyer zu Eissen and Kiederich. *See* II.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Applications.

Barry. Aluminium paint. 24,561. Sep. 11.

McDougall. Linoleum, floor coverings, etc. 25,623. Sep. 21.

Complete Specification Accepted.

19,340 (1921). British Thomson-Houston Co. (General Electric Co.). Coating materials and methods of forming same. (185,910.) Sep. 27.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Applications.

Bateman. Rubber solutions or cements. 25,229. Sep. 18.

Bigger and Falls. Rubber substitutes. 25,431. Sep. 20.

Schidrowitz. Manufacture of rubber. 24,950. Sep. 14.

XV.—LEATHER; BONE; HORN; GLUE.

Application.

Duckworth. Treatment of skins. 25,275. Sep. 19. (Australia, 28.9.21.)

Complete Specification Accepted.

19,841 (1921). Collard. Extraction of gelatin. (166,896.) Sep. 20.

XVI.—SOILS; FERTILISERS.

Application.

Asahi Glass Co., and Igawa. Application of colloidal magnesium silicate as a forcing agent of manure. 25,538. Sep. 21.

XVII.—SUGARS; STARCHES; GUMS.

Complete Specification Accepted.

9151 (1922). Jacobs (Jacobs). System of pan boiling in sugar manufacture. (185,707.) Sep. 20.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

Applications.

Board and Gills. Rubbing-plate for milk-drying machines. 25,474. Sep. 20.

Carpmael (Chem. Fabr. Weiler-ter Meer). Manufacture of insecticides. 24,939. Sep. 14.

Elrod. Sewage disposal plant. 24,672. Sep. 12.

Hartley and Hartley. Purification of sewage. 25,398. Sep. 20.

Hoare. Manufacture of milk products. 24,896. Sep. 14.

Sawada. Cleaning rice grain. 24,924. Sep. 14. (Japan, 27.9.21.)

Complete Specifications Accepted.

9776 (1921). Green. Purification of sewage by treatment in centrifugal separators. (185,444.) Sep. 20.

13,411 (1921). Pennell. *See* I.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Applications.

Calvert. Treatment of alcohols. 25,803. Sep. 23.

Goldschmidt and Neuss. Manufacture of condensation products. 25,489. Sep. 20.

Complete Specifications Accepted.

14,986 (1921). Meister, Lucius, u. Brüning. Manufacture of methylsulphites of secondary aromatic-aliphatic amines. (164,002.) Sep. 20.

19,536 (1921). Imray (Soc. Chem. Industry in Basle). Manufacture of amino-alcohols of the quinoline series. (185,913.) Sep. 27.

21,567 (1921). Meister, Lucius, u. Brüning. Manufacture of aliphatic dialkylaminoalkyl compounds. (167,781.) Sep. 20.

14,537 (1922). Meister, Lucius, u. Brüning. Manufacture of sulphonic acids of the 2.3-oxy-naphthoic acid arylides. (183,428.) Sep. 20.

I.—GENERAL; PLANT; MACHINERY.

Maximum temperatures [developed in chemical reactions, e.g., combustion] Rapid calculation of ——. G. G. Brown. Chem. and Met. Eng., 1922, **27**, 497—500.

The maximum temperature developed in a chemical reaction may be calculated by the graphical method, by trial, or algebraically. The last-named method depends upon the solution of a quadratic equation which may be conveniently solved either graphically or by use of the slide rule. The various methods are described.—J. S. G. T.

Colloids; Theory of the mechanical synthesis of ——. F. Sekera. Kolloid-Zeits., 1922, **31**, 137—147.

The theory of the production of colloids in Plauson's colloid mill is briefly as follows: The mechanical grinding process bursts the active molecular compounds in the interior of the solid substance and produces particles of colloidal dimensions. The residual valencies, active at the surface of these particles, tend to cause an aggregation of the particles, so that secondary to the dispersion an aggregation process will take place. To retard or prevent the aggregation the residual valencies are saturated by the addition of an electrolyte, whereby salt complexes are produced and the particles become electrically charged.—J. F. S.

Colloids; "Fog process" for the preparation of ——. F. Sekera. Kolloid-Zeits., 1922, **31**, 148—149.

A manufacturing process by which solid colloids may be prepared is described. The principle of the process is best explained by an example: to a 30% solution of sulphur in carbon bisulphide 5% of a high molecular organic salt is added, in this case sulphonated naphthenic acid, and the mixture placed in a heating chamber at 85° C. The solution is then dispersed by a stream of nitrogen, and a fog produced; the carbon bisulphide is condensed and runs away, whilst the colloidal particles are left suspended as a fog. The fog is condensed on two wire nets covered with parchment which spread right across the chamber and from which point electric discharges are passing. The colloid, which settles as a light powder, is soluble in water.

—J. F. S.

Patents.

Transfer of heat between liquids and gases; Apparatus for effecting ——. Atkiebolaget Ljungströms Angturbin. E.P. 162,250, 21.4.21. Conv., 23.4.20.

A cylindrical tube is divided by a diametral plane into two equal flues of semicircular cross-section. The hot gases flow in one direction through one of these flues, and the gases to be heated flow, usually in the opposite direction, through the other flue. At a suitable position in the tube the internal partition is removed, and in the space thus provided is mounted a rotating disc together with its driving gear. This disc may be made up of a series of radial plates. In the larger units the disc is built up of a series of concentric rings, each ring being attached to the next by a series of short radial plates. The chambers thus formed in the disc may be packed with materials, such as gravel, slag, tiles, etc. This disc is caused to rotate across the line of flow of the hot gases in the one flue and the gases to be heated in the other and transfer heat from one flue to the other.—S. G. U.

Selective corrosion; Prevention of —— in machines or apparatus of metallic parts made of copper and copper-containing alloys, and subject to the corrosive action of water containing ions. F. von Wurstemberger. E.P. 174,059, 29.12.21. Conv., 17.1.21.

The water is prevented from becoming stagnant anywhere in contact with the vessel, *e.g.*, by means of a special circulating pump; in the case of a heat exchanger, the pump may have a much reduced delivery when the apparatus is out of use.

—B. M. V.

Refrigerating apparatus. J. G. Deremer. E.P. 182,528, 24.3.21.

Two cylinders, one the compressor, the other the evaporator, are connected together by a tube so that their axes lie on a straight line. The compressor is fitted with a hollow plug which forms a low-pressure chamber at the evaporator end and a high-pressure chamber at the other end of the compressor cylinder. These chambers are connected by a helical passage, cut on the outer surface of the plug, and of gradually diminishing cross-section. The compressor casing forms the outer wall of this passage. Fixed to the low-pressure end and passing through the plug is a pipe which extends into a recess formed in the outer cover of the compressor cylinder. In the annulus formed by this pipe and the plug is fitted a second helix having its pitch in the same direction as the outer. As this helix does not reach the end of the plug a second high-pressure chamber is formed which is connected to a cooling coil surrounding the compressor cylinder. The compressed refrigerant fluid after passing through this coil enters a pipe placed inside the connecting tube and is discharged into a sealed tube forming an extension of the connecting tube inside the evaporator. The discharge from this sealed tube enters an annular chamber placed inside and in direct communication with the evaporating chamber. From this chamber the fluid passes through a coil surrounding the evaporator and is then returned to the sealed tube. On again entering the evaporating chamber the liquid portion is circulated through the surrounding coils, whilst the gaseous portion enters the connecting tube and is returned to the compressor. To deal with the accumulation of excessive amounts of propelling liquid in the evaporator when the machine is at rest, an arrangement is provided for returning this liquid direct to the compressor cylinder when the plant is started. The unit comprising the evaporator and compressor is supported at its ends, so as to be inclined at about an angle of 45° to the driving shaft by which the unit as a whole is rotated. In addition bevel gearing is employed to give the unit rotational motion about its own axis. The compressor cylinder rotates in a chamber provided with a spray which plays upon the coils and cylinder. The evaporator rotates in another insulated chamber provided with a circulating device which brings the liquid to be cooled into contact with the coils on the evaporating cylinder. Mercury and sulphur dioxide are recommended as the propelling and refrigerant fluids respectively.

—S. G. U.

Steam; Generation and superheating of ——. F. Lamplough. E.P. 183,261, 21.4.21.

Exhaust steam is led through the annulus formed by two coaxial pipes, whilst live steam passes through the inner pipe. The outer pipe is heated by furnace gases, thus superheating the exhaust steam which in turn conveys heat to the live steam. After passing through this heater the exhaust steam enters a chamber fitted with a series of coils, one end of which is coupled to the inlet end of the live steam pipe already mentioned and the other end to the outlet pipe from the feed water heater. In this chamber the live steam is generated. The exhaust steam next passes through a feed water heater and ultimately through a condenser. A pump forces the condensed water and feed water into a receiver which is in direct communication with the live steam side of the plant. This receiver also communicates with a cylinder containing two spring-loaded pistons operated by the pressure in the receiver. One of these pistons actuates a mechanism for altering the stroke of the feed pump, shortening the stroke as the pressure rises, and the other operates a valve whereby the pump delivery can be by-passed and returned direct to the condenser.—S. G. U.

Grinding, refining, and mixing machines. J. McIntyre. E.P. 183,399, 10.12.21.

A cylinder jacketed to take either hot or cold water or steam is placed with its axis horizontal; its ends are fitted with covers, one of which is provided with a suitable opening for introduction of the material to be treated and the other with a long stuffing-box and gland which also acts as the bearing for the main shaft of the machine. This shaft is hollow and is driven at the outer end through worm and screw gearing.· At the inner end it is keyed to a wheel which carries round its circumference a series of rockers, which can swing through a limited arc. A flexible blade, as described in E.P. 181,877, is attached to each complete rocking unit. Round the rim of the wheel is a slip ring, provided with slots which engage with these blades in such a way that any movement given to one blade is immediately communicated to all the others. Through the hollow shaft passes a spindle carrying bevel gear at its outer end and rigidly fixed to a disc crank at its inner end. The pin of this crank is connected through a link with one of the rocking levers. The bevel gear at the outer end is so mounted that it rotates with the main shaft, but by the insertion of a pin in one or other of two holes provided in the casing can be given a motion relative to the main shaft, thereby altering the pressure between the blades and the casing. The outlet valve of the machine is of the piston type, so arranged that when closed the top of the valve is flush with the inside of the cylinder and on lowering the piston its inner edge uncovers a port permitting the finished material to flow out.—S. G. U.

Disintegrating minerals and similar materials; Machines for reducing or ——. A. G. N. Burden. E.P. 184,609, 28.5.21.

In a rotary disintegrator, in order to reduce wear on the impellers, the material is fed as nearly as possible to the centre of the runner, which is shaped so as not to be subject to the impact of the material, *e.g.*, it may take the form of a disc with guide vanes so designed that there is no relative peripheral motion between the material and the runner, centrifugal force alone being relied on to provide the impact with the stationary outer ring or anvil, which is serrated so that its working faces are approximately perpendicular to the flying particles. After impact the crushed material is not allowed to become entagled with the runner again, but it is allowed to fall clear, and if desired may be re-ground in a similar apparatus. [Reference is directed, in pursuance Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 444 of 1876, 533 of 1882, 5837 of 1884, 3654 of 1901, 25,880 of 1903, 17,990 of 1908, 29,717 of 1910, and 160,933.]—B. M. V.

Pulverising mill. D. V. Sherban. U.S.P. 1,427,234, 29 8.22. Appl., 23.12.21.

A ball mill is provided with an axial suction duct or screen extending right through the mill for withdrawing ground material.—B. M. V.

Dry-pulverising apparatus. R. E. H. Pomeroy. U.S.P. 1,427,322, 29.8.22. Appl., 30.6.20.

A rotating casing is provided with inlets for air on its periphery. Other apertures are provided for the entry of unground material and for the discharge of the air current carrying the ground material.—B. M. V.

Cooling towers; [Distributing troughs for] water ——. C. M. Bennett, and Film Cooling Towers, Ltd. E.P. 184,653, 2.7.21.

In the ordinary distributing troughs at the top of cooling towers, provided with short vertical pieces of pipe to deliver the water, the upper ends of the pipes are subject to partial obstruction by vortices. To avoid this the upper ends of the pipes are provided with return bends lying within the troughs, converting them into siphons, and causing a more rapid and more uniform discharge of the water. —B. M. V.

Furnaces; Regenerative ——. H. Wade. From The Union Trust Co. E.P. 184,877, 20.5.21.

At each end of a reverberatory furnace are three ports, all of which communicate *viâ* downtakes with the usual regenerator chambers. The downtakes from the outer (auxiliary) ports are provided with dampers or valves, but the central ports and downtakes are not so provided. At the outlet end of the furnace all the ports are used to carry away the products of combustion, but at the inlet end the auxiliary ports are closed and the fuel (gas, oil, or powdered coal) is supplied to the central port where it mixes with the heated air, so that the flame enters only by the central port, which is not enlarged beyond the point of entry of the fuel. —B. M. V.

Furnaces, stoves or the like; Method of and means for raising and maintaining the temperature in ——. I. E. Robinson. E.P. 185,217, 31.5.21.

The greater part of the products of combustion containing partially consumed fuel is returned to the combustion space or fireplace of a furnace, and while circulating is expanded and contracted one or more times. The expansion and contraction may also be applied to that portion (the waste gases) that passes to the exit flue. A self-contained boiler is described which generates superheated steam for effecting the circulation.—B. M. V.

Evaporators or heaters, heated by waste hot gases; Water or other liquid ——. H. Hocking. E.P. 185,134, 18.2.21.

The liquid to be heated is contained in a casing, into which projects a nest of outer fire-tubes or "radiators" with one end closed, which are secured at their open ends in a tube-plate. The tube-plate has a hollow cover provided with inlet and outlet ports for hot gases, also with a diagonal partition or tube-plate carrying smaller inner tubes open at both ends which are inserted into the outer fire-tubes and form the only passage for the hot gases between the inlet and outlet ports. —B. M. V.

Electrical precipitation; Apparatus for ——. C. Le G. Fortescue, Assr. to Westinghouse Electric and Mfg. Co. U.S.P. 1,427,370, 29.8.22. Appl., 15.2.19.

A porous ionising electrode is disposed within a treatment chamber in which baffles are arranged, so that the stream of fluid to be treated is subjected, during its passage through the chamber, several times to the ionising action of the electrode. —J. S. G. T.

Electrode for precipitating apparatus; Ionising ——. C. Le G. Fortescue, Assr. to Westinghouse Electric and Mfg. Co. U.S.P. 1,428,839, 12.9.22. Appl., 25.2.19.

In an electrical precipitation system, a collecting electrode is formed as a treating chamber, and the reticulated discharge electrode employed may be charged to different potentials substantially simultaneously.—J. S. G. T.

Electrical gas-cleansing apparatus. Metallbank u. Metallurgische Ges. A.-G. G.P. 354,623, 27.7.20.

Discharge electrodes are carried by conducting laminæ disposed in the conduit for supplying gas to the plant and supported by transverse insulated bars.—J. S. G. T.

Catalysing apparatus. J. McC. Selden, Assr. to The Selden Co. U.S.P. 1,427,554, 29.8.22. Appl., 22.3.18.

The catalyst is contained in a number of troughs arranged in staggered relation, one above the other, within a casing, a conduit for a heating or cooling fluid being buried in the catalyst in each trough. The reacting gases are admitted to the lower, and removed from the upper, part of the casing.

IIA.—FUEL; GAS; MINERAL OILS AND WAXES.

Coal from the deeper workings of the Kenadza (Algeria) mine; Composition and calorific power of ——. A. Foix. Bull. Soc. Chim., 1922, **31**, 813—816.

The samples examined were found to contain about 7% of ash, 3% of sulphur, and 2·5% of nitrogen, the corresponding values for coal from the surface workings being 3%, 1%, and 0·5% respectively. A detailed analysis of the ash is given, from which it is inferred that the whole of the sulphur is in the form of iron pyrites. This accounts for all the iron present, whereas the iron in the surface coal exists chiefly as ferric oxide. Determinations of the calorific value do not agree so closely with the value calculated from Goutal's formula as those given by the surface coal. The heat evolved on combustion varies from 8240 to 8270 g.-cals. per g., being 3—4% above the calculated value.
—H. J. E.

Coals; Comparison between the American and S. African methods for the determination of volatile combustible matter in ——. J. A. McLachlan. J. S. Afr. Chem. Inst., 1922, **5**, 6—11.

In the S. African method 1 g. of the sample is heated in a covered platinum crucible over a gradually increasing Bunsen flame until the sample ceases to give a flame at the lid, and the heating is then continued for exactly 30 secs. The American method consists in heating 1 g. of the sample in a covered platinum crucible over a full Bunsen flame for 7 mins., the size of the crucible, its height above the flame, and the size of the latter being definitely prescribed. At present it would seem that neither method yields concordant results. Only one detail as regards the heating is specified in the S. African method, a fact which allows a wide variation in the results; the fuller specification in the case of the American method enables consistent results to be obtained when the determinations are made over one and the same burner, but different burners, having the same length of flame, have different heating values, and in this respect the method is defective.—W. P. S.

Coal; Cleaning ——, *specially for the production of coke low in ash.* A. Thau. Stahl u. Eisen, 1922, **42**, 1153—1158, 1242—1249.

The flotation process is a valuable addition to the mechanical methods of removing the ash components of coal. In some cases the ash content may be reduced 70%. There is also a considerable reduction of the sulphur content, which is chiefly carried by the finest ash and coal particles. The treated slime from the flotation process gave excellent coke, and when added to coking coal had a favourable influence on the character of the coke both from a chemical and physical point of view. Coal treated by the flotation process can be brought to so high a degree of purity that it is better suited for chemical use and for the manufacture of electrodes than the raw materials previously used. The waste from the flotation process may be used, according to its chemical constitution, as raw material for ceramic products. Calculations are made showing the economic advantages of the flotation process and of the purified coke produced.—T. H. Bu.

Coal; Spontaneous ignition of ——. T. Drescher. Chem.-Zeit., 1922, **46**, 802—803.

The paint industry employs as a black pigment what is essentially coke (lignite-coke, bone-charcoal, etc.) sold under various trade names. The grinding of this material often extends over 24 hrs. and is carried out in edge-runner mills or closed drums, the powder being discharged warm, but notwithstanding this no case of spontaneous ignition is known. When, however, an attempt was made to use coal as a substitute, the coal being of good quality but containing pyrites, the powder took fire while in store. The material was therefore stored in bags in the open, the ground being frozen. When after 14 days the upper bags were removed the lower ones with a good part of their contents were found to have been burnt. The material was repacked in fresh bags and in a few days took fire again. This case is held to support the view that such fires are due to the oxidation of pyrites by air and moisture. There will always be sufficient air between the particles of a dump of small coal to start the action.—C. I.

Coke; Dry cooling of ——. P. Schläpfer. Stahl u. Eisen, 1922, 42, 1269—1275.

The mean specific heat of a coke containing 10·5% of ash was found to be as follows for various temperature intervals: 18°—100°, 0·214; 18°—400°, 0·273; 18°—477°, 0·286; 18°—577°, 0·305; 18°—800° C., 0·333. In a dry cooling installation described, the coke is discharged from the oven into an enclosed chamber, and air is admitted. A small portion of the coke is thus burnt, until all the oxygen of the air admitted has been utilised, after which the inert gases, consisting of nitrogen, carbon dioxide, and carbon monoxide, are circulated through the cooling chambers until the temperature of the coke has fallen to about 250° C. The sensible heat of the circulating gas is utilised for generating steam or for preheating boiler feed water. The speed of circulation can be regulated to suit the steam requirements of the plant. In one test, lasting 17 days, the weight of coke cooled per day was 23·6 tons, and the water heated amounted to 9·4 tons, converted from water at 50° C. into steam at 94·5 lb. per sq. in. pressure (saturated), *i.e.*, 0·398 kg. of steam per kg. of coke. Over a test period of 285 days, the steam generated amounted to 0·383 kg. per kg. of coke. A complete description is given of the lay-out of the plant.
—A. G.

Coke; Volumetric determination of the true and apparent specific gravity of ——. A. Schmolke. Stahl u. Eisen, 1922, 42, 1237—1240.

A weighed piece of dry coke is introduced into a volumenometer, the volume of which has previously been determined by displacing the contained air by means of carbon dioxide into an absorption vessel containing a solution of caustic potash and reading off the volume of the air in a graduated glass tube. The volume of air in the glass vessel when containing the coke is determined by a similar procedure, the carbon dioxide displacing the air in the pores of the coke. The weight of the coke divided by the difference between the volume of the vessel and the volume of air in the vessel when containing the coke gives the true density of the coke. The experiment is then repeated, using mercury instead of carbon dioxide; the mercury does not displace the air in the pores of the coke, and consequently the apparent density of the coke is obtained. The method is rapid and accurate.—T. H. Bu.

Calorific power; Calculation of the —— *of a commercial fuel in terms of its content of water and mineral matter.* J. Fohlen. Chim. et Ind., 1922, 8, 275—277.

The application of nomographs to the determination of calorific powers of fuels of known content of water and mineral matter is explained and illustrated in the cases of four varieties of coals, for which rectilinear nomographs are given.
—J. S. G. T.

Metaldehyde as a fuel. H. Danneel. Chem. and Met. Eng., 1922, 27, 216—218.

The manufacture of metaldehyde on a commercial scale has become possible through the production of acetaldehyde from calcium carbide. A study of the acetaldehyde-metaldehyde-paraldehyde equilibria shows that at low temperatures the conversion of acetaldehyde into metaldehyde can be accelerated more than that of acetaldehyde into paraldehyde by the use of sulphuric acid or certain other catalysts. As the formation of paraldehyde is accompanied by the evolution of heat, careful control of the reaction temperature is necessary. The precipitated metaldehyde is removed when a maximum quantity has been formed and before equilibrium is reached. Paraldehyde, with small quantities of acetaldehyde, is separated in a hydro-extractor and, unless pure paraldehyde is desired as a product, is transformed into acetaldehyde for further use. Metaldehyde is recovered in the form of small needles and is compressed before being used as a fuel. During combustion the heat radiated from the flame converts the metaldehyde into acetaldehyde, which itself feeds the flame; thus the conversion controls the rate of combustion. The formation of acetaldehyde and the combustible properties of the compressed metaldehyde are very largely determined by the presence of traces of catalysts.—H. Hg.

Hydrocarbons; Determination of —— *in technical gases.* G. Wollers. Stahl u. Eisen, 1922, 42, 1449—1455.

Gases of the acetylene series may be separated quantitatively from those of the ethylene and methane series by shaking with a few c.c. of a solution of 25 g. of mercuric iodide and 30 g. of potassium iodide in 100 c.c. of water. Ethylene and its homologues may be separated from the residual gases by shaking them with a solution of 1 g. of vanadic acid in 100 c.c. of concentrated sulphuric acid, but it is impossible to effect a separation of the ethylene homologues from each other by agitation with sulphuric acid of different strengths. All the unsaturated hydrocarbons on being passed over palladium black saturated with hydrogen are converted quantitatively into the corresponding saturated compounds. The various members of the different series may be separated by cooling the gas mixture in liquid air to −185° C., whereby oxygen, hydrogen, carbon monoxide, methane, and nitrogen remain in the gaseous state and are determined in the usual manner. The liquid is heated to −115° C., when ethylene, ethane, and part of the propylene and propane distil off, and then to room temperature, when the rest of the propylene and propane, together with a little butylene and butane distil. Each fraction is analysed by the absorption method described above combined with combustion of another portion.—A. R. P.

Hydrogen and methane mixed with atmospheric air; Fractional combustion of ——. P. Rischbieth. Chem.-Zeit., 1922, 46, 784—785.

The combustion is carried out in a pipette, or flask, in which is a spiral of platinum wire which may be raised to any desired temperature by an electric current. The pipette is connected by a pipe provided with a glass cock with a graduated burette fitted with a levelling bottle. For the combustion of hydrogen the wire is heated to a temperature below redness. Methane is only burned by raising the wire to a bright red or white heat. The combustion takes place without explosion. After combustion the gas is withdrawn into the burette and the contraction in volume estimated. If desired the amount of methane may be found by estimating the residual oxygen by a phosphorus pipette and thus ascertaining the volume of oxygen used.—H. M.

Natural gas; Composition of Japanese ——. T. Ohno. Kôgyô-Kwagaku Zasshi (J. Chem. Ind. Japan), 1922, 25, 783—788.

Samples of natural gas from Haneda-machi (Tokyo Prefecture), Mohara-machi and Tsuchimutsumura (Chiba Prefecture), Niitsu oil-field, and Nuttari petroleum refinery gave the following results on analysis: CO_2 1·2—14·9, C_nH_{2n} 0—0·1, O_2 0·2—0·7, CO 0—0·2, CH_4 79·1—92·1, N_2 4·6—11·3%; sp. gr. 0·577—0·725, calorific value 7023—8444 g.-cals. per litre. A sample from Nishiyama oil-field (Niigata Prefecture) proved to be a natural petroleum gas and gave the following results: CO_2 0·2—0·5, C_nH_{2n} 0·7—1·0, O_2 0·5—0·6, CO 0·4, CH_4 22·8—44·0, C_2H_6 54·2—71·3% (saturated hydrocarbons were calculated as CH_4 and C_2H_6), sp. gr. 0·807—0·963, calorific value 13,090—13,293 g.-cals. per litre. —K. K.

Kukkersite, the oil shale of Esthonia. E. H. C. Craig. J. Inst. Petrol. Tech., 1922, 8, 349—375.

The Esthonian oil shale is the oldest and richest known, if torbanites be excluded. The oil shale is found a few yards above the base of the lower silurian limestone, attains a maximum thickness of 8 ft., and is interbedded with limestone containing bituminous matter. The strata have never been disturbed since their formation. The shale is grey to green, but red when weathered, and is crowded with fossils, principally trilobites and brachiopods. The sp. gr. varies from [illegible]2 to 1·4, and the yellow colour of the impregnation is similar to that of the richest shales of Colorado. The material contains no sand. Analysis of the mineral (inorganic) matter shows 49·64% of lime. The moisture varies from 33·7 to 11·0%, but after six weeks' drying at ordinary temperature this is reduced to 6·84—2·34%. The average percentage of volatile matter is 54—56. The nitrogen content is low, 0·30—0·68%, and the oxygen content high, 16·24—21·98%; the sulphur content is 1·60%. Kukkersite may be distilled at a temperature not above 500° C. and yields 70—80 galls. per ton of an oil of 0·92—0·93 sp. gr. It is not likely that the shale originated from algæ or from peat, but it is most probable that it has been formed from inspissated petroleum, the underlying Cambrian sandstone presenting the typical appearance of oil sands. The quantity of proved oil shale is about 1000 to 1500 million tons, extending over an area 36 miles long by 7 miles broad. Along the outcrop and for some miles to southward the shale may be worked by open cut.—H. M.

Kukkersite; Chemical composition of the Esthonian Middle Ordovician oil-bearing mineral ——. P. N. Kogerman. Pamphlet. Dorpat, 1922. 25 pages.

The available supply of Esthonian oil shale is estimated at 1,500,000,000 tons. It is not a true shale. A review is given of former researches on kukkersite from its discovery in 1789 to the present day. The shale rarely contains more than 35% of moisture. When air-dried it contains about 7% of moisture and when dried in a desiccator over sulphuric acid about 2·38%. The ash content varies from 20 to 50%, and the yield of volatile matter is 50·7—58·4%. The ultimate composition of the dry organic substance is C 71·58%, H 7·40%, N 0·48%, S 1·50%, O 19·04%. From 0·27 to 0·77% of the mineral was dissolved by eight different organic solvents, but tetrachloroethane dissolved 2·20%, the time of extraction varying from 48 to 124 hours. By boiling in a 20% solution of potassium hydroxide, neutralising, and allowing to stand, a white precipitate not exceeding 4% of the weight of the mineral was obtained. In one series of tests 10 g. of shale heated to 250°—255° C. gave off 27 c.c. of gas containing 8·7% of carbon dioxide, 0·6% of heavy hydrocarbons, and 13·7% of carbon monoxide. Distillation at 600° C. gave 74·8 galls. of oil and 3000 cub. ft. of gas per ton. By steam distillation 28·5% of light oil of sp. gr. 0·795 was obtained, containing about 60% of unsaturated open-chain compounds. Heavy oil obtained by steam distillation contained 77% of such compounds. The kukkersite is formed from a soft cyanophycean alga. Under the action of chloral hydrate the algæ swell and assume their original form.—H. M.

Petroleum; Origin of ——. [*Nitrogen compounds of petroleum, and particularly of Baku petroleum.*) E. Pyhälä. Petroleum, 1922, 18, 1069—1073.

Acid sludge from the refining of kerosene from Baku petroleum was diluted with water, when a violet oil separated, leaving a yellow acid solution, which gave a flocculent precipitate on the addition of an excess of alkali. The precipitate, washed and dissolved in hydrochloric acid, was brown, but turned carmine-red in a few hours. A thick red oil separated on the addition of common salt. This was dissolved in chloroform and the solvent then distilled off. On distilling this oil a pale yellow oil passed over between 60° and 80° C., and afterwards some water, sulphur dioxide, and turbid oil with odour of pyridine. Between 250° and 270° C. the greater part of the material distilled over as a substance similar to Canada balsam. This was dissolved in water, filtered, and evaporated at 80° C. A hygroscopic brittle mass was obtained, smelling and tasting like quinoline, with acid value 261 and possessing both acid and basic qualities; it is probably an amino-acid. In the distillation of the kerosene fractions of many kinds of petroleum a red to violet fugitive coloration is observed, and this is in proportion to the nitrogen content of the petroleum. The filtration of a petroleum from Surachany through floridine left a red coloured oil in the filtering medium. The yellow filtrate was shaken with sulphuric acid and the precipitated acid sludge diluted with water, rendered alkaline with sodium hydroxide solution, and shaken with ether. The ether layer was yellow, but on distilling off the solvent a syrupy carmine-red product remained, with a smell of quinoline and containing bases. The bases seemed to consist of the hydrogenised derivatives of pyridine and quinoline, and probably have been taken up by the petroleum from decomposed organic matter.—H. M.

Absorption plant [for recovery of gasoline from natural gas]; Design and operation of a low-pressure ——. W. P. Dykema and A. A. Chenoweth. U.S. Bureau of Mines, Tech. Paper 263, 1922. 40 pages.

The plant described deals with 2,000,000 cub. ft. of gas daily, and the yield of gasoline has ranged from 0·52 gall. per 1000 cub. ft. when the plant first started (May, 1917) to 8·45 galls. in Dec., 1919. A vacuum of 19—20 in. of mercury is maintained on the wells, with the result of a much increased production. A pressure of 4—6 lb. is maintained on the two absorption towers, which work in series. The gas is cooled by passing through pipes sprayed with water before going to the towers, which are filled with wood strips, to effect the distribution of the oil. The velocity of flow of gas in the towers varies in different parts from 7·5 ft. to 15 ft. per minute. The oil circulation is 100 galls. per minute. The gas, after passing through the towers, has a gasoline content of only 0·055 gall. per 1000 cub. ft. Its heat value is 1900—2000 B.Th.U. The results of fractionations of the gasoline from different points in the system are given. The absorbing oil is a gas oil of 35°—37° B. (sp. gr. 0·838—0·848). Graphs showing the heat exchange are given, as also drawings illustrating details of the plant, and tables showing results of working.—H. M.

Petroleum products; Temperature-pressure curves of ——. M. B. Cooke. Chem. and Met. Eng., 1922, **27**, 504.

Curves showing the relation of vapour pressure to temperature are given for casinghead gasoline, motor gasoline, kerosene, and a transformer oil, for temperatures ranging from 20° C. to 260° C. The respective distillation ranges are likewise shown graphically. In general, the pressures generated by petroleum products at high temperatures vary inversely as the average boiling point of the product.—J. S. G. T.

Paraffin wax; Composition of ——. F. Francis, C. M. Watkins, and R. W. Wallington. Chem. Soc. Trans., 1922, **121**, 1529—1535.

A paraffin wax of Scottish origin, melting at 55°—56° C., and showing a mol. wt. of 366, and sp. gr. 0·7628 at 85°/4° C., was subjected to twenty-one successive fractionations under a Young column at a pressure of about 0·1 mm. After seventeen fractionations large amounts of material were obtained boiling over small ranges of temperature, and the total boiling range had spread out from 170°—230° C. to 125°—280° C., though the amount boiling above 240° C. probably did not amount to more than 2—3%. Making allowance for the unavoidable loss during the distillations, it is considered that about 80% of the paraffin is composed of seven substances of constant boiling point. Of the remainder 8—10% is composed of material boiling at 220°—240° C. and containing probably not more than two such substances. It is as yet undetermined whether these constant-boiling substances are pure hydrocarbons, or mixtures of hydrocarbons. The physical properties, m.pts., densities, solubilities, etc., of the constant-boiling substances show a perfect regularity with increasing b.p., with the sole exception of the fraction boiling at 217°—219° C., but there is no evidence that they are normal paraffins as assumed by Krafft (J., 1908, 68); in fact the physical constants of synthetic dotriacontane do not fit into the series, although its mol. wt. is the same as that of the fraction boiling at 196°—198° C.—G. F. M.

Paraffin wax and vaseline; Examination of ——. E. Pyhälä. Petroleum, 1922, **18**, 1164—1165.

The sp. gr. is determined by the flotation of wax or vaseline in an alcohol-water solution. The substance in a melted state is dropped from a glass rod into warm alcohol, when it may be observed whether any air bubbles are present. The drops free from air are transferred to a measuring cylinder, and water is added till the aqueous alcohol is of the same sp. gr. as the drops, which then neither rise nor fall in the liquid. The gravity of the aqueous alcohol is then determined by ordinary methods. The importance of ensuring the absence of air bubbles in the determination of the drop point by Ubbelohde's apparatus (J., 1905, 941) is emphasised. The effect of different methods of filling the glass vessel is noted. A variation of about 3° in the results may be brought about by incorrect methods of filling.—H. M.

Boring and cooling oils (soluble oils); Examination of ——. T. Kaleta. Chem.-Zeit., 1922, **46**, 783—784.

For the estimation of soap, mineral oil, and fatty oil, 3—5 g. of the sample is mixed with 100 c.c. of cold water and treated with solution of calcium chloride. The precipitated calcium soap is washed with water and acetone, dissolved in hot benzol-alcohol mixture, and boiled with dilute hydrochloric acid. After cooling the mixture is extracted with ether and washed with water. To the solution is added 50 c.c. of neutral alcohol, and it is titrated with *N*/2 alcoholic potash solution, evaporated, dried, and the resulting soap weighed. The filtrate from the calcium soap is diluted with 100 c.c. of water and shaken with ether. The extract, containing the mineral and the fatty oil, is washed with water, and the ether evaporated off. The fatty oil is saponified by boiling with 50 c.c. of alcoholic potash solution, the alcohol is evaporated, and 100 c.c. of water added. The mixture is warmed and the fatty oil precipitated as calcium soap, which is filtered off and the fatty oil determined as potash soap. The mineral oil, which remains, is extracted by ether, washed, and filtered. The ether is distilled off and the mineral oil weighed. Alternatively, the saponification value of the mixed mineral and fatty oil may be determined, a correction made for free alkali in the soluble oil, the amount of fatty oil determined, and the mineral oil calculated by difference. The molecular weight of the fatty acids may be calculated by the formula: mol. wt. = (g. fatty acids × 56)/g. KOH used.—H. M.

Butadiene from ethylene. Zanetti and others. *See* XX.

Patents.

Peat; Treatment of ——. T. Rigby. E.P. 182,149, 3.1.21.

Peat is dehydrated in stages which comprise, first, mechanical removal of the bulk of water (after, if necessary, hydraulic transportation in cases where the water content of the original peat will permit), and, secondly, evaporative drying of the pulpy product in a film dryer operating in multiple effect (E.P. 181,035; J., 1922, 574 A) or on the vapour compression principle (E.P. 149,055, 150,068, and 150,807; J., 1920, 682 A, 712 A).—A. R. M.

Peat and the like; Drying of ——. T. Rigby. E.P. 182,157, 25.2.21.

The material to be dried is carried in a comparatively finely divided state in suspension in a current of hot gaseous products of combustion along a duct. The carrying current is, for the most part, composed of gaseous products which have already once passed along the duct whilst functioning as a drying medium, only a portion of the cooled current being exhausted, the remainder, after the addition of fresh hot gases, being re-circulated. The material when sufficiently dried is separated from the current by a cyclone separator. The pressure at the point or points where fresh drying gases are introduced into the system and where the material to be dried is admitted, is kept below that of the atmosphere.—A. R. M.

Peat; Process and means for dehydrating raw ——. C. Glinka. G.P. 355,865, 24.7.21.

Raw peat is continuously conveyed through a chamber in which it is subjected at a suitable temperature to high pressure by means of rollers.
—A. J. H.

Coal briquettes; Production of ——. W. W. Stenning, W. H. Beasley, and Minerals Separation, Ltd. E.P. 185,216, 31.5.21.

A mixture of crushed coal and about its own weight of water, such as is produced by the froth-flotation process, is mixed with a binding agent such as pitch. The pitch is preferably added in a powdered or molten condition, while the mixture is being agitated and aerated. Naphthalene or coal tar may be added to facilitate the subsequent dissemination of the pitch. The mixture is heated to about 80° C. and submitted to a rolling form of agitation in a horizontal rotary drum, so that air is eliminated and the coal is agglomerated. Rods may be placed in the drum to knead the mass. Water is drained away from the agglomerated coal, which is briquetted while still hot.—H. Hg.

Oven for semi-coking of fuels. H. Lentz. E.P. 166,544, 15.7.21. Conv., 15.7.20.

Fuel is passed downwards over a series of inclined surfaces arranged in stepped formation over heating flues. The passage of fuel on to each step is controlled by a flap which is operated through the end wall of the oven in such a manner that the fuel is turned over during its passage. The flaps may be operated by a common drive. The gases evolved from the fuel are withdrawn through the top of the oven. The coked fuel passes from the lowest step through crusher rollers into trucks. The gas from the heating flues is passed through the fuel in a chamber above the upper end of the oven and serves to prevent access of air to the oven during the operation of the top flap. Several ovens may be arranged in series, the first being used for a preliminary drying of the fuel.—H. Hg.

Coke-oven. E. Artzinger. G.P. 354,153, 1.2.21.

In a vertical coke-oven with vertical heating flues, a recuperator with vertical flues is provided on either side of the oven for preheating the gaseous fuel and air, which pass through the flues from top to bottom in parallel. The recuperators are so placed that the temperature of either wall of the oven can be regulated independently of the other and so that the general design of the oven is as simple and as sound as possible with regard to thermal expansion.—H. C. R.

Drying and carbonising fuel; Apparatus for ——. A. Holzhausen. G.P. 355,386, 6.2.21.

Two cylinders, one inside the other and both revolving on the same axis, are connected by means of an interceptor, through which the fuel is transferred by means of gravity or other suitable means from the inner to the outer cylinder, but the passage of vapours or gases from one cylinder to the other is prevented. The transferring device is so operated that the fuel may be loosened, compressed, or briquetted whilst being conveyed from one cylinder to the other.—A. J. H.

Gas generators and/or retorts. F. Umpleby and H. Powers. E.P. 184,887, 23.5.21.

Solid or liquid fuel is gasified by being passed downwards into a cylinder composed of porous refractory material or of a perforated heat-resisting metal which is heated by surface combustion. Gas and air for combustion are supplied to an annular space surrounding the cylinder at a pressure exceeding that within the cylinder. This annulus, together with the upper and lower parts of the generator, is surrounded by a water jacket. Metallic flanges are provided to conduct heat from the outer surface of the cylinder to the water jacket. Solid fuel is introduced in powdered form through a rotary valve, or liquid fuel through a jet, at the top of the generator, or fuel may be injected by means of air or of steam generated in the cooling jacket. Lime or chalk may be introduced with the fuel. Baffles may be provided within the cylinder to impede the flow of the fuel and may be composed of catalytic material. Surplus water from the cooling jacket may flow into a tank at the base of the generator, and ash may be discharged into this through a rotary valve. The steam generated, if not used for the injection of fuel, is introduced into the top of the cylinder. The gases resulting from the interaction of fuel, steam, air, and products of combustion are withdrawn from the bottom of the cylinder under pressure or suction and may be supplied to internal-combustion engines. —H. Hg.

Coal, hydrocarbons, and the like; Process for decomposing —— under high temperatures and pressures. S. Löffler. G.P. 306,356, 24.1.15.

The temperature of the reaction chamber is controlled and the pressure on the walls of the chamber counterbalanced by means of a fluid (*e.g.*, oil) bath under pressure, stable under the necessary high temperatures employed. The pressure on the fluid bath may be slightly greater than that in the reaction chamber, and it is advantageous to use for the fluid bath hydrocarbons of high b.p. similar to those employed in the reaction chamber, so that in the event of the walls of the latter becoming damaged, harmful contamination of the reaction mixture does not occur.—A. J. H.

Blast-furnace and like gases; Pre-heating —— in dry gas-purifying plants. Dinglersche-Maschinenfabrik A.-G. E.P. 182,102, 1.6.22. Conv., 24.6.21.

In preheating blast-furnace and like gas by surface radiators heated by gas burners, compressed air is supplied to the gas burners, thereby avoiding the use of exhaust fans for drawing off the hot gases of combustion. Independent gas burners are preferably employed for the heaters of the individual units.—A. R. M.

By-products; Apparatus and process for recovering —— from distillate gases. A. Roberts. E.P. 184,507, 12.2.21.

In the recovery of by-products from distillate gases, *e.g.*, coke-oven gas, a suitable medium is injected for the purpose of increasing the vapour tension and lowering the temperature of the gas to that slightly above the dew-point of the heaviest constituent to be removed. The gas is then passed through a series of condensers, which may be jacketed if desired, and are each maintained at the dew-point of the constituent to be separated. Oils, emulsions or other by-products, having substantially the same composition as the by-products subsequently removed at a later stage of the process, are sprayed into the condensers, and are evaporated therein, serving at the same time to condense the heavier constituent which it is desired to remove. An ammonia saturator may be located at such a point in the system that gas entering it has its temperature above the dew-point of water vapour, so as to avoid excessive condensation of water in the acid. To remove products the dew points of which are lower than that of water-vapour, *e.g.*, benzol from coke-oven gas, a condenser is placed after the ammonia saturator and the gas sprayed therein with a suitable liquid, after suitable preliminary cooling.—A. R. M.

Alcohol fuel. J. Hawes. E.P. 184,607, 27.5.21.

The fuel consists of 96—98% alcohol, 96 pts.; petroleum naphtha, 2 pts.; nitrobenzene, 1 pt.; and amyl alcohol, 1 pt.—T. A. S.

[Hydrocarbon] oils; Process and apparatus for catalysing —— and revivifying the catalyst. E. V. Owen, Assr. to The Hoover Co. U.S.P. 1,427,626, 29.8.22. Appl., 31.3.22.

Low-boiling hydrocarbons are produced by passing high-boiling hydrocarbons with "aluminium chloride hydrocarbon catalyst" through a catalysing chamber maintained at a suitable temperature. After passing through the catalysing chamber the oil is separated from the catalyst and returned to the chamber. The returning oil passes along the outer wall of the catalysing chamber and is heated to maintain the chamber at the correct temperature. Low-boiling hydrocarbon vapours are removed from the chamber.—T. A. S.

Mineral oils and the like; Process for refining ——. Plauson's Forschungsinstitut G.m.b.H. G.P. 352,189, 11.3.20.

Alkali bisulphates or pyrosulphates are used, at temperatures between 110° and 250° C., if necessary under pressure, the sulphur dioxide produced being converted into sulphuric acid, which is used to produce bisulphates from the alkali sulphates recovered from the residues. The saturated hydrocarbons are scarcely attacked and are recovered in a high degree of purity.—A. G.

Hydrocarbon oils; Process for the purification of ——. Deutsche Erdöl-A.-G. G.P. 352,917, 18.2.21.

The oils are treated with more than 5% of paraffin monocarboxylic acids or their halogen derivatives or anhydrides until colourless and odourless, and free from resin and asphalt. Mineral oil is treated, *e.g.*, with acetic acid or concentrated formic acid, with stirring, or, in a continuous process, in a packed washing column on the counter-current principle. The process is simpler and cheaper than that using sulphuric acid.—A. G.

Paraffin; Continuous production of ——. W. Scheffer. G.P. 353,780, 23.11.17. Addn. to 352,919 (J., 1922, 661 A).

The melting process is employed in the absence of air. Danger from fire is minimised and an increased yield is obtained.—A. G.

Sulphonic acid [from mineral oils]; Process of cleaning [removing inorganic salts from] ——. A. Wolff, Assr. to The Chemical Foundation, Inc. U.S.P. 1,428,197, 5.9.22. Appl., 20.4.16.

Inorganic salts are removed from sulphonic acids prepared by treating mineral oils with sulphuric acid, by washing at about 140° F. (60° C.) with a quantity of 40—50% sulphuric acid approximately equal to 20% of the weight of the sulphonic acids under treatment.—L. A. C.

Raw peat and the like; Process of drying and compressing ——. A. J. H. Haddan. From Torfverwertungsges. Pohl und von Dewitz. E.P. 165,445, 10.5.21. Addn. to 158,513 and 159,464.

See G.P. 342,337 of 1920; J., 1920, 130 A.

Gasfication of coal or other carbonaceous material. A. McD. Duckham. U.S.P. 1,428,421, 5.9.22. Appl., 2.5.21.

See E.P. 164,935 of 1920; J., 1921, 572 A.

Methane and hydrogen; Apparatus and method for production of a gaseous mixture of ——. L. Colson. U.S.P. 1,428,879, 12.9.22. Appl., 12.12.18.

See E.P. 121,124 of 1918; J., 1919, 620 A.

Mineral oils obtained from earth oil; Method of refining ——. C. R. Ehlers. E.P. 184,991, 29.7.21.

See G.P. 348,342 of 1920; J., 1922, 362 A.

Motor fuel; Aeroplane ——. W. T. Schreiber, Assr. to U.S. Industrial Alcohol Co. U.S.P. 1,428,913, 12.9.22. Appl., 25.6.18. Renewed 11.8.19.

See E.P. 128,915 of 1919; J., 1920, 651 A.

Lubricating oils. G.P. 352,726 and 353,497. *See* III.

Iron oxide sludge. U.S.P. 1,428,521. *See* VII.

Lubricating oils etc. G.P. 353,222. *See* XII.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Thermal conductivity at temperatures of incandescence [e.g., of incandescence filaments]; Determination of ——. M. von Laue and W. Gordon. Sitzungsber. Preuss. Akad. Wiss. Berlin, 1922, 112—117. Chem. Zentr., 1922, 93, IV., 689.

The thermal conductivity of the filaments of electric lamps in a state of incandescence may be determined by heating the filament with alternating current and measuring the difference in phase between the temperature and the heat liberated, or by determining the variations in the temperature of the surface of the filament. The variations in the electrical and thermal conductivity, due to local or temporary variations in temperature, may be neglected. The variations in temperature must not be too great. The filament must be of such a length that the flow of heat to its ends does not need to be taken into consideration.—A. B. S.

Patents.

Peat and the like; Dry distillation and coking of raw ——. A. J. H. Haddan. From Torfverwertungsges. Pohl u. [illegible]n Dewitz. E.P. 169,952, 10.5.21. Addition [illegible] 158,513 (*cf.* G.P. 337,097; J., 1921, 618 A).

A modification of the original process in which the moisture of the peat is liberated by heating only a selected zone of the charge, preferably the interior, or heating one zone more powerfully than the surrounding zones, and allowing the steam thus generated to penetrate the charge and expel the moisture to an outlet or outlets. A water discharge pipe has a stop-cock which can be kept closed until the water to be discharged has collected in the pipe.—A. R. M.

Carbonisation of coal, shale, peat, and the like; Apparatus for ——. H. P. Hird. E.P. 184,525, 20.12.21.

Within the carbonising retort a shaft or shafts of suitable cross-section are caused to revolve, so that a passage is formed within the body of the charge, external to the shaft, thus permitting ready escape of gas from the retort. A tapering shaft may be used, and it may have a combined reciprocating and rotary motion.—A. R. M.

Pitch and the like; Carbonisation of ——. K. Kubierschky. G.P. 354,213, 30.11.20.

Pitch is worked up into solid briquettes by admixture while hot with coke, coal, or sawdust, and the product is distilled. The coke formed during distillation can be readily removed from the retorts. —L. A. C.

Wood and similar materials; Method for obtaining chemical products from ——. Chem. Fabr. Kalk G.m.b.H., und H. Oehme. G.P. 354,865, 7.4.20.

A dry mixture of wood flour and magnesium chloride is heated in a current of dry steam and the products of decomposition of the wood, such as acetic acid, methyl alcohol, acetone, furfural, etc., are partly removed during the process of decomposition and finally by steam distillation. The residue is used in the preparation of artificial wood and similar products.—A. J. H.

Electric discharge tubes [*; Gas-filled —— with independent discharge*]. Naaml. Vennoots. Philips' Gloeilampenfabrieken. E.P. 162,268, 18.2.21. Conv., 20.4.20.

In gas-filled electric discharge tubes in which an electric discharge is started by supplying current to the electrodes, the starting potential is reduced by combining magnesium or beryllium or their alloys with the metal, *e.g.*, iron or aluminium, forming the electrodes. Thus magnesium or beryllium may be mechanically applied to the electrodes, and material disintegrated from the electrodes by the discharge is prevented from forming a deposit upon the walls of the discharge tube by suitably shaping the electrodes, *e.g.* by partly surrounding the auxiliary metal or alloy by the electrodes.
—J. S. G. T.

Distillation of material carrying a percentage of volatile matter [*e.g., shale etc.*]. G. McD. Johns, Assr. to The Industrial Process Engineering Co. U.S.P. 1,423,527, 25.7.22. Appl., 16.7.20.

See E.P. 172,392 of 1920; J., 1922, 92 a.

Carbonaceous materials; Heating of vertical retorts for the distillation of ——. W. Wild, Assr. to West's Gas Improvement Co., Ltd. U.S.P. 1,427,426, 29.8.22. Appl., 5.6.20.

See E.P. 153,139 of 1919; J., 1920, 813 a.

[*Incandescence electric lamps;*] *Hermetical seal* [*for leading-in wires of ——*]. W. L. Van Keuren, Assr. to General Electric Co. U.S.P. 1,427,870, 5.9.22. Appl., 15.6.18.

See E.P. 130,212 of 1918; J., 1919, 675 a.

III.—TAR AND TAR PRODUCTS.

Low-temperature coal-tar and pitch therefrom [*; Composition of ——*]. J. Marcusson and M. Picard. Z. angew. Chem., 1922, 35, 493—494.

The presence of carboxylic acids in low-temperature tar previously reported by the authors (*cf.* J., 1921, 462 a) has been confirmed by examination of two other industrial samples. These acids are considered to be not phenolcarboxylic acids but acids allied to humic acid, as are similar compounds found in wood-tar. Pitch from low-temperature tar and ordinary coal-tar pitch of similar melting points show wide differences in composition. Determinations of the degree of softness by the Richardson penetrometer and of the elasticity of different qualities of pitch from low-temperature tar and pitch derived from ordinary coal tar and lignite tar are given. These properties are of importance from the point of view of suitability for the preparation of asphalt. In the case of material derived from coal, pitch from low-temperature tar is far inferior to a similar quality of ordinary pitch for this purpose. With lignite pitch the difference is not quite so great.—C. I.

Benzol; Estimation of —— in gas. H. Bähr. Chem.-Zeit., 1922, 46, 804.

The apparatus consists of a jacketed metal cylinder, the inner portion of which is filled with activated charcoal. This cylinder is placed in a vertical position and the gas is passed into it after passing through a gas meter. After the absorption the cylinder is placed horizontally, the jacket partly filled with naphtha of b.p. 160°—170° C., and the latter heated to boiling, while a current of superheated steam is passed through the charcoal. The benzol is condensed and the vessel finally swept out with heated gas. Tests with this apparatus showed that at two coke-oven installations some 20% of the benzol was escaping absorption. Part of this loss, however, is inevitable, the charcoal apparatus recording as benzol fractions of very low boiling point which could not be retained by wash-oil.
—C. I.

Patents.

Tar; Distillation of ——. Thermal Industrial and Chemical (T.I.C.) Research Co., Ltd., J. S. Morgan and D. Rider. E.P. 184,624, 7.6. and 20.12.21.

The difficulties of frothing in tar-stills and the removal of constituents of lower boiling point from viscous pitch are overcome by feeding the crude preheated tar under the surface of molten metal which is kept at such a temperature that hard pitch is discharged. The vapours from the still, which is kept at about 350° C., are passed through a small fractionator, kept by the incoming tar at about 120° C. The vapours leaving at this temperature consist of water and light oils. The condensed liquid from the fractionator is led into a secondary still also containing molten metal and maintained at about 230° C. This removes the usual tar fraction boiling at 170°—230° C. The residues pass on to a third still kept at 270° C. where the fraction boiling at 230°—270° C. is removed. The residue constitutes another well-marked fraction boiling between 270° and 350° C. A modification of the process consists in keeping the first still at 275°—290° C., whereby the anthracene remains in the pitch. The pitch is then sprayed in a tower with superheated steam which removes the anthracene.
—T. A. S.

Waste sulphuric acid [*from refining tar oils*]*; Process for treatment of ——* [*to recover resinous products*]. S. Hilpert, Assr. to Deutsch-Luxemburgische Bergwerks und Hütten A.-G. U.S.P. 1,427,386, 29.8.22. Appl., 9.7.21.

The waste sulphuric acid obtained in the purification of light coal-tar oils is treated with an aromatic hydrocarbon to recover resinous products.—T. A. S.

Lubricating oils; Production of highly viscous —— from coal-tar oils. Chem. Fabr. Worms A.-G. G.P. 352,726, 8.12.17. Addn. to 350,801 (J., 1922, 539 a).

Acid gases, particularly gaseous hydrogen chloride, are used as condensing media, and are brought into contact with the oils at high pressures and elevated temperature. Anthracene oil is saturated with hydrogen chloride in an autoclave, the charge being stirred at about 100° C. under pressure of 1—2 atm. until a sample shows the desired viscosity. The viscosity increases from 4·52° Engler at 40° C. to 12·5° Engler at 50° C. Sulphur dioxide may be used in place of hydrogen chloride.—A. G.

Thionaphthenesulphonic acid; Process for preparing ——. Ges. für Teerverwertung m.b.H., and R. Weissgerber. G.P. 353,932, 22.2.21.

The sulphonation of thionaphthene is carried out in the presence of at least sufficient acetic anhydride to combine with the water present in the sulphuric acid and that produced during the reaction. The free acid is a difficultly crystallisable, syrupy mass, easily soluble in water. The potassium salt forms colourless easily soluble laminæ. The acid is decomposed on heating with dilute sulphuric acid to 140° C. into thionaphthene and sulphuric acid.
—H. C. R.

Purification of waste liquid [*containing hydrocarbons*]. F. W. Wagner. U.S.P. 1,428,618, 12.9.22. Appl., 24.8.20.

Hydrocarbon compounds are removed from aqueous solutions by passing a stream of a reducing gas through and intimately mingling it with the solution in presence of a catalyst.—B. M. V.

IV.—COLOURING MATTERS AND DYES.

Colour of the azo-dyes and related coloured substances; Calculation of the ——. J. Moir. Chem. Soc. Trans., 1922, **121**, 1555—1562.

The method of representing coloured substances by hydroxylated formulæ which may then be dissected into a fundamental skeleton or parent substance and a number of subsidiary groups or linkages (Chem. Soc. Trans., 1921, **119**, 1655), has been successfully applied to the simpler azo-dyestuffs, and numerical values have been found for the subsidiary groups, so that, for example, the colour of ionised benzene azophenol or the wave length of the absorption band may be calculated from that of ionised phenol as parent substance, by multiplying its wave length ($\lambda = 287$) successively by the respective numerical factors for the subsidiary groups. From the values for the hydroxy-compounds those for the aminoazo- and dimethylaminoazo-compounds can be calculated by using the factors for the ratios NH_2/OH and $(CH_3)_2N/OH$, viz., 1·1 and 1·19 for the lower bands and 1·18 and 1·27 for the higher bands respectively. By introducing other interposition factors the values for azomethine, stilbene, and higher azo-dyestuffs can be calculated. The following are colour factors for groups interposed in the chain: $—CH_2—$ 0·92, —NH— 1·09, —O— 1·0 and 1·4, —CHOH— 1·01, —NOH— 1·20; as second linkage to two rings the factor for $—CH_2—$ is 0·95, —NH— 1·13, and —O— 1·02 and 1·4. The naphthalene/benzene factor is 1·15, and the phenyl factor 1·135.—G. F. M.

Cyanine dyes. V. Virtual tautomerism of the thiocyanines. W. H. Mills and W. T. K. Braunholtz. Chem. Soc. Trans., 1922, **121**, 1489—1495.

The thiocyanines produced by the condensation of 5-methylbenzothiazole ethiodide with 1-methylbenzothiazole ethiodide on the one hand, and 1.5-dimethylbenzothiazole ethiodide with benzothiazole ethiodide on the other hand, are identical substances, whereas in the absence of any intramolecular change, two isomeric thiocyanines would have been expected, differing in the nitrogen atoms to which the acid radicle was attached. The facts therefore demonstrate the existence of virtual tautomerism in this class of dyestuffs, involving the transference of the acid radicle from one of the two nitrogen atoms to the other with a correlated shift in the conjugated double linkings of the connecting chain. In view of the close correspondence in properties between the various classes of cyanine dyestuffs, there can be little doubt that the other classes of this group, the cyanines, carbocyanines and their isomerides, are capable of showing the same phenomenon.—G. F. M.

Pyrylium salts of anthocyanidin type; Synthesis of ——. D. D. Pratt and R. Robinson. Chem. Soc. Trans., 1922, **121**, 1577—1585.

Derivatives of 3-hydroxybenzopyrylium salts related to the naturally occurring anthocyanin plant pigments have been synthesised by condensation of *o*-hydroxyaldehydes and ω-alkyloxy- or ω-aryloxy-acetophenones. The direct condensation is exemplified by the preparation of 7-hydroxy-3-ethoxy-2-phenylbenzopyrylium chloride by passing hydrogen chloride into a glacial acetic acid solution of β-resorcylaldehyde and ω-ethoxyacetophenone. It forms orange-red needles which decompose at 210° C., and gives a ferrichloride in the usual way, crystallising in diamond-shaped prisms, m.p. 170° C. 3-Ethoxy-2-phenylbenzopyrylium ferrichloride was, on the other hand, obtained by two steps, first the preparation of phenyl-2-hydroxy-β-ethoxystyryl ketone from salicylaldehyde and ω-ethoxyacetophenone, and secondly the conversion of the styryl ketone into a pyrylium chloride by means of hydrogen chloride in dry ethereal solution. The ferrichloride crystallises in bright golden plates, m.p. 121° C.—G. F. M.

Naphthalene and its derivatives; Electrolytic reactions of ——. *III. Electrolytic oxidation of α-naphthylamine and ar-tetrahydro-α-naphthylamine.* K. Ono. Mem. Coll. Sci. Kyoto Imp. Univ., 1922, **5**, 345—357.

α-Naphthylamine is oxidised electrolytically in a divided cell in which a small sheet lead cathode is immersed in sulphuric acid (20%) and the anode liquid is a solution of α-naphthylamine in acetone and dilute sulphuric acid. Platinum, graphite, and lead peroxide respectively may be used as anode materials, the last-named giving the best results. Under these conditions, α-naphthylamine is converted into a mixture of Naphthylamine Violet and α-naphthoquinone. Its behaviour thus differs from that of aniline which, at a platinum electrode, is transformed solely into Aniline Black, but the apparent stability of the latter may be due entirely to its insolubility in the anode liquid. The current yield diminishes with increasing current density but attains its maximum at approximately 1 amp. per 100 sq. cm. Raising the temperature of the electrolyte does not necessarily favour the yield. A suitable concentration of sulphuric acid is 10—30%, the best results being obtained with a 10% solution. Potassium chromate, chrome alum, potassium chlorate, and ferric sulphate act effectively as oxygen carriers. Under closely similar conditions, *ar*-tetrahydro-α-naphthylamine is oxidised to *ar*-tetrahydro-α-naphthoquinone. Platinum, lead peroxide, and graphite may be used as anode material and, of these, lead peroxide gives the best results. The most suitable conditions are a current density of about 1 amp. per 100 sq. cm., a temperature between 18° and 23° C., and a concentration of sulphuric acid between 10% and 30%. Chrome alum, potassium chromate, potassium chlorate, and potassium ferrocyanide are efficient oxygen carriers. —H. W.

Triphenylpararosaniline hydrochloride; Formation of —— *from diphenylamine and chloral-ammonia.* R. Horiuchi. Mem. Coll. Sci. Kyōtō, 1921, **5**, 1—7.

The small yield of triphenylpararosaniline hydrochloride obtained by heating diphenylamine and chloral-ammonia directly to 130° C. is greatly increased by maintaining the temperature at 100° C. for some time prior to heating to 130° C. The author has investigated the reaction of diphenylamine with various compounds containing the CCl_3 and CHO groups respectively and concludes that compounds containing the former group are alone concerned in the formation of Diphenylamine Blue, the chlorine atoms being replaced by the phenyl group, and the resulting product reacting with part of the hydrogen chloride produced. —J. S. G. T.

Carbamides of anthraquinone. M. Battegay and J. Bernhardt. Chim. et Ind., 1922, **8**, 305—306.

The three isomeric dianthraquinonylcarbamides show a gradation in properties in which the αβ′-isomeride approaches more nearly to the

$\beta\beta'$-isomeride than to the $\alpha\alpha'$-isomeride. The two first-named may be used as vat dyes by preliminary reduction with alkaline sodium hydrosulphite at 30°—40° C., but under similar conditions the $\alpha\alpha'$-isomeride undergoes hydrolysis unless the temperature is kept below 18°—20° C., and then the material is so insoluble as to render it useless as a dye. If, however, two hydroxy, methoxy, or benzoylamino groups are introduced in para positions to the carbamide group, one in each anthraquinonyl nucleus, then the products are stable in the reducing bath and may be used as dyes.—W. G.

Urethanes of anthraquinone. M. Battegay and J. Bernhardt. Chim. et Ind., 1922, 8, 307.

The urethane group exercises a greater auxochrome effect when introduced into the anthraquinone molecule than does the benzoylamino group, both in the α and the β derivatives. The α-urethanes, like the $\alpha\alpha'$-carbamides, on reduction in alkaline medium give products which are immediately hydrolysed, and this is not checked in the case of the urethanes by the introduction of a nitro, hydroxy, methoxy, or benzoylamino group into the para position prior to the reduction.—W. G.

Patents.

Anthraquinone dyestuffs; Manufacture of ——. F. W. Atack and C. W. Soutar. E.P. 185,137, 23.2.21.

The dull shade of halogenated N-dihydro-1.2.2′.1′-anthraquinoneazine dyestuffs, which are obtained by condensation of halogenated aminoanthraquinones in the presence of a copper salt, is due to the presence of traces of impurities which are rendered soluble and therefore capable of easy removal, by halogenation of the crude dyestuff. For this purpose, the crude dyestuff is treated in suspension or solution in an inert liquid with chlorine or bromine or substances which produce these *in situ.* When purified by this process, 3.3′-dibromo-N-dihydro-1.2.2′.1′-anthraquinoneazine yields a dyestuff having a redder and purer blue shade.

—A. J. H.

Acridine series; Compound of the —— and a process of making the same. Acridinium compounds and a process of making the same. L. Benda, Assr. to L. Cassella und Co. G.m.b.H. U.S.P. (A) 1,427,431, and (B) 1,427,432, 29.8.22. Appl., 14.7.21.

(A) 3.6-Diamino-10-alkylacridinium compounds are treated with formaldehyde in the presence of dilute mineral acids at the ordinary temperature. (B) Readily-soluble salts of 3.6-diamino-10-methylacridinium are treated with tannin in the presence of acid-binding agents, yielding a tasteless, bright orange-yellow powder suitable for use in the manufacture of lake colours.—L. A. C.

Isatin-α-arylides; Process for the preparation of compounds of —— with sulphur dioxide. C. Stephan. U.S.P. 1,427,863, 5.9.22. Appl., 24.8.21.

The acid mixtures produced by interaction of isatin-α-arylides and sulphuric acid are treated with basic sulphites in such a manner that the sulphuric acid is neutralised rapidly and completely before decomposition of the sulphites can take place.

—L. A. C.

[Triphenylmethane] dyestuffs; Manufacture of chlorinated products of toluene and —— therefrom. J. Schmidlin, Assr. to L. Cassella und Co. U.S.P. 1,428,984, 12.9.22. Appl., 12.3.15.

See E.P. 13,970 of 1915; J., 1915, 1243.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Pines and spruces; Investigations on Swedish ——. H. E. Wahlberg. Svensk Pappers-Tidning, 1922. Papierfabr., 1922, 20, 1097—1100, 1133—1137, 1178—1181.

Numbered discs and sectors were cut from test stems of spruce and pine and subjected to a close systematic examination. In the spruce the limits between heart and sapwood are not very clearly defined but could be distinguished after staining with perosmic acid. The heart wood does not extend equally in all radial directions, but the differences do not cover more than one or two annual rings. For the estimation of moisture the wood was exposed *in vacuo* for 72 hrs. at the ordinary temperature over phosphorus pentoxide. In a sector which was closely studied the specific gravity of the whole sector, dried *in vacuo*, was 0·345; that of the spring wood was 0·307 (average), and that of the autumn wood 0·601. A cold, wet season apparently tends to give rise to wood of lower density. The shrinkage in volume of the freshly felled wood in drying to the air-dry condition ranged from 6·5 to 11·6%. The ash constituents were slightly concentrated in the outer and higher portions of the stem. Estimations of fat and resin vary greatly according to the solvent employed; the determinations were made by extracting first with benzene for 8 hrs. and then with alcohol for the same length of time. Storage for 80 days made no difference in the resin values as compared with storage for 10 days; any modification of the resin after felling must therefore have been complete in the first 10 days. Drying at 105° C. considerably decreased the amount of benzene extract. The distribution of resin in the stem was irregular, but the general tendency was for the resin to increase from the outside towards the heart; its distribution was more regular near the apex of the stem where no secondary processes had taken place. Cellulose was determined by digestion for 18 hrs. with bisulphite solution at 125° C., followed by repeated treatments with bromine. The percentage of cellulose did not show large variations, but small variations were observed which were in the reverse direction to the variations in the resin-content.

—J. F. B.

Wood; Cellulose value of pulp ——. H. E. Wahlberg. Papierfabr., 1922, 20, 1216—1218.

The percentage of cellulose in wood, calculated on the resin-free dry weight, shows only minor variations round about an average of 49—51%. The yield of cellulose is lowest at the centre of the stem and this is due either to secondary changes which render the fat and resin insoluble in the extraction media or to the presence of increased quantities of other non-cellulose compounds, such as lignin. The apparent specific gravity of the wood, however, is subject to large variations, and since pulp-wood is always dealt with in terms of volume rather than weight, the cellulose value at the pulp mill is subject to corresponding variations. The cellulose value, kg. of pulp per cub. m. of solid wood, may be expressed by the formula $m=K(100-h)S$, where K is practically a constant depending on the method of digestion, S is the apparent specific gravity, when the volume is measured on the moist wood and the weight is the dry weight, and h is the percentage of resin. In the method employed by the author for the determination of cellulose (digestion with bisulphite at 120° C. and repeated bromination) the value of K could be taken as 5. The area of the disc of wood was determined by tracing its outline on a sheet of paper of known area-weight and weighing the paper template. In calculating the cellulose value of the whole stem by the above formula the stem was divided into four equal lengths and a sample disc was cut from the middle of each, the area of the discs being taken to represent the quantitative value of the portion of the stem from which it was cut. Examined in this way, two stems of spruce, grown under equally favourable conditions, gave cellulose values of 125 and 263 respectively, and a stem of pine grown on poor soil showed a cellulose value of 220 kg. per solid cubic metre. Hence it follows that different trees of the same origin have very different values for the pulp maker owing to differences in the specific gravity of the wood, ranging from 0·348 to 0·551.—J. F. B.

Cellulose; Viscosity of —— in cuprammonium hydroxide solution. I. Determination of the viscosity. R. A. Joyner. Chem. Soc. Trans., 1922, 121, 1511—1525.

IMPROVEMENTS have been made in the falling-sphere viscosimeter method of Gibson, Spencer, and McCall (J., 1920, 541 A, 558 A) for determining the viscosities of cuprammonium solutions of cellulose. A different method for the preparation of the Schweitzer reagent was used, the solution being made by bubbling air through a mixture of copper turnings in strong ammonia, with the addition of about 1 g. of sucrose per litre to hasten the dissolution of the copper. Solutions containing more than 30 g. of copper per litre can be obtained, and by determining the copper and ammonia in the usual way solutions of any desired strength can be prepared by suitable dilution. A modification of the method of preparing the cellulose solutions and filling the viscosimeter tube was developed, in order to eliminate errors due to oxidation and to the presence of air bubbles in the viscous solutions. The cotton was packed in a glass tube, 5 cm. wide and 10 cm. long, drawn out at each end to a narrow tube 0·7 cm. wide, and connected below with rubber tubing to the bottom of the viscosimeter tube on the one hand, and above through suitable taps to a reservoir containing the reagent, and sources of vacuum and pressure. The tube was evacuated, the copper reagent admitted, any residual air removed by further suction, and the tube was finally closed and shaken to dissolve the cellulose. Finally by means of slight pressure (air is quite suitable provided the top layers of the solution are rejected) the solution was transferred to the viscosimeter tube. An increase of about 12% on Gibson, Spencer, and McCall's figures was observed by the new method. Experiments were undertaken to determine the effect of the concentration of copper and ammonia, and small percentages of sucrose or salts on the viscosities. The latter had no appreciable effect. The best copper concentration for general use is 13 g. per litre with 20 g. of cellulose and 200 g. of ammonia per litre. With low viscosity cotton a 4% solution of cellulose is necessary; this is prepared with a reagent containing 20 g. of copper and 200 g. NH_3 per litre, and the viscosity for a 2% solution is calculated by the Arrhenius formula.
—G. F. M.

Rubber latex in paper making. F. Kaye. India-rubber J., 1922, 64, 435—442.

RUBBER latex is introduced during the beating process, a coagulant such as magnesium sulphate, acetic acid, or alum being added if necessary. The process of hydration involved in beating is accelerated even by small quantities of latex, while the tensile strength and bursting strain of the paper are increased in a marked degree. The rubber, which may conveniently amount to approximately 1% of the paper, is as durable and resistant to spontaneous chemical change as the paper itself.
—D. F. T.

Paper; Determination of mechanical wood pulp in printing ——. H. Krull and B. Mandelkow. Papierfabr., 1922, 28, 1213—1216.

THE determination of the phloroglucinol absorption value, carried out exactly according to the method of Cross, Bevan, and Briggs (J., 1907, 942), affords a convenient and accurate measure of the percentage of mechanical pulp in "news" and similar printing papers. In calculating the results, however, the original factors 8 for mechanical wood and 1 for sulphite pulp cannot be accepted as sufficiently accurate. The true average values for these factors are 7·84 for mechanical and 1·34 for unbleached strong sulphite pulps. The error involved by using the original factors is negligible for papers containing between 65 and 75% of mechanical wood pulp, but becomes very considerable in the case of papers containing low percentages of that constituent. The corrected formula for calculating the result, expressed on the dry substance, is $H = 100(P-1{\cdot}34)/(7{\cdot}84-1{\cdot}34)$, where H is the percentage of mechanical pulp and P is the phloroglucinol absorption value of the paper.—J. F. B.

PATENTS.

Viscose; Manufacture and treatment of ——. Plauson's (Parent Co.), Ltd. From H. Plauson. E.P. 184,533, 11.4.21.

MONOSODIUM- (or disodium-)viscose is made from highly dispersed cellulose (*cf.* E.P. 183,908; J., 1922, 748 A); *e.g.*, monosodium-viscose is made by treating a paste containing 32 pts. of cotton, 8 pts. of caustic soda, and 600—800 pts. of water in a colloid mill for ½—1 hr., and then adding 7—8 pts. of carbon bisulphide; after treatment for a further 10 mins. in the mill the reaction is complete. The viscose solution thus obtained may be filtered, and, if required for the manufacture of artificial silk, concentrated *in vacuo* at temperatures not above 40° C. to the required strength, or the viscose may be coagulated by heating it at 80°—100° C., in which case resin, rubber, etc. may be added during the dispersion treatment to modify the properties of the final product. By adding to the viscose solution a non-injurious electrolyte, *e.g.*, salt, viscose is precipitated and after washing and drying remains as a fine water-soluble powder, which, however, gradually changes into an irreversible colloid unless kept *in vacuo*, or in an atmosphere of an inert gas such as nitrogen or hydrogen. This powder may be used for the preparation of compact masses by heating it in moulds at 120°—150° C. under 200—500 atm. pressure. The advantages claimed for this process are that theoretical quantities of alkali and carbon bisulphide are used, the whole operation is rapidly carried out, and the viscose produced requires very little "ripening" even when used for the manufacture of artificial silk.
—D. J. N.

Hydra-oxy-cellulose, a xanthogenated compound obtained therefrom and a solid compact material obtained by coagulation of the latter; Manufacture of ——. C. C. L. G. Budde. E.P. 184,610, 28.5.21.

BY treating cellulosic material containing one half to twice its weight of water first with chlorine gas in sufficient excess to react with the non-cellulose matter and convert the cellulose into oxycellulose, and then with strong hydrochloric acid, a hydra-oxy-cellulose is obtained. This substance gives a xanthate, which readily mixes with water—a solution containing 20% of hydra-oxy-cellulose will spread itself evenly and rapidly over a flat surface—and can be used for the manufacture of artificial silk, paper size, leather boards, etc. The process may be conducted, for example, as follows: Wood pulp (100 pts.) reduced to the size of small crumbs with an equal weight of water, is exposed for some hours to the action of chlorine gas until about 10 pts. by weight of chlorine has been absorbed. Materials such as oat straw require 30—50% of chlorine gas. The oxycellulose thus obtained is air-dried to concentrate the hydrochloric acid (a by-product in the chlorination process) and convert the oxycellulose into hydra-oxy-cellulose. The resulting brittle product is transferred to a mixing machine with 275 pts. of an 18% solution of caustic soda, and, after mixing for about 2 hrs., 40 pts. of carbon bisulphide is added: the reaction is allowed to proceed for about 4 hrs., with cooling if necessary. The solution obtained may be used for all purposes for which viscose is used, but is particularly suitable for the manufacture of compact solid bodies, *e.g.*, a 16% solution (16% hydra-oxy-cellulose) with addition of such fillers as zinc oxide, clay, starchy matter, paper pulp, esparto resin, waxes, fats, resins, glycerin, dyes, etc., is poured into moulds, and, when free from air bubbles, heated to 40° C. for about 12 hrs. when a homogeneous compact mass is obtained. This is dried, either direct or after washing in a current of water at 50° C., and if a waterproof product is required, heated at or above 100° C. Imitation leather may be made by mixing 50 pts. of zinc oxide and 50 pts. of resin oil with the xanthate derived from 100 pts. of hydra-oxy-cellulose, and impregnating the product with glycerin.—D. J. N.

Cellulose derivatives [acetate]; Manufacture of solutions, compositions, preparations or articles made with ——. H. Dreyfus. E.P. 184,671, 20.7.21.

Cyclobutanone (b.p. 99°—101° C.), either alone or in admixture with other solvents, such as methyl or ethyl alcohol, acetone, methyl acetate, etc., is used as a solvent for cellulose acetates in the manufacture of varnishes, plastic masses, and the like. Cellulose acetate varnish, for example, may be made by dissolving 100 pts. of cellulose acetate in 1000 pts. of cyclobutanone or in 100—500 pts. of cyclobutanone and 900—500 pts. of methyl acetate or acetone; a plastic mass may be made by dissolving 100 pts. of cellulose acetate and 12—15 pts. of triphenyl phosphate in 50 pts. of cyclobutanone and 100 pts. of methyl acetate, acetone, or alcohol. —D. J. N.

Spun material resembling wool, cotton, or chappe; Process for producing —— from viscose solutions. P. H. Minck, Assr. to The Chemical Foundation, Inc. U.S.P. 1,428,246, 5.9.22. Appl., 16.5.19.

Cellulose material is treated with a solution of a caustic alkali sufficient to produce incomplete hydration without an excess of water, and is then treated with carbon bisulphide and the cellulose xanthate thereby formed is dissolved in a 3—5% solution of caustic alkali and afterwards spun in a bath containing a mineral acid.—A. J. H.

Cellulose esters and ethers; Composition and film containing mixtures of ——. L. J. Malone, Assr. to Eastman Kodak Co. U.S.P. 1,429,153, 12.9.22. Appl., 7.1.22.

The composition consists of 1 pt. of a mixture of a cellulose ester and a cellulose ether dissolved in not more than 6 pts. of a liquid containing pyridine. —A. J. H.

Cellulose-ether composition. P. C. Seel, Assr. to Eastman Kodak Co. U.S.P. 1,429,169, 12.9.22. Appl., 5.1.22.

The composition contains a cellulose ether and dichloropropane.—A. J. H.

Cellulose ether solvent and composition. S. J. Carroll, Assr. to Eastman Kodak Co. U.S.P. 1,429,188, 12.9.22. Appl., 5.4.21.

A viscous composition suitable for producing films consists of a solution of an alkyl ether of cellulose in a mixed solvent containing 90 to 40 pts. of ethylene chloride and 10 to 60 pts. by weight of a lower monohydric aliphatic alcohol.—A. J. H.

Artificial silk filaments; Process for the manufacture of fine ——. Vereinigte Glanzstoff-Fabrik A.-G. G.P. 308,427, 7.4.18.

Regulated quantities of viscose solution are squirted into a coagulating bath under conditions (low temperature) such that the coarse filaments at first formed are incompletely coagulated and are then stretched to form very fine filaments. —A. J. H.

Cellulose threads; Method for quickly drying freshly precipitated ——. Vereinigte Glanzstoff-Fabrik A.-G. G.P. 312,393, 27.11.18.

The freshly precipitated cellulose threads are subjected to a suitable counter current of air, or other gas inert towards cellulose, at 100°—130° C. The threads do not suffer a loss of strength if they have been well washed and if the current of air is correctly adjusted to have a suitable thermal capacity.—A. J. H.

Cellulose xanthate [viscose] solutions; Preparation of —— suitable for the manufacture of threads. R. Linkmeyer. G.P. 337,672, 31.5.19.

In the preparation of viscose solutions, the crude brown cellulose pulp is boiled with acids before conversion into xanthate. Thread prepared from the resulting viscose solutions possesses a high breaking strain and can be satisfactorily used as a substitute for cotton. The breaking strain and lustre of the thread increase with the concentration of the viscose solution employed.—A. J. H.

Fibres; Process for making artificial ——, such as artificial silk, from cellulose ethers. Farbenfabr. vorm. F. Bayer und Co. G.P. (A) 352,191, 16.1.19, and (B) 352,192, 4.2.19.

(A) Saline solutions are used as a precipitating bath. Examples are calcium chloride solution of sp. gr. 1·3 at 15° C. or crystallised calcium chloride ($CaCl_2,6H_2O$) in the molten state at 70° C., or zinc chloride solution of sp. gr. 1·85 at 40° C. (B) Instead of saline solutions, substances may be used which are capable of taking up the solvent of, but do not act as a solvent or swelling agent for, the cellulose ether. For example, a 75% aqueous solution of urea may be used as the precipitating liquid.—H. C. R.

Artificial fibres; Manufacture of —— from solutions of cellulose in concentrated salt solutions. F. Beck. G.P. 353,662, 20.7.20.

The cellulose threads are coagulated by means of concentrated solutions containing the same salts as are used for preparing the cellulose solution. By this process the recovery of the salts is possible. —A. J. H.

Fibre liberation; Process of ——. G. A. Richter, Assr. to Brown Co. U.S.P. 1,427,125, 29.8.22. Appl., 21.2.21.

Cellulosic material is digested with a sulphurous acid solution of a soluble sulphate.—D. J. N.

Fibres and cellulose; Process for obtaining textile —— from plants containing much bast and little wood, such as flax straw, sisal, and jute. G. Odrich. G.P. 327,912, 22.1.18.

The raw material is first treated with hot water in the usual way and then with a 40—50% solution of sodium, potassium, magnesium, or magnesium-calcium bisulphite containing free acid at such a temperature that the bast fibres are not damaged. During the treatment and before the highest temperature is reached the lye becomes only weakly acid owing to the loss of sulphur dioxide from the boiling solution.—H. C. R.

Fibres; Process for the recovery of —— from mixtures. R. O. Herzog. G.P. 350,638, 15.5.20.

The disintegrated material is treated with a mixture of liquids such that each liquid wets one of the kinds of fibre. For example, a mixture of animal wool and vegetable fibre (cotton wool) is shaken with a mixture of water and an immiscible liquid, such as paraffin, carbon tetrachloride, or benzene. The animal wool collects at the dividing line between the two liquids and the cotton wool is taken up by the aqueous layer.—H. C. R.

Hair; Process for improving the textile qualities of human and animal ——. P. Krais and K. Biltz. G.P. 352,961, 28.7.20.

The hair is treated first with dilute alkali hydroxides, then with soap or organic solvents or with a mixture of soap solution and organic solvents. It is rinsed and then treated with solutions of calcium or magnesium chlorides or their mixtures, the excess of solution removed, and the hair dried at the ordinary temperature or slightly above it. Hair so treated is soft, flexible, and elastic and can be spun, without further treatment, either alone or mixed with wool, giving a round and uniform yarn.—H. C. R.

Felting; Preparatory treatment of hair for ——. Soc. du Feutre. G.P. 353,947, 29.12.20. Conv., 12.8.20.

Hair is treated with weak aqueous or feebly alkaline solutions containing the sulphide of an alkali or alkaline-earth metal, so that the so-called "ripening" of the hair is unnecessary and the treated hair can be directly employed in the operation of felting. Skins which have been treated with the hair on, may be tanned in the usual manner after the removal of the hair.—A. J. H.

Typha and rush fibres; Method for improving ——. J. Elster. G.P. 355,023, 18.5.18.

Typha and rush fibres are treated with strong caustic soda or with caustic potash or sodium sulphide and the like. The lower the temperature of treatment the more dilute may be the liquor used.
—A. J. H.

Cork substitute and process of manufacture. E. E. Graham. U.S.P. 1,427,682, 29.8.22. Appl., 14.1.20.

Wood is impregnated with an aqueous solution of sodium bicarbonate, and then with wood-ash lye, the temperature during both operations being maintained at 180° F. (82° C.).—D. J. N.

Paper; Process for the chemical and mechanical disintegration of raw materials used in the manufacture of ——. O. Herdey. G.P. 352,693, 9.10.20.

A rotary digester, a mixer, and a mechanical disintegrator, to which is attached a grading arrangement, are arranged so that after leaving the digester, the pulp is fed into the rotary mixer from which it passes into the disintegrator. The disintegration and grading of the fibrous material, usually carried out in separate stages, are thus effected in one process.—A. J. H.

Paper; Process for loading —— in the hollander. K. Joost. G.P. 354,544, 23.12.20.

During the rosin-sizing of paper pulp in the hollander, sulphates present are precipitated as calcium sulphate on the fibres by means of calcium chloride. Suitable additions of soluble compounds to the pulp may also be made, so that an increased amount of sulphate is precipitated and the paper pulp thereby loaded to a greater extent.—A. J. H.

Waste gases from chemical processes, especially from cellulose manufacture; Method of disposing of —— by burning. Zellstoff-fabrik Waldhof. G.P. 353,832, 21.5.19. Addn. to 304,999 (E.P. 115,350; J., 1918, 367 A).

Only a part of the waste gases is led with the primary air into gas-producers or similar plant and burnt there, the remainder being used with the secondary air for the combustion of the producer gas.—H. C. R.

Carrotting fur and hair. Soc. du Feutre. E.P. 167,748, 7.7.21. Conv., 12.8.20.

See G.P. 353,947 of 1920; preceding.

Cellulose ethers; Process for the manufacture of moulded articles from ——. G. Leysieffer. U.S.P. 1,427,690, 29.8.22. Appl., 7.1.21.

See E.P. 156,752 of 1921; J., 1921, 732 A.

Indurated materials; Methods of manufacturing —— from woven fabrics. British Thomson-Houston Co., Ltd. From General Electric Co. E.P. 185,662, 15.10.21.

Aluminium sulphate. G.P. 352,289. *See* VII.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Bleaching, past, present and future. G. Braam. Z. angew. Chem., 1922, 35, 501—502.

After reviewing past and present methods of bleaching the author describes a new apparatus for conveniently preparing an aqueous solution of chlorine when and where required. The apparatus is made of earthenware and consists essentially of an upper and lower chamber, the upper part of the upper chamber communicating with the bottom of the lower chamber, so that the water which initially fills the lower chamber is displaced into the upper chamber by introducing chlorine from a gas cylinder into the upper part of the lower chamber. The apparatus is provided with a graduated level gauge so that the amounts of water and chlorine respectively can be directly read off. After charging the apparatus in the manner described, the various cocks are closed and solution is rapidly effected by means of a small vulcanite propeller in the bottom of the apparatus which whirls the water on to the walls of the lower chamber, and as the gas is absorbed the water displaced into the upper container gradually flows back into the lower one, and the solution can be run off as required.
—G. F. M.

Bleaching of cotton with acid and alkaline liquors. E. Ristenpart. Textilber., 1922, 3, 363—364.

A critical investigation of the bleaching process described in G.P. 352,845 (J., 1922, 666 A) in which fibrous cellulose material is treated with acid and then with alkaline bleach liquors. When fabric which had been treated in an acid bleach liquor of 1° B. (sp. gr. 1·007) containing 2·5 c.c. of sulphuric acid per 500 c.c., was washed and then further treated in a similar but alkaline bleach liquor containing 1 c.c. of caustic soda of 32° B. (sp. gr. 1·285), it gained in strength and whiteness. When these bleaching treatments were reversed, the samples of fabric were inferior in strength and whiteness to that which had received the acid-alkaline bleach. Fabric, after an acid-alkaline bleach in liquors containing 1 g. of available Cl per l. was equal in appearance to but stronger than fabric which had been bleached in a liquor containing 4 g. Cl per l. In another instance, a similar result was obtained by using bleach liquors containing ½ g. and 2 g. of Cl per l. respectively. The process avoids the formation of oxycellulose and enables a large saving of bleaching powder to be effected.—A. J. H.

PATENTS.

Scouring, dyeing and similarly treating with liquids fabrics in piece form in continuous process; Apparatus for ——. M. Silbereisen. E.P. 176,306, 24.5.21. Conv., 2.3.21.

Fabric is continuously plaited down in open width, chain or rope form into one arm of a U-shaped vessel and is then forced forward by its own weight into the other arm, whence it is continuously withdrawn. The lower part of the U-bend in the vessel contains a false bottom consisting of numerous wooden rollers arranged parallel to each other and transversely to the axis of the U-vessel. The scouring or dye liquor, which passes through the apparatus in a direction opposite to that of the fabric, is also continuously circulated upwards between the rollers, between the folds of the fabric and at right angles to its direction of advancement in the U-bend.—A. J. H.

Vat-preparations for dyeing; Manufacture of stable, dry, and readily soluble ——. Farbw. vorm. Meister, Lucius, und Brüning. E.P. 177,526, 21.3.22. Conv., 26.3.21. Addn. to 171,078 (J., 1922, 705 A).

An alkali salt of a halogenindigo capable of dyeing wool from a vat is used instead of an alkali salt of leucoindigo in the process described in the chief patent. For example, a paste containing 250 kg. of monobromoindigo white and 100 kg. of the reduced brown sulphurised quinone vat-dyestuff prepared as described in E.P. 19,599 of 1912 (F.P. 447,592; J., 1913, 226), is dissolved in 300 kg. of sodium hydroxide solution of 40° B. (sp. gr. 1·383) and 300 kg. of water; 150 kg. of 50% molasses and 10 kg. of hydrosulphite are added, and the mixture is evaporated to dryness, first with agitation under high vacuum, and finally in shallow dishes *in vacuo*. The product is readily soluble in water and dyes wool reddish-black tints from a vat.
—L. A. C.

Vat dyestuff preparations for use in printing and dyeing; Manufacture of ——. C. Bennert. G.P. 353,866, 8.1.16.

Preparations containing vat dyestuffs, by means of which it is easy to prepare slightly alkaline or acidic dye vats, consist of a vat dyestuff in its leuco-form and a hydrolysis product of proteins, *e.g.*, protalbinic and lysalbinic acids and the like, or their salts (pure or impure) together with acids, acid salts, or neutral salts of volatile alkalis with organic acids, with the exception of organic hydroxy- and dihydroxy-acids and their anhydrides and salts.
—A. J. H.

Printing of textile fabrics. The Calico Printers' Assoc., Ltd., and G. Nelson. E.P. 185,007, 13.8.21.

Cotton fabric, after being mordanted with chrome and tannin, and dyed with a suitable dyestuff, is printed with a discharge paste containing a caustic alkali, with or without sulphoxylates, glycerin, and Rochelle salt for a white discharge, and together with vat dyestuffs for a coloured discharge, and is then aged, washed, and soaped in the usual manner. This process has the advantage that the dyed ground produced by mordanting and dyeing can be preserved indefinitely and thus be discharged whenever required.—A. J. H.

Printing process. A. Dietz. G.P. 303,055, 5.10.13, and 322,609, 15.2.18.

The process is designed for use with a plate with a matt surface or with glass or porcelain rolls, treated only with a liquid containing glycerin and hydrochloric acid, to which colour may be added preparatory to the transfer of the original and to the application of the printer's ink. A little benzoic acid is added to the above liquid and alcohol is used in place of part of the glycerin, and formic acid in place of part of the hydrochloric acid. The benzoic acid keeps the reprint-plate clean and the addition of alcohol keeps the benzoic acid in solution and transfers it to the reprint-plate in the finest state of division. For example 16·25% of magnesium chloride and 2·25% of aluminium sulphate are dissolved in 30·25% of boiling water and after cooling 1·80% of pure hydrochloric acid, 3·60% of glacial acetic acid, 3·60% of formic acid, 1·35% of benzoic acid, 13·80% of glycerin, and 27·10% of 98% alcohol are added. The plates are prepared with this mixture and the original, written with an ink containing iron salts and ammonia, is lightly pressed on it and after a short time taken off again. The already visible impression is then treated with colour suitable for this class of work. Only the writing takes the colour, the remainder of the plate being unaffected. This process allows of the production of a large number of reprints of great accuracy without the fresh preparation of the plate after each copy. The main patent deals with the employment of printer's ink containing glycerin. If other inks, such as lithographic inks from coal tar dyes, are to be used a little glycol and if necessary a small quantity of a sodium salt such as sodium sulphate, sodium bicarbonate, or especially sodium benzoate, must be added. The glycol unites better with the colour than glycerin, and half the quantity is sufficient. The addition of the sodium salt causes the colour to be retained better by the negative.—H. C. R.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Lead chamber [sulphuric acid] process; Physico-chemical study of the ——. M. Forrer. Bull. Soc. Chim. Belg., 1922, 31, 254—293.

In order to investigate the reactions which take place in the lead chamber process and to determine the temperature coefficient, the apparatus used was such that the five chief gases present during the course of the reaction (sulphur dioxide, nitrogen peroxide, water vapour, oxygen, and nitrogen) were used in mixtures of known composition which could be varied at will. These mixtures were passed at a known rate into a chamber of known dimensions at a definite temperature, each of these factors being susceptible of variation. Numerous experiments were carried out and in each case the quantity of acid produced was measured and the acid itself analysed. The author shows that formation of acid only takes place in presence of a liquid phase, so that the time of formation is decreased and the yield increased by the preliminary addition of a small quantity of liquid in order to start with a heterogeneous system. This liquid should be sulphuric acid itself, as water evaporates and the presence of water vapour is not sufficient to bring about formation of acid. Under certain conditions the acid itself disappears, this being due to reversal of the reaction; these conditions, however, are different from those which obtain in industry. For low concentrations of gas there exists an optimum rate of intake for water; this gives the highest yield and, at the same time, the most concentrated acid. As the gas concentration increases this optimum rate shifts in the direction of diminution of water supply. When the concentration of the liquid phase is constant, the relation between the velocity of the reaction and the concentration of the gaseous phase is much less complex than in the case when the liquid phase is of varying concentration. The rate of supply of sulphur dioxide does not appear to influence the reaction velocity; on the other hand, nitrogen peroxide and water both exert considerable influence. The results point to the formation of an intermediate substance of which water is a constituent but which is decomposed by an excess of water. Under industrial conditions, *i.e.*, in the production of chamber acid, the rate of intake of water is exactly that which corresponds to the optimum reaction velocity.—H. J. E.

Sulphuric acid; [Nitre losses in] the manufacture of —— in tower systems. S. Micewicz. Chem.-Zeit., 1922, **46**, 847.

In a particular tower system in which the nitre consumption was normally 1·0—1·2% HNO_3 on monohydrate acid made, this figure occasionally rose without any evident reason to 2—3%, and even to 4·4%. It was noticed that at times of heavy nitre consumption the acid was cloudy, and a test of Glover acid at such a time showed that after driving off sulphur dioxide the acid still reduced iodine owing to the presence of arsenic, selenium, and ferrous salts. The losses of nitre were therefore attributed to reduction to nitrous oxide or nitrogen by arsenious acid in the towers of the "inner ring," the arsenious acid being regenerated by the action of sulphur dioxide in the Glover towers. The settling out of arsenic accumulations is suggested as a remedy.—C. I.

Boric acid; Determination of ——. W. Strecker and E. Kannappel. Z. anal. Chem., 1922, **61**, 378—397.

The material in which boric acid is to be determined is distilled with phosphoric acid and methyl alcohol, a current of air saturated with methyl alcohol being passed through the apparatus during the distillation; the distillate is collected in a receiver containing sodium hydroxide solution. When all the methyl borate has been collected in the receiver, the contents of the latter are boiled to expel methyl alcohol and to saponify the ester, the solution is then treated with a very slight excess of hydrochloric acid (red coloration towards methyl orange), boiled to expel carbon dioxide, mannitol is added in the proportion of 1 g. for each 10 c.c. of solution, and the mixture is titrated with *N*/10 barium hydroxide solution, using α-naphtholphthalein as indicator.—W. P. S.

Borax; Alternate precipitation of borax and ammonium chloride in the industrial preparation of —— by the double decomposition, $(NH_4)_2B_4O_7+2NaCl \rightleftarrows Na_2B_4O_7+2NH_4Cl$. U. Sborgi and C. Franco. Giorn. Chim. Ind. Appl., 1922, **4**, 245—249.

The results of further investigations of this reaction (J., 1921, 693 A) render it possible to increase the chemical yield of the process to 100% for all the substances used. For the same volume of the original mixture employed, the output of borax per cycle of operations is diminished by 48%, that is, the absolute production of borax is lowered to this extent. Thus, using the new modification, only 489 g. of $Na_2B_4O_7,10H_2O$, is obtained from the volume previously yielding 941 g., but 136·72 g. NH_4Cl is also obtained. The number of operations is not notably increased, since the mother liquor from the borax, if the ammonium chloride is not crystallised from it, would be treated for the recovery of the ammonia. The whole process is as follows. The composition of the initial mixture (I) reacting at 10° C. and the amount of crystallised borax it yields, as well as the composition of the mother liquor (I) remaining after filtration are as before (*loc. cit.*). Mother liquor I is concentrated 2·35 times, yielding a distillate (I) containing NH_3 5·96 g. and H_2O 559·24 g., and a residual solution. The latter, crystallised at 37° C., deposits 136·72 g. NH_4Cl and gives a mother liquor (II) of the composition: NaCl 104·82 g., NH_4Cl 126·86 g., H_3BO_3 43·42 g., and H_2O 425 g. To this mother liquor II are added distillate I and also NaCl 149·48 g., H_3BO_3 316·58 g., NH_3 43·56 g., and H_2O 115·76 g. The resulting mixture (II) of the composition: NaCl 254·30 g., H_3BO_3 360·70 g., NH_3 49·52 g., NH_4Cl 126·86 g., and H_2O 1100 g., is stirred for some hours at 10° C. In this way 489 g. of crystallised borax is precipitated, and there remains mother liquor I, with which the cycle is recommenced. This second batch of precipitated borax and also the ammonium chloride are impure and are washed, the accumulated wash waters being mixed and concentrated, giving a distillate, which is added to distillate I, ammonium chloride, and mother liquor, which is added in suitable amount to mother liquor II.—T. H. P.

Fluorides; Detection and estimation of ——. N. K. Smitt. Bull. Bur. Bio-Tech., 1922, No. 6, 176—178.

Greeff's volumetric method for the estimation of fluorides (J., 1913, 992) may be simplified as follows. To 5 or 10 c.c. of the neutral fluoride solution are added 5 c.c. of 10% ammonium thiocyanate solution and 25 c.c. of alcohol, the mixture being titrated directly with alcoholic ferric chloride solution which has been standardised against pure potassium fluoride under exactly similar conditions. It is essential that the solution be neutral and that the same volumes of indicator and solution be always used, as the presence of more water destroys the final colour and this gives high results. The concentration of the ferric chloride is conveniently 1—3% according to the strength of the fluoride solution to be tested. Sodium salicylate may be used as indicator instead of the thiocyanate. For the detection of a fluoride in a solution, the latter is neutralised and treated with a little thiocyanate solution and then with ferric chloride solution, drop by drop. In the absence of interfering substances, the presence of fluoride is indicated by the rapid disappearance of the colour of the ferric thiocyanate. Insoluble fluorides, such as calcium fluoride, may be detected in this way, if the substance is ground vigorously in a mortar with small quantities of thiocyanate and ferric chloride solutions. Traces of fluoride (0·005—0·0005%) in neutral aqueous solution may be estimated as follows. To 10 c.c. of the solution are added 0·5 c.c. of 10% ammonium thiocyanate solution and next 0·1% ferric chloride solution, drop by drop, from a micro-burette until a pale orange colour appears. To six test-tubes are then added such different quantities of a dilute standard potassium fluoride solution that when the volumes are made up to 10 c.c. and exactly the same amounts of thiocyanate and ferric chloride solution added to each, the colour observed in the unknown solution falls within this standard range; if necessary, intermediate standards are prepared in order to obtain a more exact matching. If a control test is carried out at the same time, the fluoride in 10 c.c. of 0·0001% potassium fluoride solution is detectable.—T. H. P.

Ferrous hydroxide; Reducing action of ——. [Determination of nitrites and nitrates.] S. Miyamoto. Nippon Kwagaku Kwai Shi (J. Chem. Soc. Japan), 1922, 43, 397—438.

Nitrites and nitrates may be estimated as ammonia after reducing with ferrous hydroxide. The nitrite (0·1—0·3 g.) is boiled with ferrous sulphate (15 g.) and saturated solution of caustic alkali (200 c.c.) and the evolved ammonia is absorbed by sulphuric acid. Nitrates are more difficult to reduce, and it is necessary to boil the mixture under a reflux condenser for 3—3·5 hrs., during which hydrogen, nitrogen or air is introduced into the flask. Nitrobenzene is reduced to aniline at the ordinary temperature by ferrous hydroxide.—K. K.

Sodium oxalate; Transformation of sodium formate into ——. C. Matignon and G. Marchal. Bull. Soc. Chim., 1922, 31, 789—796.

The yield of sodium oxalate obtained on heating pure sodium formate to 440° C. varies from 48 to 50%. This may be increased to 85% by adding as catalyst 4% of caustic soda to the formate, but addition of greater quantities of caustic soda results in decreased yield. Commercial formate, which normally contains about 1·3% of caustic soda as impurity, gives a yield of about 70%; addition of a further 2% of soda increases this to 83%. The oxalate is easily separated from the resulting mixture by treatment with a small quantity of cold water, which dissolves carbonate and unchanged formate whilst only a small percentage of oxalate passes into solution. The oxalate is then crystallised from hot water.—H. J. E.

Carbon; Colloidal solutions of —— in water. P. C. L. Thorne. Kolloid-Zeits., 1922, 31, 119—132.

A stable carbon sol may be prepared by the electrolysis of a solution of ammonia for 6 hrs. between carbon electrodes with an anode current density of 0·6—1·2 amp. per sq. cm. and a voltage of 220. After filtering, the solution had an ammonia concentration of 0·145*N* and gave a solid residue of 0·034 g. per 100 c.c. The residue is insoluble in water but forms a colloidal solution again in presence of a trace of ammonia; the excess of ammonia may be removed by boiling and the sol is then more stable than the original sol, which on dialysis is flocculated when the ammonia concentration falls to 0·039*N*. The ammonia-free sol is deep black in layers greater than 1 cm. thick and brown in thinner layers and is made up of particles of about the same size as those of metallic sols. The number of millimols of electrolytes necessary to coagulate 1000 c.c. of the dialysed sol is: hydrochloric acid, 60; sodium hydroxide, 290; ammonium hydroxide, >9000; sodium chloride, 450; barium chloride 0·5; and aluminium chloride, 0·3. The composition of the dry residue is C 66·61%, H 1·99%, O 15·25%, and incombustible residue 16·15%.—J. F. S.

Carbon; Behaviour of —— at high temperatures. F. Sauerwald. Z. Elektrochem., 1922, 28, 183—185. E. Ryschkewitsch. *Ibid.*, 185—186.

On heating rectangular rods of pure graphite in the author's resistance furnace (*cf.* p. 823 A) to the temperature of the positive crater of the arc in an atmosphere of hydrogen, the rod opened out in the middle and eventually broke, the broken ends having a forked appearance and being quite smooth nside but covered with small globules of apparently fused material on the outside. The rod itself contained 0·08% of ash, while the globules contained 78%. The author suggests that the impurities in the carbon had distilled from the inner hot zone and condensed on the outer cooler zone, lowering its melting point and causing partial fusion of a carbide-graphite mixture, while the cause of the rod breaking was the development of a high pressure of carbon vapour inside. If the temperature is kept near that of the arc for a longer period the carbide in the globules volatilises, leaving nearly pure graphite, and the author suggests that this is an explanation of Ryschkewitsch's production of drops of apparently fused graphite (J., 1921, 178 A, 810 A). Ryschkewitsch replies to the above by pointing out that his conditions as regards atmosphere and current density were different from the above and that in his case the whole cross-section of the rods had apparently fused and was of different hardness.—A. R. P.

Aluminium. Clennell. *See* XXIII.

Ferrocyanides. Müller and Lauterbach. *See* XXIII.

PATENTS.

Nitric acid; Process of fixing synthetical ——. M. Buchner. U.S.P. 1,427,441, 29.8.22. Appl., 6.4.21.

Synthetic nitric acid is treated with a sulphide of a metal of which the hydroxide is alkaline.
—L. A. C.

Acids; Process for concentrating volatile ——. C. Uebel. G.P. (A) 306,412, 12.2.16, and (B) 307,044, 29.8.16.

(A) In the concentration of volatile acids by means of liquid or fused dehydrating agents, the concentrator or evaporator is divided into compartments which communicate at the bottom by openings in the partitions and at the top by siphon overflows, and circulation of the contents is brought about by the introduction of weak acid and by the temperature and density differences of the contents in such a way that the entering weak acid meets the hottest and most dehydrated liquid. The vapour space in the evaporator is divided into compartments corresponding with the divisions of the liquid space in order to allow of separate removal and condensation of the vapours evolved. (B) The process is carried out under reduced pressure in apparatus arranged so that the chamber from which the concentrated acid vapour is withdrawn is under higher pressure than that in which dehydration of the weak acid is proceeding.—A. C.

Base-exchanging bodies; Preparation of artificial ——. American Zeolite Corp., Assees. of O. W. Willcox. E.P. 159,196, 18.2.21. Conv., 19.2.20.

A dilute solution of sodium silicate is added to a dilute solution of aluminium sulphate (or salts of other amphoteric metals, such as iron, tin, manganese, lead and zinc). The composition of the precipitate varies with the amount of sodium silicate added. At first the composition of the precipitate approximates to $15SiO_2,2Al_2O_3,9H_2O$; when the solution becomes neutral to phenolphthalein (methyl orange is not a satisfactory indicator) the precipitate approximates to $24SiO_2,3Al_2O_3,Na_2O,12H_2O$. Further addition of sodium silicate enriches the precipitate in silica and sodium oxide; when 40% excess sodium silicate has been added, the composition of the precipitate is $12SiO_2,Al_2O_3,Na_2O,6H_2O$. Ultimately a point is reached beyond which any additional amount of sodium silicate is found undiminished in the mother liquor. At this point the composition of the precipitate is approximately $19SiO_2,Al_2O_3,2Na_2O,7H_2O$. The product may be varied by using a mixture of two or more metal sulphates or a mixture of two or more alkali silicates. The tendency of certain metal sulphates, such as ferric sulphate, to hydrolyse in weak solution is prevented by the addition of alkali sulphates or chlorides, or by the addition of sufficient acid to keep the hydroxide in solution. The precipitate is collected, washed, freed from excess of water by a blast of air, dried in an oven at 60°—100° C., and plunged into water, which causes it to break up into granules of suitable size. Considerable increase in the density and hardness of the product is brought about by the addition of a neutral alkali salt (*e.g.*, sodium sulphate), say 5 pts. of the neutral salt to 1 pt. of the base-exchanging substance. (*Cf.* J., 1917, 1047; 1918, 415 A.)—J. B. F.

[*Silica*] *gels* [*; Preparation of —— impregnated with metallic oxides*]. W. A. Patrick. E.P. 159,508, 26.2.21. Conv., 28.2.20.

A hard highly porous silica gel, stable up to 700° C., prepared as in E.P. 136,543 (*cf.* U.S.P. 1,297,724; J., 1919, 363 A), may be obtained impregnated with a metallic oxide by replacing the hydrochloric acid by a chloride which is readily hydrolysed. For example 100 c.c. of 5·2% ferric chloride solution is mixed with 200 c.c. of sodium silicate solution containing 1·0% Na_2O. After the mixture has set the gel may be broken up and washed free from chlorides without loss of iron. The impregnated ferric oxide may be reduced to iron by the action of hydrogen. Owing to the fine porous structure of such a gel it forms a suitable vehicle for metallic or metallic oxide catalysts.—C. I.

Sulphates [*sodium sulphate*]*; Process and apparatus for the continuous production of ——.* Soc. Anon. de Prod. Chim. Etabl. Maletra. E.P. 163,706, 19.5.21. Conv., 25.5.20.

Sodium chloride is first converted quantitatively into the acid sulphate, the necessary sodium chloride for the formation of the normal sulphate is then added and is so intimately mixed that the particles of sodium chloride become coated with the acid sulphate. The mixture is passed to a calciner for conversion into the normal sulphate. The process is continuous and is automatically controlled, and the three operations are carried out in a single apparatus.—J. B. F.

Aluminium and potassium chlorides; Method of separation of —— in mixed solutions obtained in the treatment of leucite. G. A. Blanc. E.P. 176,770, 15.2.22. Conv., 7.3.21.

The hot solution obtained by the treatment of leucite with hydrochloric acid is cooled, to separate potassium chloride. The mother liquor is then saturated with gaseous hydrogen chloride which causes the complete separation of crystalline aluminium chloride. The residual liquor can then be returned to the process.—C. I.

Aluminium sulphate for paper making; Process for making ——. M. Müller. G.P. 352,289, 11.8.17.

The aluminium sulphate is obtained in the wet way by acting on minerals containing alumina with sulphuric acid or alkali bisulphates, especially sodium bisulphate. The liquid reaction mixture is neutralised with magnesium hydroxide or carbonate or with minerals containing these compounds in one operation and the liquid obtained used directly as a precipitating agent in the sizing of paper. Alternatively the neutralising may be carried out with suitable alkaline-earth or aluminium compounds, such as soluble aluminium hydroxide in conjunction with magnesium compounds. The solidification and drying of the mass may be prevented by adding water and the finished product immediately used in the liquid state for sizing paper, clarifying water, etc.—H. C. R.

Hypochlorites and chlorates; Process for the production of —— and apparatus therefor. M. Wilderman. E.P. 183,671, 16.6.21.

The slow absorption of chlorine in milk of lime can only be accelerated by increasing the surface of contact between the liquid and gas. This is effected by employing chlorination towers filled with glass balls strung on wire coated with chlorine-resisting ebonite (F.P. 395,101 and addition thereto; J., 1909, 319; 1910, 641). The blocking of such apparatus by the settling out of lime is prevented by the addition of the latter in small quantities at a time to mixing vessels at the base of the towers, the initial liquor containing 5% of calcium hydroxide. The temperature of the towers is maintained at 60°—70° C., just below the point at which calcium chlorate begins to decompose. By this means the final liquor is brought (after filter-pressing) in a reasonable time to 60°—64° Tw. (sp. gr. 1·3—1·32). Such a solution is decomposed, still at 60°—70° C., with 2% excess of potassium chloride, yielding a solution which deposits the bulk of its potassium chlorate on ordinary crystallisation and a further pure crop on cooling to −20° C. An efficiency of 90—92% is obtained as against 74% in existing processes and all evaporation of chlorate mother-liquors is avoided. The principle can also be applied to the manufacture of high strength calcium hypochlorite solution.—C. I.

Copper sulphate; Process of, and apparatus for crystallising ——. J. M. Dossett. E.P. 184,527, 31.3.21.

Copper sulphate is obtained in very small crystals ("snow" or "sand" sulphate) by rapidly cooling the liquor in a vessel having a smooth surface. The walls of the container are preferably made of thin copper or enamelled metal and the cooling surface is increased by providing one or more slightly inclined tubes inside the vessel. The container is enclosed at the sides and bottom in a jacket through which cold water circulates, and the copper sulphate solution is kept in agitation by means of compressed air, or a stirrer.—H. R. D.

Electrolytic decomposition of alkali salts [*employing mercury cathodes*]*; Operation of processes and cells for ——.* M. Wilderman. E.P. 184,938, 16.6.21.

In cells for the electrolysis of solutions of alkali salts, *e.g.*, sodium chloride, employing mercury cathodes, as in E.P. 9803 of 1902 (J., 1903, 703), various means are provided for working with high current densities, without the oxidation of the mercury and without the formation of solid amalgam in the cells.—J. S. G. T.

Ammonia; Apparatus for catalytic synthesis of ——. L. Casale and R. Leprestre. E.P. 185,179, 24.5.21.

See U.S.P. 1,408,987 of 1922; J., 1922, 294 A. One or more additional partitions may be provided in the space between the outermost and middle tubes, so that the reacting gases take a tortuous path before entering the innermost tube.

Titanium oxide; Process of producing crystalline ——. G. Carteret and M. Devaux. E.P. 185,374, 27.6.21.

Titanium chloride free from iron is precipitated as gelatinous oxide by an alkali or alkaline-earth oxide or carbonate, the oxide is dissolved in 25% sulphuric acid, and re-precipitated in the amorphous state by boiling in presence of hydrogen. The amorphous oxide is converted into the crystalline variety by calcining.—C. I.

Magnesium carbonate; Process for producing ——. C. Cramer, Assr. to Chem. Fabr. Griesheim-Elektron. U.S.P. 1,427,444, 29.8.22. Appl., 12.6.22.

Magnesium carbonates are produced by the interaction of ammonium carbonate and soluble magnesium salts, the mixture being kept agitated during the reaction.—H. R. D.

Zinc sulphate solutions; Purification of —— [from arsenic]. C. R. Kuzell and J. R. Marston. U.S.P. 1,427,826, 5.9.22. Appl., 15.8.21.

Zinc sulphate solution containing arsenic as impurity is acidified with sulphuric acid, treated with a metallic sulphide, and heated until the arsenic is precipitated as sulphide.—J. B. F.

Iron oxide and other products; Process for recovering —— from spent iron sludge. C. V. Bacon. U.S.P. 1,428,521, 12.9.22. Appl., 2.1.20.

Iron sludge, consisting essentially of iron oxide, is treated with sufficient sulphuric acid to convert it into a dry mixture containing mainly ferrous and ferric sulphates, and this is decomposed by heating, whereby sulphur compounds volatilise off, and iron oxide is recovered.—J. B. F.

Barium chloride; Method of producing ——. J. H. MacMahon, Assr. to The Mathieson Alkali Works. Inc. U.S.P. 1,428,646, 12.9.22. Appl., 20.8.20.

Finely ground barium carbonate is treated with a hot solution of ammonium chloride, the volatile by-products being removed as formed, by aspirating air through the solution.—J. B. F.

Calcium arsenate; Manufacture of ——. C. B. Dickey, Assr. to Pittsburgh Plate Glass Co. U.S.P. 1,428,946, 12.9.22. Appl., 7.8.20.

Calcium arsenate practically free from soluble arsenic compounds is prepared by treating a soluble arsenic compound with calcium hydroxide suspended in water containing 1—5% of salt.
—J. B. F.

Nitrogen; [Electric arc] furnace for oxidation of atmospheric ——. A. U. Avera. U.S.P. 1,429,013, 12.9.22. Appl., 26.3.21.

The furnace consists of a glass, porcelain, or quartz tube containing a hollow iron core through which the ingoing air passes and which forms one pole of a high-tension circuit, the other pole being the tube lining. The air is subjected to a high-tension static charge and to an arc discharge simultaneously. The furnace is placed in a bath of oil of high flash point provided with water cooling coil.—C. I.

Litharge; Process for making —— from molten lead. L. Kübler. G.P. 355,649, 16.11.20.

The lead is oxidised with a mixture of carbon monoxide with excess of air, to which, if necessary, superheated steam is added. The cast iron oxidation vessels are not subject to such heavy depreciation as in other processes.—H. C. R.

Liquid air; Process and apparatus for continuous rectification of ——. E. Barbet et Fils et Cie. E.P. 159,131, 11.2.21. Conv., 11.2.20.

In carrying out the process described in E.P. 131,321 (J., 1919, 766 A) the nitrogen compressor is operated at a higher pressure, viz., at 14 kg. per sq. cm., which is in excess of that necessary for the operation of the rectification apparatus. The portion of the compressed nitrogen remaining unliquefied is then subjected to adiabatic expansion, which effects a lowering of temperature, which in turn provides a reserve of cold units to make good loss of cold by the apparatus.—H. R. D.

Red phosphorus and arsenic; Method for the separation of a mixture of ——. W. Siegel, and J. Michael und Co. G.P. 356,809, 30.4.21.

The mixture, at an increased temperature, is exposed to the simultaneous action of water or steam, and air or oxygen, and from the resulting mixture of red phosphorus and arsenic trioxide the latter is removed by solution. The treatment may be effected in presence of oxygen carriers.—J. B. F.

Alkali metal monochromates; Process for transforming —— into bichromates or chromic acid. G. N. Vis. U.S.P. 1,429,001, 12.9.22. Appl., 10.7.19.

See E.P. 131,289 of 1919; J., 1920, 516 A.

Hydrogen; Process of preparing ——. J. C. Clancy, Assr. to The Nitrogen Corp. U.S.P. 1,425,578, 15.8.22. Appl., 14.5.20.

See E.P. 163,323 of 1921; J., 1922, 631 A.

Electric furnace for production of carbide. E.P. 185,136. *See* XI.

Electrolytic method and apparatus. U.S.P. 1,427,236. *See* XI.

VIII.—GLASS; CERAMICS.

Glass; Effect of manganese in —— melted under reduced pressure. E. N. Bunting. J. Amer. Ceram. Soc., 1922, **5**, 594—596.

The decolorising action of manganese is destroyed by melting and fining glass at 1400° C. under a pressure of 0·03 atm. The decolorising oxide, Mn_2O_3, is decomposed under these conditions into MnO and oxygen.—H. S. H.

Clays; Composition and microscopical structure of ——, their fusibility and behaviour at high temperatures. L. Bertrand and A. Lanquine. Céramique, 1922, **25**, I., 153—157. Chem. Zentr., 1922, **93**, IV., 489—490.

It is established by the determination of the alumina content and fusion points of 101 samples of clay that conclusions as to the refractory qualities cannot be drawn from the content of alumina. Although all clays containing more than 30% of alumina were refractory, some having as little as 8·15% had a fusion temperature of 1650° C. or higher. Four clays containing 16·6% to 21·85% of alumina melted between 1270° and 1120° C.
—H. C. R.

Flint and chalcedony; Products of the calcination of ——. E. W. Washburn and L. Navias. J. Amer. Ceram. Soc., 1922, **5**, 565—585.

The specific gravity at 0°, 25°, and 98° C., the index of refraction, the coefficient of thermal expansion up to 300°, the inversion temperature and volume change on inversion, and the X-ray spectra of quartz, tridymite, cristobalite, silica glass, and raw and calcined flint and chalcedony were obtained. A special vacuum pycnometer was used for determining the specific gravity. The immersed powder was subjected to a pressure of 1000 atm. without any appreciable change in the results obtained. The specific gravity of calcined chalcedony was raised 2% by fine grinding. The densities of raw flint and chalcedony were lower than, but close to, that of quartz, the difference being not greater than that which might arise from the presence of moisture and other impurities in the raw materials. The density of calcined flint was slightly lower than, but close to, that of tridymite. The density of the calcined chalcedony was distinctly lower than that of silica glass, the lightest known form of silica. The indices of refraction of raw flint and chalcedony were substantially the same, and while close to that of quartz were distinctly lower. The refractive index of calcined flint was close to that of cristobalite, while the refractive index of the calcined chalcedony was definitely lower than those of cristobalite and tridymite, but agreed very well with that of silica glass. As far as these two properties were concerned, the calcined chalcedony might be considered as a form of silica glass, while the calcined flints might be either cristobalite or tridymite. Both the calcined flint and the calcined chalcedony exhibited a typical $\alpha-\beta$ cristobalite inversion. X-ray crystal analysis showed that raw flint and raw chalcedony contained large quantities of quartz crystals, and that calcined flint and calcined chalcedony contained considerable quantities of cristobalite crystals, and no other crystals of any kind. It was concluded that flint and chalcedony consist of colloidal quartz. When calcined, the colloidal quartz crystals were, owing to the large surface they exposed, very rapidly transformed into cristobalite crystals. At the same time some of the smaller original colloidal quartz crystals probably "melt," and the silica glass produced immediately proceeds to crystallise slowly, with the formation of colloidal cristobalite crystals. Since there would be a gradual gradation of properties from those of isotropic silica glass to those of macro-crystalline cristobalite, the low index of refraction and low density of calcined chalcedony are explained.—H. S. H.

Vanadium in ceramic materials and products, and its action on the refractoriness, colour and tendency to form scum on pure kaolins and a typical brick clay; Occurrence of ——. O. Kallauner and I. Hruda. Sprechsaal, 1922, 55, 333—335, 345—349. Chem. Zentr., 1922, 93, IV., 701.

Vanadium pentoxide reduces the refractoriness of kaolin. The colouring power of vanadium pentoxide or potassium vanadate is only noticeable when 0·1% or more is present. Barium salts tend to prevent the formation of colour. Burning in a reducing atmosphere reduces the tendency to form vanadium scum, and the presence of calcium and barium compounds has a similar effect.—A. B. S.

Biscuit losses; Control of ——. I. E. Sproat. J. Amer. Ceram. Soc., 1922, 5, 588—593.

The chief factor in the control of the biscuit losses is the transverse strength of the body in the clay state. Biscuit losses decrease with every marked increase in transverse strength up to 300 lb. per sq. in., but if the transverse strength is further increased the body has poor working qualities. It is suggested that the best results are obtained with a body having a modulus of rupture of 280 lb. per sq. in. As much moisture as possible should be expelled from the ware before it is handled.
—H. S. H.

Ground coat enamels; Fish scaling of ——. B. T. Sweely. J. Amer. Ceram. Soc., 1922, 5, 618—622.

The first coat was dissolved with hydrochloric acid from the inside of an enamelled basin, and the corresponding area outside the basin was found to be badly fish-scaled. If the enamel were in compression, the removal of it from one side of the steel would throw the entire stress taken by the inner and outer coats upon one coat, and so exaggerate the tendency to fish-scale over the area from which the one coat of enamel was removed. No fish-scaling developed with a basin coated on the outside only when the same test was made, showing that the results could not be explained by hydrogen penetration. No fish-scaling was produced when the enamel had a greater coefficient of expansion than the steel, and so was in tension rather than compression.—H. S. H.

Glass; Production of optical —— almost free from striæ. J. Desenberg. G.P. (A) 300,095, 2.9.15, (B) 302,571, 15.9.15, (C) 303,263, 15.9.15, (D) 303,264, 22.12.15, (E) 303,993, 27.7.16, and (F) 306,308, 17.2.17.

(A) A finished melt, after thorough mixing to remove layers of different fluidity, is cooled rapidly until the viscosity of the mass is such that subsequent separation into layers forming striæ is retarded as much as possible. The process of melting may be continuous if the glass is removed from the furnace for chilling. (B) The glass, in such form that it has a large surface in relation to its mass, is cooled by gases, fluids, or solids so suddenly and to so low a temperature that it disintegrates, and the pieces formed are united into one at a temperature below that at which striæ are formed. (C) The fused, well-mixed glass is poured into moulds in which the surface is relatively large compared with the mass of glass, and cooled so rapidly that segregation is minimised. The strain produced by the rapid cooling is removed by heating and annealing. (D) A portion of the mixed finished glass is separated from the remainder with minimum disturbance and mixing, and this is cooled rapidly to below the temperature at which striæ form. For example, a bell-shaped receiver may be dipped just below the surface of the molten glass, and a cooling agent led into the bell to cool the glass below the temperature at which striæ form. The bell, with adhering solid or semi-solid glass, may then be removed and the cooling completed. (E) The mixing of the glass previous to the rapid cooling is effected by a current of gas, and this current may be continued during the cooling. (F) A separate agitator and cooler may be used, into which the molten glass overflows from a continuous working tank.—A. C.

Porcelain. British Thomson-Houston Co., Ltd. From General Electric Co. , E.P. 184,090, 27.9.21.

Beryl is substituted totally or in part for the felspar or silica usually employed in manufacturing porcelain, a suitable mixture for electric insulating material being clay 291 pts., silica 35 pts., felspar 144 pts., beryl 130 pts. A porcelain having the above composition and fired to cone 10 possesses greater dielectric and transverse strength, and resistance to impact and temperature change than ordinary first quality electrical porcelain.—H. S. H.

Kilns for firing pottery and other ware. C. F. Bailey. E.P. 184,716, 20.9.21.

Three kilns are built together, the outer kilns only being provided with fire-grates, and the flame from the fire-grates is divided, the greater part passing up, over, and down the outer kilns, and then uniting with the lesser part which has passed direct under the outer kilns; the flames from both outer kilns are also combined, and pass up, over, and down the middle kiln and finally up a side passage to the inner cone or conduit of the main chimney. Dampers are provided to regulate the proportions of gases going by the various routes, also a damper at the top of the chimney cone to conserve the heat while discharging and charging the kilns. For cooling the ware after firing, passages controlled by dampers are provided leading from the interior of each kiln to the annular space in the chimney formed by the outer wall and the inner cone.—B. M. V.

Kiln; Ring chamber —— for burning ceramic material, lime, dolomite, etc. H. Koppers. G.P. 352,043, 28.3.20. Addn. to 349,951 (J., 1922, 711 A).

The flues leading from the roof of one chamber to the sole of the next are provided with sand-seals near the sole of the chambers. Sand can be poured through a tube into a pit underneath the partition between the chambers, and opening at one side into a chamber. The side of the pit leading into the chamber has such a slope that the sand-seal can be broken by raking or shovelling out the sand as in the main patent.—H. C. R.

Clay, especially china clay; Refining ——. Plauson's (Parent Co.), Ltd. From H. Plauson. E.P. 184,880, 21.5.21.

China clay or other clay is refined by mixing it with nine times its weight of water, and subjecting it for a short time (5—10 mins.) to intensive high-speed mechanical disintegration, preferably in the colloid mill described in E.P. 155,836 (J., 1922, 357 A). A selective colloidising effect occurs, the silicic acid and other impurities not being affected, so that they rapidly settle out of the mixture when it is allowed to stand. The action is facilitated if a dispersion accelerator, such as potassium silicate, tannin or tanning agents, humus, or humic acid, saponin or other soap-like froth-forming substances, is present; 0·5—1% of potash water-glass appears to give the best result. The particles of refined clay show the Brownian movement under the ultra-microscope. They may be collected on an ultra-filter press or ultra-filter centrifuge (E.P. 155,834 and 181,023; J., 1922, 619 A), and the resulting paste may be dried direct or *in vacuo*.—A. B. S.

Clay bodies; Method of producing ——. G. W. Lapp. U.S.P. 1,424,924, 8.8.22. Appl., 27.8.19.

Elastic material for use in the production of ceramic ware is made by forming a slip, filter-pressing the slip, enclosing the filter-pressed cakes in a receptacle, exhausting the receptacle of air and other fluid and compressing the filter cakes into a compact mass while retaining the reduced pressure within the receptable.—H. S. H.

Artificial meerschaum; Method of producing ——. P. Deussing. E.P. 164,319, 25.5.21. Conv., 7.6.20.

See G.P. 334,749 of 1920; J., 1921, 625 A.

Ceramic articles; Production of ——. E. C. R. Marks. From Lava Crucible Co. E.P. 185,435, 8.3.21.

See U.S.P. 1,374,909–10 of 1921; J., 1921, 434 A.

Sheet glass; Method of and apparatus for drawing ——. *Sheet glass drawing apparatus.* W. J. Mellersh-Jackson. From The Libbey Owens Sheet Glass Co. E.P. 184,989–90, 28.7.21.

Bricks or such like; Method and means of utilising waste heat for effecting the drying of ——. C. F. Twigg. E.P. 184,540, 14.4.21.

IX.—BUILDING MATERIALS.

Cement; Thermochemical research on ——. R Nacken. Zement, 1922, **11**, 245—247, 257—258. Chem. Zentr., 1922, **93**, IV., 366—367.

The author deals with the drying of cement in rotary dryers at about 500° C., the expulsion of carbon dioxide at 900° C., incomplete burning between 1000°—1250° C., in which stage exothermic reactions occur, burning at 1250° C., and finally strongly burning at 1400° C. or higher. The development of heat in the burning of cement is low below the stage at which carbon dioxide is expelled. The heat of reaction begins to increase slowly at 930° and rises from 120 to 500 cals. per grm., then more slowly to 600 cals. per grm. The maximum is at about 950° C. Immediately the carbon dioxide is expelled, a vigorous reaction occurs, *i.e.*, the formation of calcium silicates and aluminates, this reaching a maximum at 960° C., after which equilibrium is very quickly reached. Different results obtained in technical practice are due to heterogeneity of the raw materials and the fact that some calcium carbonate has escaped burning until the end. It is calculated that the quantity of heat required to burn 1 kg. of clinker up to a temperature of 1400° C. is about 900 cals.—A. C.

Blast-furnace slags; Conversion of acid —— *into basic slags and cement by remelting.* R. Grün and C. Biehl. Stahl u. Eisen, 1922, **42**, 1158—1167.

Portland cement can be produced from acid blast-furnace slag by the addition to the fluid slag of those oxides (lime and alumina) which are lacking in comparison with Portland cement. It is advisable to add alumina first and lime later. The process is, however, difficult to carry out in consequence of the high temperatures necessary. With increasing lime content the molten slag is only kept fluid with difficulty, stoppages are frequent, and the cost of working is high. The production of blast-furnace slag cement is however, practicable. The transformation of poorly hydraulic German slags into products suitable for this purpose requires relatively little heat consumption, the high temperatures necessary for making Portland cement are not necessary, and the troublesome formation of carbides is avoided. From these enriched slags a good blast-furnace slag cement may be milled which is equally as good as Portland cement. The enrichment of blast-furnace slag with lime alone is impracticable even with the most modern furnace construction. Alumina should be added before or with the lime to keep down the melting point. By this means a large enrichment in lime is possible, and a final product is obtained capable of being finely granulated and which has the latent hydraulic properties desired for blast-furnace slag cement manufacture. The addition of lime in quantity equal to that in Portland cement is not necessary. The lime content can be limited to 50%, by which means a blast-furnace slag may be made similar to basic German foundry slags and suitable for the production of blast-furnace slag cement.—T. H. Bu.

Concrete in sea-water; Tests of ——. L. C. Wason. Proc. Amer. Soc. Civil Eng., 1922, **48**, 1597—1604.

Test specimens of reinforced concrete (of different proportions and different amounts of mixing water) were immersed for 13½ years in sea-water under stringent tidal, abrasive and temperature conditions, portions of the specimens being permanently above high water mark and portions below low water mark. Test blocks were cut from the upper and lower portions of four poor specimens, and crushing tests made to the point of failure. The dry upper portions were found to have a consistent strength of 92% of that of the wet lower ones. From these tests and from others described, the mechanical action of the elements appears more important than the chemical, while dry-casting of concrete work and the quantity of mixing water, are influencing factors. Steel is adequately protected from corrosion, and a rich concrete made of good quality normal cement (or one low in alumina) mixed with 9—10% of water and dry-placed with careful spading gives durability below low and above high tides, enhanced if a protective coating is laid between tidal limits should abrasion be great.
—J. B. P.

Patents.

Wood; Impregnation of ——. Soc. de Recherches et de Perfectionnements Industriels. E.P. 168,045, 19.7.21. Conv., 20.8.20.

Wood is impregnated with crude or purified xylenol (from coal tar), either alone or mixed with other substances, and suspended or emulsified in an inert medium such as water; soap, preferably sodium resinate, is added to stabilise the emulsion.
—A. B. S.

Bituminous compositions; Manufacture of —— suitable for building or for forming road or like surfaces. A. R. Tabary. E.P. 183,914, 28.4.21.

A product for coating or paving roads etc. and for manufacturing building materials is made by adding fine sand or crushed hard material to a mixture of mineral or vegetable pitch, clay, limestone, and asphalt. The product may be incorporated with the ordinary materials used in making a metalled road or superficially distributed with tar, or cast in the joints of stone or wood paved roads.
—H. S. H.

Kilns; Vertical gas-fired —— for burning limestone or the like. C. F. Priest. E.P. 184,057, 3.8.21.

The gas belt of a vertical gas-fired kiln is provided with hoppered cleaning chambers placed between the belt and the gas ports, the chambers being provided with manholes, gas-inlet and control valve, and dust and tar collecting and releasing means. A hopper is provided for discharging the finished lime and has one or more adjustable air inlets. A large storage chamber is placed above and distinct from the preheating zone with a hopper between the chamber and the preheating zone. The products of combustion are passed through the upper part of the kiln to dry and preheat the limestone without passing through the storage chamber of the kiln. The air inlets are provided with protection plates in order to prevent choking.—H. S. H.

Rotary [cement] kilns [; Heat insulation for ——]. O. Faber and H. V. A. Briscoe. E.P. 185,327, 5.9.21.

Lagging made up in the form of sectional plates of non-conducting material is applied to the outside of the steel shell of a rotary cement kiln and is fixed by set screws (or other means) made of fusible metal, melting at say 600° C., so that in the event of the lagging being too effective and causing the steel plates to overheat, the screws will fuse and the lagging drop off and thus call attention to the danger and also to a certain extent automatically cure the overheating. The insulation may be made thicker and more effective at the cooler end of the kiln.—B. M. V.

Roofing material or tile. Durato Asbestos Flooring Co., Ltd., and A. Z. Nemeth. E.P. 184,910, 31.5.21.

Slabs or tiles are made from sawdust, saturated with magnesium chloride solution of sp. gr. 1·07 (10° B.), and then mixed with 1 pt. of magnesite and 3—4 pts. (by vol.) of soapstone (the soapstone being about one-tenth of the whole mass), and the whole mixed with a further quantity of magnesium chloride solution of sp. gr. 1·12 (15° B.), so as to form a homogeneous paste. The faces of the tile are afterwards coated with a waterproofing material.—A. B. S.

Building material; Process for the preparation of a raw material from peat for making a ——. E. Dyckerhoff. G.P. 356,334, 6.5.16.

Peat is treated, without drying, with a chloride solution, such as magnesium chloride mother liquors from working up carnallite, the resulting mass is mixed with cement or the like, and the mixture rolled into plates or shaped into bricks.—A. R. P.

Products from wood. G.P. 354,865. *See* IIb.

Kilns for burning lime etc. G.P. 352,043. *See* VIII.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Wrought iron; Direct smelting of —— from ore by Basset's process. I. Móscicki. Przemysl Chem., 1922, **6**, 73—81. Chem. Zentr., 1922, **93**, IV., 372.

Wüst's objections (J., 1922, 59 a) are regarded as unfounded in view of the fact that he did not take the dissociation of carbon dioxide into account in calculating the temperature of combustion. The temperature of 2560° C. quoted by Wüst for open-hearth furnaces should be only 2220°, which is only 25° C. above the value calculated for Basset's process. Further, with the rotary furnace a lower flame temperature than that required in the open-hearth furnace would suffice, and it may be accepted that combustion temperatures quite sufficient for smelting iron can be developed in Basset's furnace.
—A. C.

Iron; Sulphur in the metallurgy of ——. E. Bianchi. Giorn. Chim. Ind. Appl., 1922, **4**, 254—260.

Experiments were made at temperatures up to about 1000° C., in an apparatus comprising two tubular electric furnaces with resistance heating, one for the preliminary heating of the gas used or for the production of carbon monoxide and the other for the actual reaction to be studied. A small arc furnace with immersion electrode and arrangements for sampling the gases and for direct and spectroscopic observations was also employed. The more important results and conclusions arrived at are as follows:—Calcium chloride dissociates only in presence of oxygen or in a strongly oxidising medium; carbon dioxide has little action on it owing to the low temperature at which the chloride volatilises. Sulphides give up sulphur only in a strongly oxidising medium; in presence of carbon monoxide or dioxide they remain fixed or at most form stable metallic oxysulphides. Sulphates are dissociated in presence of oxygen giving sulphur trioxide and dioxide and oxygen, and are reduced to sulphide in a reducing medium containing carbon monoxide. The presence of lime has no appreciable effect on compounds of iron, sulphur, carbon, and oxygen. Consideration of these and of other known reactions in which a metal, sulphur, oxygen, chlorine, and carbon take part shows that the dissociation pressures of sulphur united to fixed bases are little inferior to those of oxygen. When heated these sulphides or oxides may be desulphurised or deoxidised, but the temperatures required at the ordinary pressure are so high as to be unattainable by ordinary means; an intermediate reaction thus becomes necessary. Thus, in a bath of sulphurised iron, the sulphur may be eliminated as sulphur dioxide, which is not dissociated at 1300° C., provided that the quantity of oxygen dissolved in the bath is in excess of the amount necessary to oxidise the carbon, phosphorus, manganese, and silicon; if there is a deficit of oxygen and an excess of carbon, a fixed oxysulphide, undissociable at the temperature of the molten bath, is formed. The pressures both of the chlorine in chlorides and of the vapours of the chlorides are generally so low that, in contact with the bath, these compounds are volatilised or decomposed before they are able to react with the fused metal. The bases contained in the slag are not sufficiently active desulphurising agents to have any practical effect, and the only reagents known to act in this way are the oxygen during the oxidising period of the refining, and the manganese, more particularly during the reducing period. It is possible that calcium and magnesium may be desulphurants even superior in this respect to manganese, but no practical proofs of this are yet available.—T. H. P.

Nickel steel and chromium steel; "Characteristic curves" of ——. H. Jungbluth. Stahl u. Eisen, 1922, 42, 1392—1396.

In the experiments of Portevin and Chevenard (J., 1921, 698 A) on a nickel-chrome steel soft quenchings (overhardening) were not obtained, but the possibility of obtaining them was indicated by the fact that the characteristic curves did not break off at the abscissæ, but bent and turned back into the region of soft quenchings, *i.e.*, the austenitic region, where the Brinell hardness is lower. To confirm this a nickel steel containing 0·5% C and 5·0% Ni, and a chrome steel containing 1·6% C and 1·6% Cr was quenched from temperatures varying from 750° to 1150° C. at varying velocities, four in the case of the nickel steel and seven with the chromium steel, the speeds varying from that of a water quenching to that of furnace cooling. A series of curves was plotted, all with quenching temperatures as abscissæ and with time, Brinell hardness, or quenching velocity, as ordinates. The bending of the curves is clearly shown, also the limiting curves for minimum and maximum hardness. The curve of maximum hardness cuts the family of curves into two parts giving softness on either hand due in one case to ferrite-troostite, and in the other to austenite. This was confirmed by micro-examination, maximum hardness corresponding with pure martensite being obtained for a given cooling speed, whilst higher quenching temperatures gave softness with austenite and lower temperatures softness with ferrite-troostite. From these curves the thermal conditions necessary to attain any desired grade of hardness can be read off directly, also whether the structure obtained will be austenitic or sorbitic.—J. W. D.

Steels; Influence of velocity of solidification on double-carbide ——. P. Oberhoffer. Stahl u. Eisen, 1922, 42, 1240—1242.

To determine the effect of the velocity of solidification on the properties of a series of chromium steels, steels of similar composition were cast in iron chills or allowed to cool down in the crucible respectively. On primary etching the steels cooled in the crucible showed a dendritic structure, those cast in chills an extremely fine globular structure. On secondary etching with a concentrated solution of picric acid in alcohol containing a few drops of nitric acid, a typical steel containing 1·16% C and 6% Cr showed a fine network of carbide when cast in chill, and a large network when cooled in the crucible. On forging down from 45 mm. to 15 mm. square the carbide network was elongated in the direction of rolling. The steel cooled in the crucible showed the eutectic similar to ledeburite in typical form, but in the chill cast steel the characteristics of the eutectic were no longer visible, and the carbide was very uniformly distributed. Mechanical tests on the forged test pieces gave no clear indications except that the shock tests were consistently higher for the chill cast specimens.—T. H. Bu.

Antimonial gold ores of the Murchison Range; Application of flotation to the ——. H. R. Adam. J. Chem. Met. Soc. S. Afr., 1922, 23, 3—9.

A number of tests were carried out to determine whether a flotation treatment of the ore would remove the stibnite in the concentrate and allow a good recovery of gold from the tailings. In every case it was found that the concentrate contained a considerable proportion of the gold, so that further treatment, *e.g.*, by roasting or volatilising roasting, followed by cyaniding, was necessary. The tailings from flotation yielded about 50% of their gold to mercury, but practically none of the remainder could be extracted by cyanide. The best results were obtained by grinding the ore wet to pass a 150-mesh screen, followed by amalgamation and cyaniding of the amalgamation tailing, whereby 87% of the gold was extracted. The gold appears to be associated intimately with tetrahedrite, and only after very fine grinding can it be successfully dissolved from the ore; the application of flotation in the treatment of the ore would simply be in place of the usual cyaniding and as a superior method of concentration to gravity methods.—A. R. P.

Silver-plated work; Cause of red stains on ——. A. Jefferson. Inst. of Metals. Sept., 1922. [Advance copy.] 4 pages.

Nickel-silver discs were silver-plated in a single vat under identical conditions, and finished by widely varying processes. The results obtained, together with those of tests of the rouge-finishing and hand-polishing processes, showed that the indiscriminate application of rouge to an over-heated surface is responsible for the red stains sometimes observed on silver-plated work.—J. B. P.

Brasses; Hardness of the —— *and some experiments on its measurement by means of a strainless indentation.* F. W. Harris. Inst. of Metals, Sept., 1922. [Advance copy.] 27 pages.

The hardness-composition curve of the brasses after sand casting, chill casting, and chill casting followed by hot forging and annealing was determined using the Brinell machine. A slight maximum occurs in the middle of the *α*-phase and a small depression in the *β*-phase. In the range 65—54% Cu the hardness bears an almost linear relation to the percentage composition. It is shown that the relation between the hardness H and the applied load for 70:30 brass could be expressed by $H=P^x+K$, where for zero load $H=K=25·1$, which is the true hardness of the material. The same bar after being indented with the ball was annealed and the ball replaced in the impression under the same load. This was repeated till the area of impression remained constant, viz., after the tenth anneal, when the ball hardness was 20·9. The absolute hardness number of the brasses was then determined, using this method of strainless indentation. The curve agreed in general form with the ordinary one, but was somewhat less sinuous. The relation between the Brinell and absolute hardness numbers is shown to be linear above an initial area of indentation of 9 sq. mm., but the amount of strain is not directly proportional to the size of the indentation. The significance of the maxima and minima in the hardness curves is considered.—T. H. Bu.

Cast metals and alloys; New forms of apparatus for determining the linear shrinkage and for bottom-pouring of —— *accompanied by data on the shrinkage and hardness of cast copper-zinc alloys.* F. Johnson and W. G. Jones. Inst. of Metals, Sept., 1922. [Advance copy.] 28 pages.

In the bottom-pouring method described, the molten metal flows from a heated crucible into the mould and the rate of flow is controlled by a stopper operated by a lever. The apparatus facilitates control of primary temperature and rate of pouring, and the exclusion of dross, and formation of "zinc-fume" or the like is minimised. The shrinkage values of chill-cast copper-zinc alloys found by the authors were higher than those obtained for sand-cast bars by Turner and Murray (J., 1909, 1137), but the curve showing the relationship of shrinkage to composition was similar to that previously obtained, except that no minimum at 60% copper was found. The hardness numbers were determined by the Brinell and the Shore methods, both on the alloys as cast and after annealing, the annealing producing uniformity. The Brinell hardness-composition curve showed an increase of hardness over the range 100 to 88% copper, a constant hardness from 88 to 72%, with a slight fall to 63%, at which point a rapid increase set in with the appearance of the beta constituent, an increase which was maintained to 45% copper with the exception of a small dip between 53 and 50%. The changes of the scleroscopic hardness with composition were of a similar character, but less pronounced, whilst over the range 60 to 53% copper no increase of hardness was shown, indicating a very slight difference, scleroscopically, between the beta and alpha phases. Tests on annealed bars cold rolled showed that the hardening capacity of the alpha brasses increases rapidly with increase of zinc between 100 and 75% copper. Hardness determinations on rolled strips, annealed, confirmed in general the results obtained on the bars cast and annealed.—J. W. D.

Copper wires; X-ray examination of the inner structure of ——. *Strained metals. I.* A. Ono. Mem. Coll. Eng. Kyushu Imp. Univ., 1922, 2, 241—260.

X-ray interference figures of strained metals and of metals annealed after straining show that the crystal lattices form a fibrous structure in the strained state and that this rearrangement becomes more pronounced the greater the strain to which the metal has been subjected. The inclinations of several simple planes in the face-centred cubic lattice and the relative intensity of the rays reflected from them have been calculated, and it is shown that a group of these lattices with the trigonal axis in the longitudinal direction of the specimen gives rise to the pattern obtained in the experiment. It is suggested that the changes in the lattice arrangement of crystals afford a more natural explanation of the changes of properties that occur in metals that have been subjected to strain than does the assumption that an amorphous layer is formed at the slip planes of the grains. —A. R. P.

Aluminium-copper alloys; Copper-rich ——. D. Stockdale. Inst. Metals, Sept., 1922. [Advance copy.] 14 pages.

The equilibrium diagram of copper-aluminium alloys containing up to 20% Al has been investigated by taking cooling curves and by the micro-examination of quenched specimens. Aluminium lowers the freezing point of copper to an amount proportional to the concentration up to 3·5% Al, at which point there is a slight break in the liquidus, which then falls as a smooth curve to a minimum at 1031° C. and 8·3% Al, rises to a maximum again at 12·55% Al and 1047° C., corresponding to the formation of Cu_3Al, and falls away again without another break up to 20% Al. The solidus lies very close to the liquidus for all alloys containing less than 18% Al, the maximum freezing range of these alloys being about 10° C. The eutectic line at 1031° C. has been traced from 7·5 to 8·5% Al and a second eutectic line has been established at 1017° C. in alloys containing 16·5 to 18% Al. Between 10 and 14% Al the liquidus and solidus coincide and above 18% Al the existence of a eutectic line at 868° C. has been confirmed. The α solid solution of aluminium in copper contains 9·8% Al at 20° C. and only 7·4% at 1030° C. Solid alloys containing 10—16% Al show a change point, corresponding to the disappearance of the β phase, at 537° C., and a second slight arrest at 286° C., while those containing 14—16% Al have an additional arrest point at 774° C., corresponding to the disappearance of the γ phase.—A. R. P.

Alloys of aluminium with copper, magnesium, and silicon in the solid state; Constitution and age-hardening of ——. M. L. V. Gayler. Inst. of Metals, Sept., 1922. [Advance copy.] 32 pages.

The solubility of each of the compounds, magnesium silicide and aluminium cupride, in solid aluminium is affected by the presence of the other; both are practically insoluble at 250° C., and at 500° C. the solubility is greatly reduced. The age-hardening of alloys containing copper and magnesium silicide is greater than of those containing either constituent alone and is due to the difference in the solubilities of Al_2Cu and Mg_2Si in solid aluminium at high and low temperatures. Of the two constituents magnesium silicide plays the predominant part. If one constituent is fixed the maximum age-hardening is obtained when the second constituent is present to the maximum amount which can be held in solution at high temperatures. Alloys which had been age-hardened at room temperature were found on further heat treatment to soften slightly, but subsequently showed increased hardness and tensile strength and rapid decrease of percentage elongation. Derived differential heating curves of quenched alloys containing 0·81% Mg_2Si with 1·5, 3·7, and 8% Cu showed three critical points, the highest due to the precipitation of copper, and the second to that of magnesium silicide.—T. H. Bu.

Aluminium; Effects of over-heating and repeated melting on ——. W. Rosenhain and J. D. Grogan. Inst. of Metals, Sept., 1922. [Advance copy.] 11 pages.

Aluminium of the highest obtainable purity (99·65%) and another grade containing 0·77% Fe and 0·72% Si, were cast at 700°, 800°, 900°, and 1000° C. respectively, forged into ⅜-in. slabs and rolled to 0·1 in. thickness. Tensile tests on pieces cut from the annealed sheets showed no evidence of deterioration in quality. The macrostructures of the small ingots were similar, except for an increase in crystal size with higher casting temperature. The highest-grade aluminium was melted and a portion cast at 720° C., other portions being held for 1 hr. at 900°—1000° C. and 1000°—1100° C. respectively before casting. After rolling to 0·5 in. thickness, longitudinal and transverse test-pieces were taken from annealed sheets, but no deterioration was found due to the above treatments. The rôle supposed to be played by oxidation during the melting of aluminium is therefore considerably exaggerated. The two grades were remelted and re-rolled to 0·05 in. thickness ten times, but no systematic change in the properties of the metal was found except a slight increase in the ultimate stress. The results are in contradiction to the views current in the industry, and it is probable that the deterioration ascribed to re-melting under industrial conditions may be due to a slight progressive contamination with other metals.—T. H. Bu.

Aluminium utensils; Cleaning of ——. R. Seligman and P. Williams. Inst. Metals, Sept., 1922. [Advance copy.] 2 pages.

The solvent action of sodium carbonate solutions on aluminium may be entirely prevented by the addition of small amounts of sodium silicate to the solution; thus, a 5% solution of "soda crystals" containing 0·05% of water-glass is without visible action on aluminium at 75° C. Mixtures of sodium carbonate and silicate, containing 10—12% of the latter and sold under the trade names of "Carbosil," "Pearl Dust," and "Aquamol," remove all the grease from aluminium articles without attacking the metal if sufficient is used to precipitate all the lime in the water, *i.e.*, in solutions containing more than 0·5% of the mixture.—A. R. P.

White metals. A. H. Mundey, C. C. Bissett, and J. Cartland. Inst. of Metals, Sept., 1922. [Advance copy.] 25 pp.

ANTIFRICTION alloys and other white metals such as the various classes of printers' alloys, die-casting alloys, metals for chemical works castings, solders, etc. are considered from the point of view of the manufacturer and user. Their composition, mechanical and physical properties are given, and their constitution and microstructure dealt with only so far as the user and the maker are directly concerned. Nine typical bearing metals, chiefly of the tin and lead base varieties, are fully described together with their suitability for particular purposes. The principal value of these alloys is due to the way in which they maintain the oil film, the hard constituent standing up in slight relief to carry the load and the softer matrix forming channels for holding the oil. In the tin-base bearing metals the copper-tin mixed crystals solidify first and entangle the cubes of tin-antimony mixed crystals, thus ensuring their uniform distribution. The functions of tin-base and lead-base alloys are similar. In casting bearing metals the greatest care and skill must be exercised, as overheating causes the oxidation and segregation of the valuable constituents, whilst if the pouring temperature is too low the hardening constituents are left behind in the ladle owing to liquation.—J. W. D.

Uranium alloys [with nickel, iron, and aluminium]. P. A. Heller. Metall u. Erz, 1922, **19**, 397—399.

ALLOYS of uranium with nickel or iron may be produced on a comparatively large scale by fusing suitable mixtures of uranium oxide (U_3O_8) and nickel oxide with the requisite amount of carbon in a carbon crucible by means of an arc. The oxide-carbon mixture is first briquetted by means of tar and the briquettes are heated in a wind furnace to drive off volatile matter before reducing in the arc furnace. Alloys of uranium with nickel containing 67—70% U and 4·5—5·0% C and with iron containing 45% U and 6·5% C have been prepared by this method. Attemps to reduce the carbon content of the nickel alloys by fusing them in a magnesia-lined furnace and adding nickel oxide resulted in the production of an alloy containing less than 1% C but only 26% U, the remainder of the latter having been slagged by the magnesia. The production of aluminium-uranium alloys by the thermit method gives a very poor yield, but satisfactory results may be obtained by reducing a mixture of uranyl fluoride and uranium tetrafluoride (formed by adding U_3O_8 to hydrofluoric acid) by means of metallic calcium in the presence of aluminium, the operation being conducted in an iron bomb. By this method an alloy containing 62·8% U, 34·8% Al, 1·4% Ca, 0·5% C, and 0·25% Si was obtained.

—A. R. P.

Antimony-bismuth system. M. Cook. Inst. of Metals, Sept., 1922. [Advance copy.] 16 pages.

A COMPLETE equilibrium diagram of antimony-bismuth alloys is given for the first time, and several doubtful questions of structure are elucidated in a full microscopical and thermal examination. The freezing points of bismuth and antimony are 270·5° C. and 630·5° C. respectively. The liquidus is smooth and unbroken, and the solidus is horizontal at 270° C. up to 60% of antimony, after which it rises, at first gently, then steeply to the freezing point of antimony, the system being isomorphous but not eutectiferous despite the horizontal solidus. Microscopical examination of chill-cast and slowly cooled specimens (etched with ferric chloride and hydrochloric acid save near the antimony end where copper ammonium chloride was used) revealed dendritic duplex structures which were rendered homogeneous by prolonged annealing at 275° C. Twinning, ascribed to stresses set up by expansion on cooling, and two kinds of banded structures were noted in some of the crystals.

—J. B. P.

Non-ferrous metals used in locomotives; Effect of superheated steam on ——. H. Fowler. Inst. Metals, Sept., 1922. [Advance copy.] 4 pages.

THE most suitable alloy for piston tail rod bushes in locomotives to withstand the action of superheated steam at 340° C. is a phosphor-bronze containing 11% Sn, 1% P, and 88% Cu, while for the piston rod packing (the McNamee rings) an antimonial lead containing 30% Sb is more satisfactory than the usual 20% Sb alloy. Gun-metal, phosphor-bronze, and cast iron were found unsuitable for the by-pass valves which are not only subjected to high temperature but also to a good deal of shock. A complex nickel brass containing small percentages of tin, lead, aluminium, manganese, and iron was found satisfactory, but owing to its high cost was replaced by malleable iron or steel castings.

—A. R. P.

Intermetallic actions. The system thallium-arsenic. Q. A. Mansuri. Inst. of Metals, Sept., 1922. [Advance copy.] 14 pages.

THALLIUM and arsenic do not interact chemically, nor do they form mixed crystals. The equilibrium diagram of the system is a perfect case of the immiscibility type. The freezing point of thallium is depressed by increasing additions of arsenic until the eutectic point (8·01% As, about 215° C.) is reached. After this the freezing point gradually rises to 240° C. All alloys containing 13—40% As begin to freeze at 240° C., and are made up of two layers—an upper layer rich in arsenic and a lower layer rich in thallium. The melting point of alloys containing more than 55% As is higher than 600° C., at which temperature the vapour pressure of arsenic becomes higher than 339·1 mm., and therefore the alloys have to be prepared in evacuated, sealed, hard glass tubes.—J. W. D.

Intermetallic compounds; Question of the existence of —— in the gaseous state. A. Eucken and O. Neumann. Z. Elektrochem., 1922, **28**, 322—324.

DISTILLATION tests on sodium amalgam (Na_2Hg) at pressures between 5 and 10 mm. showed that at 500° C. no appreciable quantity of any mercury-sodium compound could exist, although the boiling point of the liquid, when it had reached the composition, NaHg, remained constant for a considerable time.—A. R. P.

Grain-size and diffusion [in metals]. J. H. Andrew and R. Higgins. Inst. of Metals, Sept., 1922. [Advance copy.] 10 pages.

THE relation between grain growth and diffusion was studied by casting γ-brass (60% Zn) on to a thick rod of pure copper. The composite specimen was sectioned and examined under the microscope. Annealing for 30 hrs. at 800° and 850° C. respectively was found sufficient to promote diffusion and rapid grain growth simultaneously. Annealing at 500° C. for 12 hrs. and at 550°—575° C. for 5 days caused a breakdown of the β-crystals into smaller units but did not alter the α-constituent so markedly. In explanation of the breakdown of grain size by diffusion it is suggested that whilst in the interior of grains the atoms assume the state of closest packing, at the boundaries the atoms touch only at one part of the circumference. Plastic deformation may displace the equilibrium of certain boundary atoms which upon reheating tend to revert to the condition of closest packing, and rows of atoms may be brought into line with unstrained atoms of adjacent crystals. This may result in the breaking up of a grain or its absorption by others. The atoms lying along the grain boundaries have a greater number of free valencies, and this explains the migration of a separating phase to the grain boundaries. If the suggestions advanced are justified, it is not necessary to assume any amorphous material at the grain boundaries.—T. H. Bu.

Eutectics; Structure of ——. F. L. Brady. Inst. Metals, Sept., 1922. [Advance copy.] 45 pages.

Metallic eutectics may be divided into four classes: globular, in which both metals are of fairly high surface tension, and the metal of higher surface tension is present in the smaller amount, *e.g.*, cadmium-tin, cadmium-lead, copper-silver, zinc-cadmium, and zinc-bismuth; lamellar, in which the two metals have nearly equal surface tensions and are present in nearly equal proportions by volume and so separate in continuous curvilinear or reticulated sheets or plates, *e.g.*, lead-tin; angular, in which at least one of the metals has a low surface tension or a high cohesion, when the alloy solidifies as a mass of crystalline contour or arrangement, *e.g.*, antimony-lead, lead-bismuth, tin-bismuth, cadmium-bismuth, silver-lead, silver-bismuth, gold-bismuth, aluminium-tin, copper-bismuth, and copper-lead; crystalline, in which both phases have low surface tensions, and, on cooling, form merely a mass of contiguous crystals of the two phases, *e.g.* antimony-copper antimonide and most non-metallic eutectics. The structure of all the above eutectics is discussed in detail with reference to photomicrographs to substantiate the classification suggested. The eutectic range in the copper-silver series was found to be from 71·6 to 72·3% Ag in the silver-rich alloys and from 71·2 to 71·8% Ag in the copper-rich alloys.—A. R. P.

Corrosive action; The nature of —— and the function of colloids in corrosion, with an appendix on terms used in colloid chemistry. Sixth Report to the Corrosion Research Committee of the Institute of Metals. G. D. Bengough and J. M. Stuart. Inst. Metals, Sept., 1922. [Advance copy.] 80 pages.

A general discussion of corrosion phenomena based on the study of several different metals is presented and an examination of the electrochemical theory of corrosion is made, which shows that it is satisfactory only under certain conditions, while many facts can only be explained by recognising the important rôle of colloids in corrosion phenomena. Corrosion may be produced by chemical means, when the reacting bodies are in contact, or by electrochemical means when they are spatially separated and the reacting substances are capable of ionisation. Facts which are difficult to explain on a purely electrochemical theory are as follows: certain depolarisers do not increase corrosion, but inhibit it; the conductivity of electrolytes is not directly connected with the amount of corrosion; even exceedingly pure metals are corroded by neutral salt solutions and by dilute acids, and in many cases the presence of ions of the corroded metal does not depress corrosion but actually increases it. Again, the order of corrodibility of metals in distilled water, salt solutions, and non-electrolytes is different from that of their electrochemical potentials and the effects of strain and impurity in setting up potential differences between various parts of the metal are very small. It is shown that the amount of corrosion in commercial metals is not proportional to the amount of impurity, and that the depolarising power of atmospheric oxygen at ordinary temperatures is practically negligible, the main function of oxygen in corrosion being to oxidise the metal directly. The following theory is developed to explain the part played by colloids in corrosion. When a metal is immersed in water it becomes negatively charged and sends positively charged ions into the water, at the same time becoming superficially oxidised, if dissolved oxygen is present. The hydroxide so formed takes up the positively charged ions and becomes a positively charged colloid, which diffuses away in part, allowing further oxidation and a new formation of film, which is not further attacked until that portion of diffused colloid first formed has been removed from the solution by precipitation on coming into contact with an electrolyte, the action of which neutralises its positive charge. In this way the metal is gradually coroded unless the conditions cause precipitation of the gel on the surface of the metal itself, thus forming a protective coating which stops further action. The authors conclude that no one "theory of corrosion" can be proposed to account for all the observed phenomena, and that the final condition of a corroded metal is the result of a series of complicated actions, of which the initial action is either chemical or electrochemical, but is not dependent solely or mainly on the hydrogen ion concentration, but on the specific nature of all the ions in solution as well as on the presence of undissociated substances of which oxygen is the most important. The chemical actions which take place may be either ionic, molecular, or colloidal, and all may be influenced by the presence of gels and by the physical changes which take place in these gels.—A. R. P.

[Lead sulphide ores;] Technical working of raw materials containing lead [such as complex ——] by conversion of the lead into tetrachloride. A. Nathansohn and F. Leyser. Z. Elektrochem., 1922, **28**, 310—313.

By passing a current of chlorine into a suspension in water of finely divided ore containing galena, blende, and copper pyrites until an excess is present, the sulphur is converted into sulphuric acid, the zinc and copper to chlorides, and the lead to chloroplumbic acid, a solution containing 8% of lead being readily obtained. After separating the gangue and unattacked ore and passing a current of air through the clear liquor, the bulk of the lead is re-precipitated as lead chloride or sulphate. Wulfenite may be dissolved in a similar manner, but not zinc-lead products containing the metals as such or as oxides unless there is a predominating amount of sulphide present. The author suggests that the method would be useful for working up zinc-lead ores which do not admit of separation by flotation or gravity processes.—A. R. P.

Aluminium. Clennell. *See* XXIII.

Patents.

Welding of cast iron; Electrical ——. La Soudure Autogene Française. E.P. 173,486, 28.11.21. Conv., 24.12.20.

An electrode of grey cast iron is employed in welding cast iron, and carbon is added during the welding operation. A convenient method of introducing the carbon in a regular manner is to coat the electrode with powdered charcoal or graphite together with a binding agent, or to use a hollow electrode packed with carbon.—C. A. K.

Ferrotungsten and ferromolybdenum; Manufacture of ——. J. M. Skelley, J. Merson, and Continuous Reaction Co., Ltd. E.P. 184,843, 23.4.21.

Ferrotungsten or ferromolybdenum is made, without the aid of aluminium, by the silico-thermic reduction of iron oxide and tungsten oxide or iron oxide and molybdenum oxide in the presence of an oxidising agent.—J. W. D.

Ferrous alloys; Manufacture of ——. H. A. Skelley, A. B. Smith, and Continuous Reaction Co., Ltd. E.P. 184,844, 23.4.21.

ALLOYS containing iron and chromium, such as stainless steel, high-speed steel, and rustless iron, are made by the silico-thermic reduction of iron oxide in the presence of an oxidising agent and the incorporation of chromium and other metal or metals with the iron produced.—J. W. D.

Ferro-molybdenum; Manufacture of carbon-free ——. W. L. Turner. E.P. 184,912, 1.6.21.

IN the alumino-thermic process for the manufacture of ferro-molybdenum from molybdenite or molybdenum sulphide, a quantity of pyrolusite or manganese dioxide and aluminium is added to the mixture of molybdenum sulphide, aluminium, and iron oxide. The elimination of the sulphur content of the molybdenum sulphide is assisted by the relatively high temperature produced by the interaction of the aluminium and manganese dioxide and by the high affinity of the manganese and manganese compounds for sulphur and sulphur compounds. The molten alloy is subsequently treated with a slag containing a desulphurising agent, *e.g.*, a mixture of equal parts of lime and fluorspar.—T. H. Bu.

Iron, steel and ferrous alloys; Cementation of ——. Cammell, Laird and Co., Ltd., J. M. Allan, A. P. Hague, and T. Middleton. E.P. 184,920, 7.6.21.

THE article to be carburised is immersed in a fused salt bath containing 70% or more of sodium carbonate which may be mixed with barium carbonate or other alkali or alkaline-earth carbonate up to 25% and/or up to 5% of sodium nitrite or other fusible nitrogen-yielding salts. The temperature of the bath is kept above the carbon change point of the material being treated. The article is made the cathode of an electric circuit, the current density being 0·5—2 amp. per sq. in. of cathode surface. The time taken to obtain a given depth of carbon penetration is from one-third to one-sixth of that required by the ordinary process. Articles it is required to soften may be decarburised by immersing in a bath which has recently been used for the cementation process.—T. H. Bu.

Steel; Production of basic ——. Usines Métallurgiques de la Basse-Loire (Soc. Anon.). E.P. 184,957, 2.7.21. Addn. to 163,693 (J., 1922, 714 A).

GREY pig iron is treated by a one-stage blowing process for the production of hard or semi-hard steels with a high carbon content and practically dephosphorised, additions of recarburising agents being dispensed with by regulating the quantities of pig iron introduced into the bath according to its carbon and phosphorus contents.—J. W. D.

Manganese steel; Heat treatment of ——. W. G. Nichols, Assr. to American Manganese Steel Co. U.S.P. 1,427,121, 29.8.22. Appl., 18.9.20.

THE maximum temperature during the heat treatment of manganese steel castings is not allowed to exceed the critical temperature for such castings. —C. A. K.

Ferro-alloys; Production of low-carbon ——. N. Petinot. U.S.P. 1,428,057, 5.9.22. Appl., 26.9.19.

FERRO-CHROME is mixed with a quantity of chromite ore containing oxygen in excess of that required to combine with the carbon of the alloy, and melted in an electric furnace with an acid lining. —T. H. Bu.

Steel and iron alloy. P. de Clamecy, Assr. to B.F. Sturtevant Co. U.S.P. 1,428,534, 12.9.22. Appl., 6.10.19.

AN iron alloy containing 1·25—6·0% Co, 0·5—6·0% Cr, 0·75—7·5% Ni, and 0·5—3·0% Si.—J. W. D.

Metallic electrolytic deposits; Process of obtaining —— *easily detachable from the cathode.* Soc. d'Electro-Chimie et d'Electro-Métallurgie. E.P. 165,082, 13.5.21. Conv., 18.6.20.

A CATHODE of cast iron or steel is coated with an easily detachable film of copper by electrolysis or by immersion in an acid solution of a copper salt, either with or without the addition of alcohol, and the resulting electrode is used for the electrolytic deposition of metals, the deposited metal being readily peeled off together with the copper coating. —A. R. P.

Argentiferous lead-zinc sulphide ores; Treatment of ——. F. E. Elmore, and The Chemical and Metallurgical Corp. E.P. 184,628, 8.6.21.

WHEN treated by the hot brine process, roasted ores give a more complete extraction of silver if hydrogen sulphide is removed from the hot liquor. The use of sulphur dioxide is preferred for this purpose. Lead and silver may be recovered from solution by known methods and the zinc residue may be treated with other solvents, *e.g.*, more strongly acid brine, for the further recovery of silver.—C. A. K.

Refining metals; Apparatus for ——. H. Harris. E.P. 184,639, 20.6.21.

METALS of low melting point (*e.g.*, lead) are refined by passing them through a suitable molten reagent. An apparatus for this purpose consists of a pump which delivers into the upper part of a heated melting pot, a metal stirring gear, and a motor. These parts are carried on a framework, which can be lowered into a metal melting pot. The reagent may be heated by passing part of the flue gases from the metal melter through a jacket surrounding the pot containing the reagent. —C. A. K.

Alloys; Metallic ——. F. H. Rogers. From Calorizing Corp. of America. E.P. 184,840, 19.4.21.

CASTINGS resistant to oxidation at a high temperature are made from an alloy of iron and 19·5% of aluminium, which has a higher tensile strength than any other alloy of these two metals. The grain may be refined by the addition of 1 to 5% of titanium or of other elements. The alloying process is carried out in a neutral atmosphere, and to prevent oxidation the mould is filled with carbon dioxide, a blast of which is also directed on the stream of molten metal.—T. H. Bu.

Titanium ores containing iron; Treating ——. G. Carteret and M. Devaux. E.P. 184,948, 27.6.21.

TITANIUM ore is heated in a reducing atmosphere, and is then treated with successive currents of chlorine gas passed in opposite directions and at different temperatures, viz., 350° and 550°—600° C. respectively, to volatilise and separate the iron and titanium chlorides. The titanium chloride is re-distilled to separate traces of other chlorides, then treated with sulphuric acid to produce titanium sulphate and hydrochloric acid and the titanium sulphate treated to produce titanium oxide and sulphuric acid. The ferric chloride obtained is reduced to ferrous chloride and the latter electrolysed to produce metallic iron and free chlorine. The regenerated chlorine and that produced from the hydrochloric acid are used again in the first chlorination.—J. W. D.

Furnaces [*for melting metals*]. W. Oehm. E.P. 185,320, 27.8.21.

The combustion of gases from, *e.g.*, inferior fuel on a grate, is promoted by a small quantity of high-pressure air issuing through a small hole or jet at the back of one or more hollow burners of refractory material formed with flat converging slots or channels. The gases after complete combustion may be used for heating metal melting furnaces or, while still under pressure, for drying moulds. The high-pressure air may be preheated by being led in a serpentine course through passages adjacent to the burner device.—B. M. V.

Electric-furnace construction [*for reducing ores*]. W. E. F. Bradley. U.S.P. 1,427,436, 29.8.22. Appl., 22.7.18. Renewed 25.1.22.

The charge from a rotary furnace is fed through an inlet into an electric furnace of the tilting type provided with an outlet for removing the slag and reduced charge, the inlet also serving for conveying gases from the electric to the rotary furnace. A reducing gas is passed into the electric furnace through a carbon tuyère so situated that it is independent of the electrodes of the furnace and is covered by the molten charge while the furnace is in the receiving and reducing position, but is removed from the charge while the latter is being poured out of the furnace.—L. A. C.

Roasting furnace; Mechanical —— for pyrites etc. Erzröst Ges.m.b.H., and J. Walmrath. G.P. 351,351, 11.9.20.

The material slides on and under open oblique partitions in the centre of the oven without the use of poking or stirring devices. The partitions are so built that the gases evolved do not come in contact with the incoming ore, thus minimising production of flue dust.—A. C.

Tungsten metal; Process of reducing tungstic oxide to ——. W. F. Bleecker, Assr. to The Tungsten Products Co. U.S.P. 1,427,187, 29.8.22. Appl., 8.7.20.

Heat is applied to the interior of a charge composed of a mixture of tungstic oxides and a suitable reducing agent, the mass of material being provided with passages for the circulation of gases. —C. A. K.

Concentration of ores [*by flotation*]. G. E. Sheridan and G. G. Griswold, jun. U.S.P. 1,427,235, 29.8.22. Appl., 10.1.22.

An ore containing sulphides of iron and of one or more other metals is treated with a cyanide and an alkaline salt and then subjected to flotation under conditions unfavourable to floating the iron sulphide.—B. M. V.

Ores; Method of treating —— by volatilisation. H. R. Layng. U.S.P. 1,427,765, 29.8.22. Appl., 4.11.19.

The ore charge is heated so rapidly that the volatile elements in the ore are removed without any harmful reaction occurring.—A. R. P.

Zirconium ores; Treatment of ——. O. Hutchins, Assr. to The Carborundum Co. U.S.P. 1,427,816, 5.9.22. Appl., 22.9.20.

Pure zirconia is produced from zirconium ores by heating a mixture of ore and reducing agent so that part of the impurities in the ore is reduced to metal, and then separating the impurities from the zirconia.—J. S. G. T.

Beryllium; Process for electrolytically manufacturing compact metallic ——. A. Stock and H. Goldschmidt. U.S.P. 1,427,919, 5.9.22. Appl., 12.5.22.

Compact metallic beryllium is produced by electrolysing a fused bath of alkaline-earth fluoride containing a beryllium compound.—A. R. P.

Metals from metal alloys; Process for the separation and recovery of ——. G. J. Kroll. U.S.P. 1,428,041, 5.9.22. Appl., 21.9.20.

An alkaline-earth metal or magnesium is introduced into the metallic alloy or impure metal, so that the metallic constituent to be separated combines with the alkaline-earth metal to form a compound having a different melting point from and a specific gravity not more than that of the main metal. This compound is then separated from the remaining part of the alloy under treatment.—J. W. D.

Metals; Cleaner for and method of cleaning ——. J. H. Gravell. U.S.P. 1,428,084, 5.9.22. Appl., 4.6.21.

A mixture for cleaning metals consists of colloidal clay suspended in a suitable dilute acid together with a filler, acetone, and an alcohol of higher boiling point than ethyl alcohol.—A. R. P.

Metals; Composition for and method of preventing —— from rusting. Paint for and method of preventing heated [*metal*] *surfaces from rusting. Rust-resisting steel and method of producing same.* J. H. Gravell. U.S.P. 1,428,085–7, 5.9.22. Appl., (A) (B), 4.6.21, (C) 22.6.21.

(A) A rust-preventing coating for metals consists of castor oil, ethyl alcohol, and an alcohol having a higher boiling point than ethyl alcohol. (B) A paint for preventing heated metal surfaces from rusting contains at least 15% of a phosphate which on heating liberates enough phosphoric acid to form a substantial coating of the phosphate of the metal on its surface. (C) A rust-resisting steel consists of a body of metal into the surface of which a coating of phosphate has been pressed.—A. R. P.

Soldering solution. J. H. Gravell. U.S.P. 1,428,088, 5.9.22. Appl., 20.12.21.

A solution of zinc and ammonium chlorides containing fusel oil.—A. R. P.

Vanadium; Process of recovering ——. W. E. Stokes, Assr. to United States Processes, Inc. U.S.P. 1,428,616, 12.9.22. Appl., 19.1.21.

A vanadium ore is mixed with an alkali nitrate and heated.—B. M. V.

Condenser [*for zinc furnaces*]. C. A. Wettengel, Assr. to American Zinc, Lead, and Smelting Co. U.S.P. 1,429,214, 12.9.22. Appl., 4.3.18.

A tapering condenser has a fixed head with two openings at its larger end, one for introducing the zinc bars into the retort and the other for withdrawing the molten metal.—T. H. Bu.

Sulphide ores; Process for the treatment of slimy —— preparatory to roasting. Metallbank und Metallurgische Ges. A.-G. G.P. 355,885, 29.10.13.

The ore is subjected to a sulphatising roast, then moistened, and rendered granular before carrying out the roast proper. In this way the ore is not diluted with a binder which may cause trouble later.—A. R. P.

Iron and steel; Manufacture of ——. T. Rouse. U.S.P. 1,428,061, 5.9.22. Appl., 23.11.20.

See E.P. 152,073 of 1919; J., 1920, 787 A.

XI.—ELECTRO-CHEMISTRY.

[*Electric furnace and*] *apparatus for direct heating to high temperatures by resistance with simultaneous application of mechanical pressure.* F. Sauerwald. Z. Elektrochem., 1922, 28, 181—183.

An apparatus for heating rods of carbon, tungsten, or other material of high melting point to very high temperatures by the passage of an alternating current through the rod is described and illustrated in detail. It consists essentially of a horizontal fireclay tube with an outer sheet-iron casing, provided at each end with a water-cooled bronze electrode in which the rod is secured by two copper wedges. One electrode is fixed while the other is free to move on ball bearings inside a steel cylinder which prolongs the length of the furnace in this direction; in this way allowance is made for expansion and contraction of the rod during heating. Through the middle of the furnace, perpendicular to the axis, an arrangement, consisting of an upper and lower pestle which can be screwed tight against the bar or used for hammering it, is provided and a sight-hole closed with a mica window allows observation of the rod at this spot. The whole apparatus is made reasonably air-tight so that the heating operation may be carried out in a stream of suitable gas, such as hydrogen.—A. R. P.

Furnace for electric heating. A. H. Pehrson. E.P. 162,285, 25.4.21. Conv., 26.4.20.

Pairs of electrodes making contact at their inner ends, and covered with material protecting them from damage by gases or furnace charge, are introduced through the end walls, and at a suitable distance from the axis of a revolving or oscillating electric furnace.—J. S. G. T.

Electric furnaces. I. J. Moltke-Hansen. E.P. 171,096, 2.11.21. Conv., 3.11.20.

An electric furnace is heated by current applied to a resistance element consisting of granular material, e.g., granulated electrode carbon, contained in channels arranged about the furnace chamber and communicating in pairs at the top through a reservoir into which granular material is supplied to compensate for the consumption of this material during the operation of the furnace. Current is supplied only at the bottom of the respective channels.—J. S. G. T.

Electric furnace [*for production of calcium carbide*]. A. E. Reid. E.P. 185,136, 22.2.21.

An electric furnace for the production of calcium carbide comprises a hearth, a delivery outlet or outlets, electrodes projecting downwards and converging so that they may be adjusted towards and from the hearth and one another, and an additional electrode or electrodes, each located within a delivery outlet, for maintaining the carbide in a molten condition. Preferably, current is supplied to the additional electrodes at a lower voltage than to the downwardly projecting electrodes. The hearth of the furnace comprises a flat bottom portion and upwardly inclined sides in which the delivery outlets are placed.—J. S. G. T.

Electric furnace. E. H. Hurstkotte, Assr. to General Electric Co. U.S.P. 1,427,814, 5.9.22. Appl., 3.5.20.

A resistance heater composed of a number of dished discs in electrical contact at their peripheries but out of contact in their central regions, is arranged within a container, and a refractory shield is disposed between the heater and the charge in the furnace.—J. S. G. T.

(a, b) *Electric furnace.* (c) *Method of operating electric furnaces.* I. Rennerfelt. U.S.P. (a) 1,428,908, (b) 1,428,909, and (c) 1,428,910, 12.9.22. Appl., (a) 3.3.21, (b, c) 12.8.21.

(a) In an electric furnace, an elongated crucible is heated by current supplied to strings of carbonaceous resistance material disposed lengthwise along the crucible and separated from one another by electrically insulating material. (b) An electric furnace comprises an upper chamber separated by a conducting partition from a lower chamber, the walls of which are poor conductors of heat. At least two electrodes project into the lower chamber for generating an electric arc therein. (c) The charge in an electric furnace is heated first by free-burning arcs supplied with two-phase current, and then by means of arcs in contact with the surface of the charge and supplied with three-phase current, the relative distance between the arcs being changed.—J. S. G. T.

Electric batteries. Soc. Anon. "Le Carbone." E.P. 178,804, 10.2.22. Conv., 19.4.21.

The carbon or positive pole of a battery is immersed in an agglomerate of active material and depolariser, the former comprising a salt of cerium which acts as a catalyst during the discharge of the cell The agglomerate is contained in a calico or other bag, surrounded by a paste composed of gum tragacanth 40%, glucose 40%, sodium fluoride 2—3%, powdered pumice stone 17—18%. The agglomerate and paste are covered by anhydrous calcium chloride. The battery is put into operation by addition of water, and is characterised by the prevention of motion of the electrolyte and of the formation of local couples.—J. S. G. T.

Secondary cells or batteries for electricity storage [*; Means of preventing buckling of the plates of* ——]. C. G. Smith. E.P. 184,649, 30.6.21.

In storage cells employing lead plates, gypsum or plaster of Paris is employed to absorb the electrolyte and to separate and support the electrodes, which are inserted in a series of slots or pockets in the gypsum or plaster of Paris. The positive and negative plates are composed respectively of red lead and litharge, to which about 2% of powdered aluminium sulphate is preferably added.
—J. S. G. T.

Electric accumulators [; *Method of drying the negative plates of* ——]. A. Dinin. E.P. 184,658, 8.7.21. Addn. to 14,119 of 1914 (J., 1914, 928).

Lead electrodes used in accumulators are dried in a closed vessel in a heated stream of nitrogen, carbon monoxide, hydrogen, or other non-oxidising gas, the water vapour carried off by the stream being condensed and the gas kept in continuous circulation.—J. S. G. T.

Electrolytic apparatus [*for decomposition of water; Electrodes used in* ——]. A. W. Smith. U.S.P. 1,427,171, 29.8.22. Appl., 8.11.20.

Electrodes employed in the electrolysis of water consist of metals of the nickel group having their faces covered with spongy coatings of metals, such as nickel or platinum, which are unaffected by the electrolysis.—J. S. G. T.

Electrolytic method and apparatus. J. J. Sherwood, Assr. to Hooker Electrochemical Co. U.S.P. 1,427,236, 29.8.22. Appl., 20.3.20.

The gaseous product of an electrolysis (*e.g.*, electrolysis of common salt for production of hydrogen, chlorine, and caustic soda) is diverted from, and a supply of fresh electrolyte supplied to, the active electrode face at a point or points between the top and bottom of the electrode. The apparatus may consist of a cylindrical outer wall forming the cathode within which is a cylindrical diaphragm enclosing a hollow anode, provided with a number of annular projections, at different levels, which make a tight joint with the diaphragm without and project also into the hollow centre of the anode. Diagonal passages are formed in the annuli which serve to lead the evolved gases from the tops of the annular compartments to the central anode space and lead fresh electrolyte from the central space to the lower part of each annular outer space.—B. M. V.

Electrolytic apparatus and method of depolarising the same. W. D. Nickum. U.S.P. (a) 1,428,049 and (b) 1,428,050, 5.9.22. Appl., (a) 8.2.19, (b) 21.4.20. Renewed 5.11.21.

(a) The polarisation of an electrolytic circuit is reduced by the use of a transformer consisting of a low-tension primary coil energised by direct current, and a high-tension secondary coil connected with electrodes immersed in the electrolyte. (b) In an electrolytic apparatus as described under (a) the primary and secondary coils are inductively related so as to reduce the electrolytic polarisation when the current in the primary coil is varied owing to polarisation.—J. S. G. T.

Electrical etching; Apparatus for ——. *Process and apparatus for electrical etching.* R. M. Weeks, Assr. to Weeks Photo-Engraving Co. U.S.P. (a) 1,427,876, and (b) 1,427,877, 5.9.22. Appl., (a) 2.4.21, (b) 25.4.21.

(a) The plate to be etched is supported and employed as anode in an electrolytic bath and the cathode used is composed of material which is resistant to the action of the electrolyte and reduces the formation of hydrogen. (b) During the etching process the plate to be etched is moved in the plane of its face.—J. S. G. T.

XII.—FATS; OILS; WAXES.

Fatty acids and their glycerides; Action of the brush discharge on ——. E. Eichwald. Z. angew Chem., 1922, 35, 505—506.

If oleic acid is subjected to the action of the brush discharge the iodine value steadily falls, the mean molecular weight steadily rises, and stearic acid is produced. The increase in molecular weight per unit fall in iodine value increases from 6·3 at the beginning of the treatment to 43·5 after treatment for 22 hrs. About 11% of the oleic acid is converted into stearic acid, and this conversion occurs in an atmosphere of air or nitrogen as well as in an atmosphere of hydrogen, though working under the latter conditions gives the slightly higher maximum yield of 15% of stearic acid. It is considered that the bombardment of the molecules causes hydrogen atoms to become detached in a highly active state, and that they immediately saturate the double bonds of other molecules of oleic acid, leaving some highly unsaturated molecules which polymerise and cause the increase in molecular weight. Glycerides show similar effects under the brush discharge, the glyceryl part of the molecule being unaffected. The resulting polymerised oils have high viscosities and flat viscosity-temperature curves and are of value as lubricants. Owing to the possibility of intra-molecular saturation of double bonds in the case of glycerides, the increase of molecular weight in this case becomes even more marked in the later stages of treatment than in the case of the free fatty acids.—H. C. R.

Coconut oil; Oleic acid content of the free fatty acids from the soap stock obtained on refining ——. F. Wittka. Z. Deuts. Oel- u. Fettind., 1922, 42, 377—378. Chem. Zentr., 1922, 93, IV., 598—599.

A comparison of the iodine values of crude and neutralised coconut oils obtained from the rind and from the kernel showed that the hydrolysis of the glycerides begins in the rind of the copra and proceeds faster there than in the inner layers. The oil from the rind has acid value 7·5 and iodine value 38·7, but bears only a small proportion to the total oil content. The further the hydrolysis proceeds, the more free fatty acids will be formed in the white inner layers of the copra and the smaller proportion will the free fatty acids formed in the rind bear to the whole. The characters of the acid oils obtained from such copra will therefore approach those of normal coconut oil. Strongly acid coconut oil will therefore give an acid oil with normal (low) iodine values. Good quality coconut oil, however, will give an acid oil with a high iodine value, and this will be the higher, the better the refining process has been, *i.e.*, the smaller the quantity of neutral fat hydrolysed during the process. Commercial acid coconut oils showing high iodine values cannot on this account alone be safely condemned as adulterated.—H. C. R.

Hydrogenation of oils; Promoters of the ——. I. S. Ueno. Kôgyô-Kwagaku Zasshi (J. Chem. Ind., Japan), 1922, 25, 777—783. (*Cf.* J., 1919, 20 a.)

Experiments with herring and cottonseed oils showed that the hydrogenation of oils is accelerated by the presence of small quantities of fatty or aromatic acids. The results obtained with 2—3% of palmitic, oleic, butyric, stearic, and benzoic acids, using nickel or nickel sulphate (0·3—0·5% as Ni) as catalyst are given in tables.—K. K.

Brassidic anhydride, and preparation of anhydrides by means of phosgene. D. Holde and K. Schmidt. Z. angew. Chem., 1922, 35, 502—503.

Brassidic anhydride, brassidic acid, and ethyl brassidate were prepared from erucic acid and its corresponding derivatives by isomerisation by means of nitrous acid. Brassidic anhydride crystallised from alcohol in small needles, m.p. 64° C., had the theoretical iodine value, and sp. gr. 0·835 at 70°/4° C. Ethyl brassidate formed leaflets, m.p. 30°—30·5° C., $n^{35}=1·4587$. The anhydrides of the fatty acids of cod liver oil were obtained in an impure condition, containing chlorine, by the action of carbonyl chloride on their alkali salts. They formed pasty products of higher melting point than the corresponding glycerides and acids. The difference frequently observed between the acid and saponification values of the acids of fatty oils may possibly be due to the presence in the acids of a proportion of anhydrides, which do not react normally with cold alcoholic hydroxide solutions. —G. F. M.

Saponification of oils and fats; Studies in the ——. H. M. Langton. J. Oil and Colour Chem. Assoc., 1922, 5, 41—75.

The theory of the hydrolysis of oils and fats is reviewed and the technical methods of hydrolysis are enumerated and described. A summary is given of previous work on the rate and extent of the hydrolysis of different oils and fats and an account is given of the author's large-scale experiments on the rate and extent of the hydrolysis of tallow, palm oil, linseed oil, palm kernel acid oil, No. 1., No. 2 and No. 3 whale oils, using lime and magnesia as catalysts in the autoclave process. In all cases a constant steam pressure of 8 atm., a charge of 3 tons of oil or fat, an amount of catalyst equal to 2½% of the weight of oil, and a period of treatment of 10 hrs. were employed. The results obtained are shown in a series of curves which are of the exponential type, the greater part of the fat being hydrolysed after about 4 hrs. and the rate of hydrolysis after that period being exceedingly slow. Magnesia was the more effective catalyst in the case of tallows, palm kernel acid oil, and the whale oils, whereas lime was superior in the case of palm oil. In the case of linseed oil the rate and extent of hydrolysis were the same with each catalyst. Using magnesia as catalyst, the tallows were hydrolysed most quickly in the first few hours and in decreasing order of speed whale oils, linseed oil, palm oil and palm kernel oil. Beef tallow hydrolyses much more quickly with lime than does mutton tallow under the same conditions. In the case of whale oils the rate of hydrolysis is in the order No. 1, No. 2, No. 3, No. 1 giving the highest value. The practice of blowing the glycerin solution from the autoclave after about 4—5 hrs. and re-starting the hydrolysis was found to offer no practical advantage. A table of average extents of hydrolysis after treatment of various fats with lime and magnesia for 8 hrs. under the conditions outlined above is given. These are the averages of 625 3-ton charges. In general magnesia was found to be more effective than lime.—H. C. R.

Total fat in soaps; Simplification of Goldschmidt's titration method for determining the ——. M. Jakes. Seifensieder Zeit., 1922, 49, 431—432. Chem. Zentr., 1922, 93, IV., 449.

The determination of total fat in curd soaps from coconut or palm-kernel oils and resins according to the standard methods often offers difficulties. The petroleum spirit does not completely dissolve the resin and in drying the fatty acids a temperature of 50°—55° C. is not high enough to remove the petroleum spirit. The following methods are suggested: (a) 7—10 g. of soap is dissolved in water, decomposed with excess of acid, and extracted with ether, washed with water or salt solution, the ethereal solution poured off, the separating funnel washed out with alcohol, and the solution titrated. (b) 50 g. of soap is dissolved in water, decomposed with excess of acid and allowed to settle. The fatty acid layer is poured into hot water two or three times, and 5 c.c. of the clear washed acids is filtered, dissolved in alcohol and titrated. The errors introduced by the solubility of the fatty acids in water and of water in the fatty acids are very small.—H. C. R.

Oil emulsions; Preparation of —— by means of colloidal silicic acid and the relationship to the processes of tuberculosis. S. P. Kramer. Kolloid-Zeits., 1922, 31, 149—150.

When animal or vegetable oils are added to a solution of sodium silicate (2 per 1000) a fine and very stable emulsion is formed at once. The oil drops are so small that many of them exhibit the Brownian movement. The formation of the emulsion takes place as follows: the fatty acid of the oil combines with the sodium to form a soap and liberates colloidal silicic acid which then acts as a protecting colloid. The addition of acid produces a silicic acid gel emulsion and the addition of lime water causes coagulation, forming a cheese-like coagulum and a thin liquid. The above changes are shown to be similar to the processes occurring in the development of tuberculosis. —J. F. S.

Boring and cooling oils. Kaleta. *See* IIa.

Patents.

Regenerating fuller's earth, charcoal and the like purifiers of fats and fatty oils and of catalysts used in hydrogenating fats and fatty oils; Method for ——. E. R. Bolton and E. J. Lush. E.P. 185,174, 24.5.21.

The material to be regenerated is subjected to the action of superheated steam until the mass is raised to a temperature of 230°—300° C., whereby the oil content is hydrolysed and recovered as distilled fatty acids and glycerol. A vacuum may be employed to expedite the distillation of the hydrolysed oil.—H. C. R.

Fish and other oils; Method and apparatus for treating ——. V. F. Feeny. From Title Guarantee and Trust Co. E.P. 185,247, 13.6.21.

The oil is deodorised and sterilised by circulating it through a chamber in which it is exposed to the action of ozonised air and preferably to the action of sunlight. It is delivered at the top of the chamber so as to fall in the form of rain through the upward air current, is continuously withdrawn from the base of the chamber for agitation and heating, and is thereafter returned to the top of the chamber or passed on for subsequent treatment. The oil may also pass in a thin film over the walls of the chamber, and be subsequently treated with pulverulent material and filtered. Heated air may be passed through the chamber, which may also be provided with means for raising the pressure inside it.—H. C. R.

Fatty matter; Recovery of —— from raw materials of organic origin. F. Bergius. G.P. 350,634, 4.8.17.

The raw material, *e.g.*, peat, lignite, etc., is mixed with water, to which may be added a basic material, *e.g.*, soda, and is heated to a temperature not exceeding 300° C. under high pressure. The liquid containing fatty matter is separated from the residue. Raw lignite, for example, containing 50% of water, may be heated with about double the quantity of a 10% soda solution to 275° C. at

90 atm. pressure for 6 hours. After cooling, the mass is filtered and the filtrate is acidified with sulphuric acid, causing separation of fatty acids. —A. G.

Lubricating oils, leather grease, artificial vaseline, lanolin-like materials and the like; Production of highly viscous —— from mineral, vegetable and animal oils. Plauson's Forschungsinstitut G.m.b.H. G.P. 353,222, 20.4.21. Addn. to 347,084 (J., 1922, 300 A).

Vegetable waxes are used in place of bitumen or crude or bleached montan wax. The products obtained from Japan wax, carnauba wax, or beeswax, by treatment with aldehydes in the presence of alkalis, if necessary with the addition of polyhydric alcohols, give, on melting with oils, highly viscous, vaseline-like products, which can be incorporated with water by intimate trituration. —A. G.

Fatty acids with several double linkages or of their glycerides; Conversion of —— into oleic acid-like fatty acids or their soaps. C. Stiepel, Assr. to Persapol Ges. U.S.P. 1,429,114, 12.9.22. Appl., 14.9.20.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Graphites and other pencil pigments. C. A. Mitchell. Analyst, 1922, 47, 379—387.

The author gives a further account, illustrated by photomicrographs, of the differences in the markings made by various graphites (*cf.* J., 1919, 381 T), lead-antimony alloys, etc., and a correlation of the microscopic appearances of these markings with the chemical composition of the pencil pigment. The materials used included a number of old graphite or compressed graphite pencils, samples of old Borrowdale graphite, and modern graphites and graphite pencils, and the conclusions previously drawn were confirmed. The pigments in a number of coloured pencils were examined both chemically, and by microscopical observation of their markings on paper. The pigment in blue pencils is either an aniline dye, Prussian blue or other mineral pigment, or a mixture of both. In red pencils the pigment is mostly red lead. Chemically the markings may often be differentiated by their behaviour with $N/1$ potassium hydroxide, or with hydrochloric acid, and differences may also be noted in the reactions given by them for iron. Microscopically differences may be noted in the colour, and the disposal of the pigment on the paper. —G. F. M.

Coumarone-resin; Preparation of ——. S. Hirano. Kôgyô-Kwagaku Zasshi (J. Chem. Ind., Japan), 1922, 25, 827—833.

On slowly adding 5 c.c. of concentrated sulphuric acid to 100 c.c. of purified coal tar naphtha, b.p. 155°—185° C., with constant stirring, coumarone-resin is produced, with a yield of 9·53% of the naphtha. The naphtha should be previously washed with soda lye (sp. gr. 1·22) and dilute sulphuric acid (sp. gr. 1·20) to remove tar acids and bases, and freed from water. If the alkali washing be omitted, the same yield is obtained, but the product is darker in colour. The initial temperature of the oil should be as low as possible and rise of temperature during the reaction avoided. When more oil is used at a time, the quantity of the acid should be decreased to avoid oxidation. A paler resin is obtained by washing the reaction product with alkali. As polymerisation reagents, stannic chloride (5 c.c.) gives a hard and pale resin (m.p. 85° C.), the yield being 6·06 g. from 100 c.c. of oil, while aluminium chloride (10 g.) gives a soft and dark resin (m.p. 38° C.) with a yield of 32·5 g.—K. K.

Sedimentation analysis. Von Hahn. *See* XXIII.

Patents.

Condensation products of phenolic bodies with aldehydic compounds; Manufacture of ——. Lorival Mfg. Co., Ltd., and A. A. Drummond. E.P. 184,961, 7.7.21.

To the initial condensation product obtained by the interaction of phenols with formaldehyde is added a proportion of glycerin (*e.g.*, 70% aqueous glycerin) such that the proportion of mineral acid used as accelerator is 1 g.-equiv. to at least 900 g. of glycerin.—A. de W.

Artificial [phenol-formaldehyde] resins; Production of ——. A. Heinemann. E.P. 184,984, 27.7.21.

An alkali glycerate is added to artificial resins obtained from phenols and formaldehyde after the elimination of water therefrom, for the purposes of minimising brittleness and increasing toughness, or if desired, raising the melting-point and reducing solubility.—A. de W.

Rosin; Compound for hardening —— and method of using same. W. H. Scheel. U.S.P. 1,428,120, 5.9.22. Appl., 25.3.22.

Coral lime (about 1%) is compounded with rosin whilst in the state of fusion, and the fused mass diluted with a liquid solvent to the proper consistency of a rosin varnish.—A. de W.

Coating composition and process of producing the same. Paint vehicle. W. A. Collings. U.S.P. (A) 1,428,272 and (B) 1,428,273, 5.9.22. Appl., 5.11.21 and 28.2.22.

(A) Hot raw linseed oil is gelatinised by the incorporation of a water-insoluble soap, *e.g.*, aluminium stearate, the jelly allowed to age, and Portland cement added thereto in sufficient proportion to form a stiff paste. (B) A petroleum distillate of high iodine value is subjected to distillation or blown with air to free it from its contained pitchy or waxy matter and a water-insoluble metal soap incorporated therein.—A. de W.

Inks and water-colours; Manufacture of ——. Plauson's Forschungsinstitut G.m.b.H. G.P. 355,117, 22.6.21.

Aqueous colloidal dispersions of substances such as clay, kaolin, phosphates, zirconium earths, metallic oxides, lime and iron compounds, or of other insoluble coloured mineral substances are ground with soluble organic dyestuffs and a protective colloid in a Plauson colloid mill. By this method, only about one-tenth of the usual amount of organic dyestuff is required.—A. J. H.

Rust-preventing coatings. U.S.P. 1,428,085-6. *See* X.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Latex and rubber from individual trees. III. Difference in properties of rubber from different trees. Are the properties of rubber from one tree constant? O. de Vries. Comm. Central Rubber Stat. Buitenzorg, 1922, No. 29, 146—162.

Twelve good-yielding trees, on one estate, gave from 9·6 to 68·4 g. of rubber per day. The rubber content of the latex varied from 25 to 46%, and although often very constant over long periods for one tree, sometimes underwent change from alteration in tapping system and other causes. For some trees the tensile strength of the rubber was consistently low. The rate of vulcanisation was fairly constant for each tree and the "slope" in almost all cases fell between 35 and 38. Wide variations, however, were found in the viscosity, which was not always constant for the same tree. (*Cf.* J., 1920, 665 A.)—D. F. T.

Latex and rubber from young trees. O. de Vries. Comm. Central Rubber Stat. Buitenzorg, 1922, No. 31, 296—309.

In the rubber from trees between 6 and 15 years old the differences in properties are small. With trees 3 to 4½ years old, however, the rubber content of the latex was low and the specific gravity tended to be high. The rubber, especially in the form of sheet, showed marked "shortness," and the viscosity was very low, particularly for crêpe. The rate of vulcanisation proved exceptionally high, whilst in "slope" and tensile strength the vulcanised rubber was inferior to the product from older trees.—D. F. T.

Latex and rubber; Influence of soil upkeep on ——. O. de Vries. Comm. Central Rubber Stat. Buitenzorg, 1922, No. 31, 289—295.

No improvement was observable in the rubber from trees over a period of three months during which the ground was kept in good condition and free from weeds, after having been neglected for twelve months.—D. F. T.

Hevea latex; Presence of quebrachitol and sugar in —— under different circumstances. W. Spoon. Comm. Central Rubber Stat. Buitenzorg, 1922, No. 30, 269—287.

Making the assumption that the sugar present in latex is sucrose, comparative estimation of the proportion of quebrachitol is possible by measurement of the optical rotation of the protein-free serum before and after inversion of the sucrose. The removal of protein from the serum can be effected by precipitation with alcohol. Tapping the trees on alternate days instead of daily causes an increase in the proportion of rubber and sugar in the latex and a decrease in the mineral substances and in the quebrachitol. During the first few months after the change the yield of latex per tree decreases by about 40%, but subsequently rises gradually.—D. F. T.

[*Rubber latex;*] *Experiments* [*on* ——] *with Boehringer's coagulating powder* [*aluminium lactate*]. W. Spoon. Comm. Central Rubber Stat. Buitenzorg, 1922, No. 29, 140—145.

The coagulant, which consists chiefly of aluminium lactate, gives a rubber inferior to that obtained with acetic acid in tensile strength, rate of vulcanisation, and viscosity. The use of lactic acid as a coagulant does not harm the rubber, but alum yields a poor grade of rubber, similar to that obtained with the aluminium lactate.—D. F. T.

Rubber latex in paper making. Kaye. *See* V.

XV.—LEATHER; BONE; HORN; GLUE.

Hide soaking experiments. B. S. Levine. J. Amer. Leather Chem. Assoc., 1922, 17, 417—430.

Pieces of hide were soaked in tap water under normal, aerobic, and anaerobic conditions. The hair became loose in the shortest time, viz., 10 days, by the action of anaerobic bacteria. The quantity of water compared to hide should not be greater than 10:4, preferably less. The soak liquor from experiments under aerobic conditions (with a current of air passing during the experiment) were thick and difficult to filter, whilst that from experiments under anaerobic conditions (atmosphere of carbon dioxide) was clear and easily filtered. The number of bacteria per c.c. was less in the anaerobic method than in any of the others. Soaking and hair loosening can be effected in one operation.
—D. W.

[*Hides;*] *Versatility of a plumping method* [*for* ——]. H. C. Reed. J. Amer. Leather Chem. Assoc., 1922, 17, 460—482.

Two grms. of dry hide powder was weighed into a wide-mouthed 6-oz. bottle fitted with a rubber stopper. 100 c.c. of the solution to be tested was added, the contents shaken and allowed to stand for 20 hrs. The solution not retained by the hide powder was filtered off through a cotton plug into a measuring cylinder. The plumping action was expressed in ratio to the plumping action of distilled water as unity. Curves are given showing the plumping action of different acids at different concentrations. Sulphuric acid is differentiated from hydrochloric acid and both from organic acids. The plumping ratio of caustic soda, the repressive action of salts on plumping by lactic acid, sulphuric acid, and caustic soda, and on hide powder swollen by water, are shown graphically. Experiments have been carried out on the plumping ratios of tanning materials, the effect of tannin on hide powder plumped with acid, and the effect of mixtures of tannin and acid on hide powder swollen by water.—D. W.

Goran (Ceriops Roxburghiana) bark: optimum temperature and state of sub-division for maximum extraction. J. A. Pilgrim. J. Soc. Leather Trades' Chem., 1922, 6, 255—260.

In Dhavale and Das's work (J., 1921, 709 A) the ground bark was sifted whereas in practice the coarsely ground material contains some fine powder which is very rich in tannin. The solutions analysed by Dhavale and Das were not of analytical strength. The author has made certain corrections which indicate that the 60-mesh material yields most tannin.—D. W.

Tannin analysis. III. V. Kubelka and B. Köhler. Collegium, 1922, 167—176. (*Cf.* J., 1921, 312 A; 1922, 773 A.)

Experiments show that the results given by the official method of tannin analysis vary considerably according to the concentration of tannin in solution, whereas those obtained by the filter bell method are almost independent of that factor. The differences between the results of the two methods are not caused by the stronger chroming of the hide powder. The official shake method depends on an equilibrium condition which cannot give the best results. The authors favour the filter bell method. —D. W.

Synthetic tans; Comparative observations of the tanning properties of vegetable tanning materials, synthetic tans, and mixtures of vegetable tanning materials with ——. S. Kohn, J. Breedis, and E. Crede. J. Amer. Leather Chem. Assoc., 1922, 17, 450—460.

Hide substance will absorb much smaller quantities of "syntans" than of vegetable tanning materials, but if mixed in certain proportions both act cumulatively. The active principles of syntans are acids having a higher degree of ionisation than the acids in vegetable tannins and approaching that of sulphuric acid. Syntans can be produced which do not manifest the disadvantages of sulphuric acid. The different syntans can be distinguished by evaporating a sample to dryness in a drying oven at 80° C. Unstable syntans decompose under such conditions and the residue will contain some organic base insoluble in water. The acidity will also have increased. Leathers tanned with syntans show free mineral acid by the Procter-Searle method of determination. To determine free mineral acid the leather should be extracted with water to leach out the acids and Immerheiser's ether method applied to distinguish between sulphonic and sulphuric acids. Another useful test is to soak a piece of muslin in a solution of the syntan and dry it out. Free sulphuric acid will rot the muslin, whilst a stable syntan will not affect its strength.—D. W.

Chrome tannage; One-bath —— with chrome alum. P. Chambard and L. Meunier. Chim. et Ind., 1922, 8, 325—329.

Experiments with basic chrome alum liquors show that for a given basicity the amount of chromic oxide fixed in the skin when it is saturated is independent of the concentration provided that the liquor is renewed several times and sufficient time is allowed. With normal chromium compounds the amount of chromic oxide fixed by the skin when it is saturated diminishes with the concentration. —D. W.

Vegetable-tanned leathers; Determination of water-soluble matter in ——. W. J. Chater and D. Woodroffe. J. Soc. Leather Trades' Chem., 1922, 6, 247—255.

Experiments with the official method of determining water-soluble matter in vegetable-tanned leathers show that it is in error to the extent of 10—30%. An additional litre of percolate should be collected, the water-soluble matter determined in an aliquot portion thereof and added to that determined in the official method. The yield of soluble matter from leathers plotted against time of extraction gives curves of the same type for different leathers, all of which appear to follow closely laws of an exponential type.—D. W.

Gelatin and glue; Evaluation of ——. R. H. Bogue. J. Ind. Eng. Chem., 1922, 14, 435—441.

Commercial gelatin and glue should be evaluated in terms of proportion of pure and unhydrolysed gelatin which is contained in the material. Glue as an adhesive should be evaluated in terms of the strength of the joint made with the material. The glue with the largest amount of unhydrolysed gelatin produces the strongest joint. If the viscosity is kept constant the jelly content and joint strength vary as the jelly consistency, whilst if the latter is constant these properties vary as the viscosity. The jelly consistency and the viscosity bear the same relation to the melting point, and the latter appears to indicate the gelatin content and the joint strength. Most melting point determinations are inexact, but a value for the melting point may be obtained by plotting the curve of viscosity at decreasing temperatures and extrapolating to the temperature where the viscous flow would be zero. The same order of differentiation may, however, be obtained by a single determination of the viscosity at 35° C., using the equivalent of 18 g. of dry glue made up to 100 g. with water. The hydrogen ion concentration of a 1% solution should be measured. The viscosity at 60° C., the jelly consistency, the foam test, the grease test, appearance, and odour should also be determined. The grade designation of the product may be expressed by consecutive numbers, 1 being the lowest, and corresponding to a viscosity of the 18% solution (dry basis) at 35° C. of less than 20 centipoises and each succeeding numerical increase in the designation corresponding to an increase of 10 centipoises.—D. W.

Patents.

Tanning of hides and skins. P. J. C. Margotton. E.P. 184,955, 30.6.21.

Hides and skins which have been worked in a stream and tawed and have been fleshed and pressed, especially hides intended for use in the manufacture of gloves, are worked in a solution containing, *e.g.*, 2 g. of chromic acid and 2 c.c. of sulphuric acid per 50 g. of hides, in 3 l. of water. The solution is contained in a "fulling prism" consisting of a prismatic box of polygonal section rotating about a vertical shaft parallel to its axis. The box is separated into two compartments by a grating inclined to the axis of the prism at an angle of about 60°. Another grating parallel to and near the base of the prism prevents the hides from blocking the end of an aerating pipe leading into the space between the base and the grating. When the hides are completely impregnated with the solution, they are allowed to drain, treated successively with sulphur dioxide and ammonia, washed to remove ammonia and ammonium salts, treated with hot air charged with alcohol vapour, impregnated with oil, heated to 45°—50° C., degreased and dried. Means are provided for recovering sulphur dioxide, ammonia, and alcohol vapour.—L. A. C.

Tanning hides and skins. E. W. Merry, Assr. to Pyrotan Leather Corp. U.S.P. 1,427,221, 29.8.22. Appl., 11.2.19. Renewed 16.5.22.

Hides are agitated in contact with a solution containing a soluble aluminium salt and a soluble pyrophosphate. The temperature is not allowed to exceed 107° F. (42° C.).—D. W.

Leather grease. G.P. 353,222. *See* XII.

XVI.—SOILS; FERTILISERS.

Soil-reaction; Change of —— by manuring. I. S. Osugi and N. Soyama. Ber. Ohara Inst. Landw. Forsch., 1921, **2**, 79—93.

A number of plots were treated with different fertiliser mixtures, and periodic observations of the H-ion concentration of the soil were made by means of 1:10 water-extracts. No regularity was observed in the changes of p_H values due to the fertilisers used, nor was there any correlation between p_H values and crop yields. The only distinct effects were those due to the alkalinity of lime, lime-nitrogen (crude calcium cyanamide), and potassium carbonate. Continuous application of the same fertiliser mixture to the same soil does not cause an accumulation of reaction changes due to the fertiliser. The reaction of irrigation water may modify or obliterate that produced by added fertilisers.—A. G. P.

Colloidal clay [in soils]; Quantitative determination of ——. R. Sokol. Internat. Mitt. Bodenkunde, 1921, **11**, 184—211. Chem. Zentr., 1922, **93**, IV., 704.

The clay, suspended in water, is flocculated with *M*/10 sodium chloride, and the volume of the sediment is measured, immediately, and also after 24 hrs. The ratio of the two values gives the "colloid number." The addition of the salt produces a flocculent precipitate, which contains in addition to colloidal matter all the dust and other coarse suspended matter; the volume of the latter may be determined in a similar manner without the use of salt. Clays were graded by Atterberg's method, and the proportions of coarse and fine particles in grade A (less than 0·002 mm. diam.) estimated from the amount of deposit after 3 and 17 days respectively. Microscopical examination showed that the former had an average diameter of 0·0007 mm., and the latter 0·0003 mm., which values agree well with Stokes' formula. The flocculation method enables the diameters of the various particles to be estimated, whilst the determination of the hygroscopicity, as recommended by Mitscherlich, only gives a rough idea as to whether few or many small particles are present, and gives no evidence as to their dimensions.—A. B. S.

Lime-sulphur mixture. Harukawa. *See* XIXb.

Patents.

Acid phosphate or superphosphate; Apparatus for manufacturing ——. T. J. Sturtevant, Assr. to Sturtevant Mill Co. U.S.P. (a) 1,428,920, (b) 1,428,921, and (c) 1,428,922, 12.9.22. Appl., (a) 19.4.21, (b) 26.4.21, (c) 24.5.21.

(a) A semi-liquid mixture of ground phosphate rock and acid is delivered to a series of containers which are advanced continuously for a sufficient distance to allow the mixture to solidify, the solidified mixture being discharged from the container during transit. (b) A mixture of ground phosphate rock and acid is delivered into the upper end of a den, and passes, on becoming spongy, into a disintegrator disposed below. Means are provided for supporting the materials above the disintegrator. (c) An apparatus for manufacturing superphosphate comprises a den having a fixed floor and rear walls, and roof and side walls which may be moved so as to expose the block of superphosphate formed in the den. The phosphate is fed toward the rear wall of the den to a disintegrator.—J. S. G. T.

Nitrogenous manures; Manufacture of ——. D. Lo Monaco. E.P. 184,833, 7.4.21.

See U.S.P. 1,402,638 of 1922; J., 1922, 151 a. In addition to humus, organic refuse of all kinds (manure, oil-seed cakes, lemon refuse, ground horns and nails, dried blood, chrysalides, bones, leather scrap, cloth refuse) may be treated by the process described. [Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 2662 of 1873 and 4103 of 1875.]

Nitrolim; Process for making granular —— from nitrolim and sulphite-cellulose pitch. A. Mann. G.P. 313,129, 24.1.18.

Pulverised nitrolim and pulverised sulphite-cellulose pitch are mixed and cellulose waste lye is added, in one or more operations, until a plastic mass is obtained, which is then heated on rippling rolls or plates until dry. The product is free from dust. Short-fibred refuse from cellulose and paper manufacture may be added and increase the fertilising value of the mass.—H. C. R.

Liquid manure; Process for making an artificial ——. G. Cyliax. G.P. 355,038, 25.7.19.

Natural liquid manure or a pure culture of the bacteria contained in it is mixed with water, meal from leguminous plants, especially lupins, straw-meal, earth and sodium bicarbonate, and kept for about 48 hrs. at 44°—48° C. This manure encourages the development of useful soil-bacteria. An application of 3 cubic metres per quarter hectare every four or five years is specified.—H. C. R.

Artificial liquid manure; Production of an ——. G. Cyliax. G.P. 355,991, 3.7.21. Addn. to 355,038 (*cf. supra*).

Instead of using natural liquid manure, the product obtained as described in the chief patent is employed to inoculate fresh material.—A. B. S.

Phosphatic fertiliser; Process for making a ——. A.-G. für Anilin-Fabrikation. G.P. 355,180, 12.10.20.

Low-grade phosphate rock is decomposed with nitric acid, and the solution and residue are worked up separately and afterwards united. Whereas phosphate rocks rich in iron and aluminium when decomposed with nitric acid in the usual manner and neutralised, only contain 30—40% of the total phosphate soluble in citric acid, a product is obtained by this process containing 85—90% of its phosphate soluble in citric acid.—H. C. R.

Seeds; Treatment of ——. A. W. Beer. G.P. 354,658, 18.4.20.

A solution of the complex salt, acetamide-mercury chloride, containing 0·05% Hg, renders spores of mildew etc. inactive. The solution is less harmful to the germ centre of the seed than mercury chloride itself and can be applied to oil-seeds not easily treated by other means.—A. C.

Fungicide and insecticide. G.P. 355,829. *See* XIXb.

XVII.—SUGARS; STARCHES; GUMS.

Extraction of sugar from beet molasses by a modification of the baryta process. H. Manoury. Bull. Assoc. Chim. Sucr., 1922, **39**, 413—421.

Barium sulphide (obtained by the reduction of the sulphate by heating with charcoal to 1000°—1200°

C.) is treated with hot water, and the resulting liquor, after filtration, mixed with zinc oxide and heated, the solution of barium hydroxide thus obtained being used for the preparation of barium monosaccharate, which is filtered off in presses. In order to decompose this saccharate cake, it is heated with a solution of zinc sulphate, the solution of pure sugar obtained being worked up as "refined." Regarding the by-products resulting from this method of operating, the zinc sulphide is treated with sulphuric acid to produce the zinc sulphate used for the decomposition of the saccharate cake; while the mixture of barium sulphate and zinc hydroxide resulting from the decomposition of the saccharate cake is mixed with the wash-waters from the process of leaching out the barium sulphide, the barium hydroxide filtered off, and the residue (consisting of zinc sulphide and barium sulphate) treated with sulphuric acid for the recovery of more zinc sulphate. It is stated that this process is in routine operation in a sugar factory in Spain.
—J. P. O.

Explosion of sugar dust, its causes, and prevention. P. Beyersdorfer. Z. Ver. deuts. Zuckerind., 1922, 475—533.

Experiments are described showing that the temperature necessary for the ignition of sugar dust is 410° C. in air, and 371° C. in oxygen, and that these results are influenced considerably by the presence of relatively inert gases, carbon dioxide having a considerably stronger depressing effect than nitrogen. Dust clouds having a concentration less than 17·5 g. or more than 13·5 kg. of sugar per cub. m. of air will not explode. The ignition of sugar dust in air may also be due to an electrical cause, experiments being described demonstrating that when sugar dust is whirled with rapidity through air it gives rise to electrical charges upon both dust and air to the extent of several thousand volts. An "aerosol" is then formed, and when the maximum capacity is reached a discharge with flashing occurs, the stages concerned being the formation of ozone and nitrogen pentoxide, reaction of these gases with the extremely fine dust, and lastly the explosion. Triboluminescence may arise during the disintegration of the sugar in the crushing machines, but the occurrence of this phenomenon cannot give rise to dust explosions. As precautionary measures to be observed in practice, it is advised that dust formation should be reduced to the minimum by effecting disintegration in three stages, the machines recommended being jaw crushers for the preliminary reduction, roller mills for the coarse grinding, and stamping mills for the finest comminution. Bucket elevators, steel (not balata) belts, and dust-tight screw elevators are the most suitable means for the removal of the ground material from the disintegrating machines; while for the withdrawal of the dust a system of wet separation combined with a "cyclone" is the only permissible one, this portion of the plant being decentralised. Wires should be run to earth from all parts of the machines where static electricity is likely to be generated. A certain means of protection against any danger of explosion, whether from thermal or electrical causes, is the gas-tight enclosure of the disintegrating and conveying machines and the displacement of the air within by a relatively inert gas, preferably carbon dioxide, or possibly washed and filtered flue gases.—J. P. O.

Sucrose; Inversion of —— by alkaline copper solution. L. Maquenne. Bull. Soc. Chim., 1922, 31, 799—806.

The author has previously pointed out that the reducing power of sucrose towards alkaline copper solution is not constant but is dependent on the quantity of invert sugar present and on the concentration of the solution (*cf.* J., 1915, 1263; 1916, 268). Canals' results (J., 1922, 608 A) are criticised on the ground that necessary precautions were omitted. Details of the author's method for the determination of reducing sugars in presence of sucrose (J., 1916, 320, 373) are repeated with examples, and tables for calculating the results are given.—H. J. E.

Patent.

Dextrin; Method and apparatus for manufacturing ——. J. J. Merrill, Assr. to Corn Products Refining Co. U.S.P. 1,428,604, 12.9.22. Appl., 23.4.17.

In the preparation of dextrin, heating is carried out in a cylindrical vessel having a door in its side wall and heated by steam pipes arranged adjacent to the side wall, surrounding the major part of the vessel and connected to the source of heat supply by means of headers arranged on opposite sides of the door.—W. H. G.

XVIII.—FERMENTATION INDUSTRIES.

Malt; Speckled ——. F. A. Mason and F. Brown. Bull. Bur. Bio-Tech., 1922, No. 6, 188—191.

A sample of high-dried malt containing 10% of speckled grains or "magpies" has been examined. Contrary to the view expressed by Frew (J., 1898, 330), the speckling of the corns appears to be due to the production of one or more melanoidins in the outer cells of the husks, owing to certain conditions of moisture content and to the nature of the kiln gases, these being determined by the ventilation and temperature. The yields of extract and the specific rotations of the wort obtained from the speckled and from normal grains agree so closely that differences between the endosperm contents in the two cases seem unlikely; the only variable feature is the deeper colour of the wort given by the speckled malt. Except for this increase in tint, the brewing value of a malt is not impaired by the presence of speckled corns.—T. H. P.

Malt; Proteolytic enzymes of ——. H. Lundin. Biochem. Zeits., 1922, 131, 193—218.

The optimum p_H for malt peptase in malt is 3·7—4·3 and in green malt 3·2. There is no malt peptase in malt germ. The malt tryptase of green malt and of malt germ acts best at p_H 6·3. At the optimum p_H neutral salts have little action. The autolytic process in malt is conditioned by the various enzymes present, each having an optimum p_H; the optimum value however for autolysis is 4·3—5·0 in malt, 4·4 in green malt, and 6·3 in malt germ.
—H. K.

Yeast; Influence of mineral spring water on the carbohydrate interchange in ——. P. Mayer. Biochem. Zeits, 1922, 131, 1—5.

The use of Karlsbad water as a solvent for the sucrose in yeast fermentation leads to an increased production of glycerol and a diminished production of alcohol. Solutions made up from Karlsbad salts (powdered form) show this action to a greater degree.—H. K.

Carboligase. V. Union of carbon to carbon biosynthetically in the aliphatic series. J. Hirsch. Biochem. Zeits., 1922, 131, 178—187.

Yeast fermentation in the presence of pyruvic acid leads to the production of optically active methylacetylcarbinol. This "acyloin" condensation is brought about by the carboligase present in yeast.
—H. K.

Fer[illegible]tation; Production of the second and third forms of —— with Saccharomyces Saké, Zygosaccharomyces major, and Zygosaccharomyces salsus. H. Kumagawa. Biochem. Zeits., 1922, **131**, 148—156.

The Japanese yeasts named can decompose sugar according to the second and third modes of fermentation. *Saccharomyces Saké* can withstand a greater proportion of sodium bisulphite than German yeasts, thus giving rise to increased yields, 19·6% of acetaldehyde and 39·2% of glycerol, the alcohol production being only 10%.—H. K.

"Ropiness" in worts and beers; Causation of ——. P. Hampshire. Bull. Bur. Bio-Tech., 1922, No. 6, 179—187.

Application of the method previously described for the isolation of bacteria from beer deposits (J., 1922, 340 A) to a pitching yeast found to produce a ropy and highly acid wort after incubation for five days has resulted in the separation of an organism termed *Bacterium R*, which differs in cultural and physiological behaviour from that described by previous workers for organisms connected with ropiness. The character of the mucilage formed by *Bacterium R* in sterile beer is influenced greatly by the amount of oxygen available. In flasks from which the air had been expelled by means of either hydrogen or carbon dioxide, no surface film was formed on the beer, which retained its original slight turbidity but became permanently ropy. On the other hand, in presence of air a dense film appeared at the surface and a heavy slime at the bottom of the liquid, which also developed pronounced turbidity. A condition essential to the production of a typical clear ropiness is the presence of only a very limited amount of oxygen, the fact that the organism is able to induce this phenomenon when grown together with a yeast in the ordinary way being explained by the displacement of the air by the carbon dioxide resulting from the fermentation. A description is given of the morphological and physiological features of *Bacterium R*, which is compared with the members of the acetic acid group of bacteria or *Acetobacter*. The author is unable to confirm the obligate aerobic character of the latter organisms, which grow well in absence of oxygen, although the production of film is essentially an aerobic process.—T. H. P.

Citric and oxalic acids; Formation of —— in Citromyces cultures on sugar and a process for the quantitative estimation of these acids. W. Butkewitsch. Biochem. Zeits., 1922, **131**, 327—337.

Various kinds of citromyces were cultivated in 10% sucrose solutions deficient in nitrogen content, and calcium carbonate added. The citric and oxalic acids formed were estimated. In each case a large yield of citric acid was accompanied by a low yield of oxalic acid and *vice versâ*. This is attributed to the formation of oxalic acid at the expense of the citric acid. These two acids may be estimated in the presence of each other in an approximately quantitative manner either by extraction of the mixed calcium salts with dilute hydrochloric acid or by dissolving the salts in hydrochloric acid and precipitation of the calcium oxalate alone by addition of sodium acetate solution. The main error falls on the citrate.—H. K.

Citric acid; Utilisation and formation of —— in cultures of Citromyces glaber on sugar. W. Butkewitsch. Biochem. Zeits., 1922, **131**, 338—350.

Citric acid is formed by *Citromyces glaber* when grown either on normal or abnormal media. If citric acid be added to the nutrient media, oxalic acid appears directly. In dilute solutions the "economic coefficient" of the use of citric acid approaches that of dextrose, but in concentrated solutions it falls off. The combination of dextrose with citric acid is stimulative of the productive metabolism.—H. K.

Beer casks; American oak wood used in the construction of ——. P. Groom. J. Inst. Brewing, 1922, **28**, 645—677.

Beer casks made from American oak are classified as satisfactory or unsatisfactory according as they do not, or do, cause rapid deterioration, as regards taste and odour, of the beer contained in them. With casks of both classes investigations have been made, dealing with fungi and bacteria in the wood and beer, the presence or absence of sapwood, the mode in which the staves and end-pieces were cut, and the structure of the wood: its identification, porosity, and chemical constituents in so far as these are identifiable microchemically. The wood used was that described commercially as heartwood, although in many instances it was wood transitional between typical heartwood and sapwood, as it contained a considerable proportion of starch. All the wood used belonged to the most suitable class, that of the "white oaks." Three types agreeing largely with the wood of *Quercus alba* occurred regularly in both satisfactory and unsatisfactory casks; the latter contained a higher percentage of one of the three types and low percentage of doubtful pieces which could not be referred to any type. Tannin was always present in the walls of the constituents of the wood, which thus agreed with the heartwood of the two common European oaks. Starch was generally more abundant in unsatisfactory casks, but did not aid in the identification of the species and did not lead to deterioration of the beer by providing food material for fungi and bacteria in the wood, as such organisms were not found in staves or end-pieces. It is possible that wood may be unsatisfactory because it is from either an inappropriate species, or a tree felled at the wrong season, or heartwood that is too young. Generally the amount of calcium oxalate in the wood varied inversely as that of the starch. The bacteria found, termed tentatively *Clostridium*, *Streptothrix* and *Bacillus aceti*, occurred in the good and the bad beer in approximately equal numbers. Differences either in the artificial or natural seasoning in the country of origin, or in the pickling in this country, may possibly play a part in determining the satisfactory or unsatisfactory nature of the wood or cask.
—T. H. P.

Beer casks; Chemical examination of oaks used in the construction of ——. S. B. Schryver. J. Inst. Brewing, 1922, **28**, 678—696.

The proportions of extractives yielded to benzene, alcohol, and water by various timbers differ widely, but no correlation with the suitability of the timber for making beer casks is apparent. Beer is able to remove appreciable quantities of these extractives from the wood, especially during the first fortnight of contact; this removal occurs more readily with timbers satisfactory for making beer casks, than with those unsatisfactory. The various oaks examined showed wide variations (17 to 30%) in the amounts of matter removable by treatment with 4% sodium hydroxide solution, and there are distinct indications that the more satisfactory timbers yield more to this reagent than the unsatisfactory ones do. The differences between the various timbers as regards their value for cask-making appear to be due, not to any specific extractive imparting a deleterious flavour to the beer, but rather to fundamental differences in the physical and chemical properties of the timbers. The chief product extracted by alkali from American white oak is soluble in hot water to a solution which gelatinises on cooling, and has the properties of the hemicelluloses.—T. H. P.

Fusel oil from sweet-potato brandy. I. E. Yoshitomi, R. Soejima, and M. Imoto. Yakugakuzasshi (J. Pharm. Soc. Japan), 1922, No. 486, 661—666.

A SAMPLE of fusel oil from sweet-potato brandy, light brownish-yellow in colour, was fractionally distilled. The part distilling below 145° C. was composed of 46·5% of alcohol (or 10·5% of the original oil), 19·7% of water (4·45%), and 33·4% of amyl alcohol (7·79%). The residue boiling above 145° C. (10·6%) was saponified, and the presence of palmitic acid (5% of the oil) and lower fatty acids (1·77%) was detected. The acids are present as amyl esters in the oil.—K. K.

PATENTS.

Aeration of brewers' wort and other liquors; Process and apparatus for the ——. F. Bryant. E.P. 184,860, 18.5.21.

IN the normal methods of aeration, air is introduced at the bottom of the fermenting liquor and bubbles through and escapes freely at the top, resulting in considerable losses of the spirit produced. The modified process consists in introducing the air in the form of extremely minute bubbles, which are practically completely absorbed during their passage through the liquid. The apparatus consists of channels or chambers of porous stone or other foraminous material situated at the bottom of the fermenting vessel and into which air is led at a pressure above atmospheric, passing through the porous material into the surrounding liquor.
—W. H. G.

Butyl alcohol and acetone; Process for producing —— *by fermentation.* G. D. Horton, Assr. to E. I. du Pont de Nemours and Co. U.S.P. 1,427,595, 29.8.22. Appl., 6.9.19.

ACETONE and butyl alcohol are produced by fermenting a sterilised grain mash with *Bacillus acetobutylicum* without positively excluding sterilised air from the mash.—L. A. C.

Distilling process. Distilling apparatus. Apparatus for distilling. Process for distilling. E. J. Winter, Assr. to U.S. Industrial Alcohol Co. U.S.P. (A) 1,427,885, (B) 1,427,886, (C) 1,427,887, and (D) 1,427,888, 5.9.22. Appl., 13.6.18.

(A) AQUEOUS alcohol is distilled, the vapours being passed through a rectifier maintained under reduced pressure and at a temperature lower than the boiling point of absolute alcohol corresponding to the pressure used. The alcohol issuing from the top of the rectifying column is condensed. (B) Apparatus for working the above process, consisting of a still, and a long tubular rectifier with means for maintaining it at a predetermined temperature and under reduced pressure. (D) Aqueous alcohol of strength 20% or lower is distilled, the vapours being caused to come into contact with relatively moving bodies of mixed alcohol and aqueous condensate. The products from this separation are treated in a column rectifier. (C) A reduced pressure separator, in which vapours are constrained to follow a tortuous path, an unobstructed passage being provided for condensate. External means for refractionating the products in interconnected regions of a column rectifier maintained under reduced pressure are provided.—W. H. G.

Yeast; Process for making pressed —— *from beet juice.* F. Sailer. G.P. 355,596, 4.9.19.

THE juice is obtained by extracting the sliced beets in a diffusion battery. The juice coming from the first battery is passed through a second battery also filled with sliced beets. This has the effect of further enriching it with nutritive material which still remains in the raw material after the first diffusion and is of value for the preparation of yeast. The juice obtained is only slightly coloured. It contains, in addition to the sugar, the proteins and nutritive salts of the beet. The juice is subjected to the usual lactic fermentation after the addition of malt or malt-germs and is then sterilised. In addition to alcohol a pressed yeast of good quality can be obtained from it.—H. C. R.

[Fermentable] sugars from substances containing cellulose; Process for obtaining ——. A. Classen, Assr. to The Chemical Foundation, Inc. U.S.P. 1,428,217, 5.9.22. Appl., 21.6.19.

SEE E.P. 142,480 of 1920; J., 1921, 405 A.

Alcohol fuel. E.P. 184,607. *See* IIA.

XIXA.—FOODS.

Flour; Decomposition of hydrogen peroxide as a means of determining the degree of extraction of ——. D. Marotta and R. Kaminka. Giorn. Chim. Ind. Appl., 1922, 4, 249—251.

THE hydrogen peroxide test (*cf.* Marion, J., 1920, 796 A) has been applied to a number of flours of different origins and of 100, 90, 80, 70, and 60% extractions. The results show that, taken alone, this test gives no indication of the degree of extraction of a flour. Such an indication is, however, obtainable when the original grain is also available, since flours of various percentage extractions may then be prepared and the test applied to these also. In contact with hydrogen peroxide, flour from old or damaged grain yields little, if any, oxygen. Since such flour is also unsuitable for panification, it is possible that the catalase of flour exerts some function during this process.—T. H. P.

Flour; Determination of the acidity of ——. M. Arpin and M. T. Pecaud. Ann. Chim. Analyt., 1922, 4, 262—266.

MACERATION of the flour with 90% alcohol gives more regular results than maceration with water, as the alcohol prevents any further fermentation and gives the actual acidity at the time of sampling. The only two indicators found suitable were turmeric and phenolphthalein, of which the former gave the best results. Three series of experiments were carried out with three different kinds of flour to compare the results obtained. In each case both aqueous and alcoholic extraction were employed and the two indicators mentioned. The titrations were made with $N/50$ aqueous-alcoholic potassium hydroxide in the case of the alcoholic extract and aqueous potassium hydroxide in the case of the aqueous extracts. The maceration was continued for 19 days and tests carried out at intervals during this period. When alcoholic extraction was employed with turmeric as indicator, the acidity remained almost constant over the whole period. With phenolphthalein a slight increase in the values occurred. With aqueous extraction a very marked increase of acidity with the period of maceration occurred in all cases and the results obtained were much higher than in the case of alcoholic extraction. Carbon dioxide was evolved during the course of maceration with water.—H. C. R.

Corn [maize]; Characteristic proteins in high- and low-protein ——. M. F. Showalter and R. H. Carr. J. Amer. Chem. Soc., 1922, 44, 2019—2023.

A CONSIDERABLY larger part of the protein is present as zein and globulins in maize of high nitrogen content than in that of low nitrogen content;

the zein and globulins have been formed at the expense of the amides, albumin, and glutelin. The embryo constitutes about 15% of the total weight of maize corns of high nitrogen content, whereas Yellow Dent maize (low in nitrogen) of the usual composition has only about 11% of embryo. Zein is the protein present in most variable amount, averaging 50·28% in maize of high nitrogen content and only 31·85% in that of low nitrogen content. The protein of popcorn of high nitrogen content is particularly rich in zein, averaging 57·24%. The total nitrogen content appears to determine the amounts of the various proteins. The amino-nitrogen in the filtrate from the bases is higher in the maize of high nitrogen content than in that of low nitrogen content. The diamino acids constitute approximately twice as great a percentage of the total nitrogen in maize of high nitrogen content as in that of low nitrogen content.—H. W.

Milk; Physical and chemical changes of —— during pasteurisation. A. F. Weinlig. Forsch. Geb. Milchwirtsch. u. Molkereiwes., 1922, **2**, 127—169, 175—205. Chem. Zentr., 1922, **93**, IV., 593—594.

Equal quantities of milk were heated in round-bottomed flasks of 3 l. capacity, so that 800 c.c. of milk finally remained. The heating was carried out on the water-bath with occasional careful shaking. The time taken to warm up and cool down was not reckoned in the time of pasteurisation. The temperatures used were between 60° and 80° C. Careful pasteurisation accelerates the separation of cream, but if a certain temperature is exceeded the separation is delayed. This critical temperature depends on duration of heating. If the milk is only heated for a few seconds the critical temperature may be above 75° C., but if the duration of heating is ½ hr. the critical temperature is 63°—64° C. In judging the rate of separation, in addition to the amount of cream separating in 24 hrs., the fat content of the cream should also be determined. The fat content of the cream separating in 24 hrs. is at first decreased by increasing the temperature of pasteurisation, but does not usually fall as low as the value for raw milk. By further increase in the temperature of pasteurisation it is again markedly increased. These changes in the creaming of the milk are primarily caused by changes in the composition of the skin of albuminous colloid around the fat globules; the concentration and tenacity of this skin are increased by careful pasteurisation, but considerably diminished at higher temperatures. The viscosity of milk is decreased by pasteurisation at 60°—65° C., but less so by treatment at higher temperatures, and after treatment at 80° C. the viscosity usually exceeds the value for raw milk. The decrease is probably caused by changes in the casein, and the increase at higher temperatures by vaporisation of water, coupled perhaps with changes in the albumin. A definite influence on the sp. gr. of milk could not be ascribed to pasteurisation. The acidity of milk is reduced by pasteurisation, but to different degrees in different samples. The albumin content of the milk is strongly influenced by the temperature and duration of pasteurisation. By treatment at 60° C. for ½ hr. on an average 8·5% of the soluble albumin becomes insoluble, but the amount varies greatly from sample to sample. By treatment at 80° C. for 1 min. 40% of the soluble albumin became insoluble. The decomposition of the casein is illustrated by the altered behaviour of milk on the addition of rennet. Milk treated at 60° C. for ½ hr. has its coagulation by rennet delayed by 10·2%, while the time of coagulation of milk treated at 80° C. for 1 min. is increased by 32·6%. The changes in the casein are partly due to the precipitation of calcium and magnesium salts.—H. C. R.

Rennet; Chemical action of ——. G. S. Inichoff. Biochem. Zeits., 1922, **131**, 97—108.

On addition of rennet to milk or casein solutions under various conditions, there is no appreciable increase of acidity. Peptonisation does not therefore occur. The action of rennet is purely physical, the formation of paracasein being due to a change in the degree of dispersity of the solution under the influence of the enzyme and in presence of divalent ions and hydrogen ions.—H. K.

Margarine; Water-content of ——. K. Brauer. Chem.-Zeit., 1922, **46**, 834.

The determination of the water-content of samples of margarine taken from different parts of the same packets shows that enormous variations occur. Samples taken from the outside of the packet often contain as much as 7% less water than samples taken from the middle of the same packet. It follows that only analyses based on average samples taken from a whole packet can be of any value. The low water-content of the outer layers is ascribed to evaporation and absorption of water by the paper wrappings.—H. C. R.

Antineuritic vitamin; Further experiments on the isolation of the ——. A. Seidell. J. Amer. Chem. Soc., 1922, **44**, 2042—2051. (*Cf.* Seidell, J., 1922, 191 a.)

The preparation of the vitamin solution is modified in that, instead of subjecting the fresh yeast to autolysis and filtering the thick, slimy liquid thus obtained, the yeast is treated for a few minutes with boiling water and the mixture is then centrifuged. The aqueous solution thus obtained contains a greater proportion of the total vitamin than is present in the filtrate from autolysed yeast and, in addition, is free from adenine and other products of autolytic decomposition. The vitamin is adsorbed from its acid solution by fuller's earth (*cf.* Seidell, U.S. Pub. Health Repts., 1922, **37**, 801) thus giving an activated solid which is extracted with barium hydroxide solution and the barium eliminated by addition of sulphuric acid. The extract is treated with saturated lead acetate solution and filtered. The filtrate is freed from excess of lead by means of hydrogen sulphide and concentrated by distillation under diminished pressure (the treatment with lead acetate prevents the otherwise excessive foaming during distillation). The residue is precipitated successively with silver nitrate and ammoniacal silver nitrate. Approximately one-third of the solids of the extract is precipitated as silver compounds and these contain somewhat more than one-half of the antineuritic vitamin. The incomplete precipitation of the vitamin is attributed to the considerable solubility of its silver compound. The vitamin fractions are quite stable both in solution and in the dried condition. They dialyse almost completely through a collodion membrane and physiological tests show that all of the vitamin is in the diffusate, thus indicating that the vitamin molecule is of relatively simple constitution. Using nitrogen estimations as a criterion of purity, the conclusion is drawn that the highly active fractions contain vitamin and one or more analogous nitrogenous bases and that these cannot be separated advantageously from one another by silver precipitation.—H. W.

Vitamin B; Preparation and properties of ——. S. Tsukiye. Biochem. Zeits., 1922, **131**, 124—139.

The author has prepared an active vitamin B preparation from an 80% alcoholic extract of 30 kg. of rice polishings and from an aqueous extract of 4 kg. After purifying with basic lead acetate, the vitamin is precipitated by phosphotungstic acid, the precipitate decomposed by baryta, and the silver precipitate obtained in acid solution removed. Baryta is added till the solution is weakly alkaline and the precipitate containing the vitamin collected and freed from silver. The vitamin is precipitated by tannin and picric acid and the picrate is soluble in alcohol and hot water. The vitamin is not soluble in the neutral state in alcohol above 80% strength, but is easily soluble in acidified alcohol or water.—H. K.

Amino-acid nitrogen. Riffart. *See* XXIII.

Patents.

Fat-containing granular products; Process for rendering —— impalpable. J. Eppenberger. E.P. 176,305, 14.4.21. Conv., 1.3.21.

Granular products containing fat, such as almonds, coffee beans, cocoa beans, and the like, are fed from a hopper into a disintegrator consisting of two rotating rollers of which one can move away resiliently from the other to allow large pieces of material to be drawn between. The material then falls by gravity through a series of smooth rollers in pairs so driven that the two rollers in each pair rotate at different velocities. To reduce the number of rollers required, these may be vertically staggered and so arranged that each roller, except the highest and lowest, by contact with the rollers immediately above and below it, provides two grinding passes. The rollers have a surface which is either fluted or sufficiently porous to grip the material and draw it between them. The temperature of the rollers is raised by the friction between their surfaces, and can be adjusted as desired by admitting steam or water into the rollers through the hollow axes. Adhering particles are removed from the rollers by scrapers, and means are provided for adjusting the pressure between each pair of rollers.—L. A. C.

Milling flour; Method for use in ——. A. W. Woolcott. E.P. 184,837, 18.4.21.

The stock during its reduction from wheat to flour is subjected to moistened air supplied in separate streams to individual machines used in the milling operation, the moisture content of the air being independently regulated in the various streams. The air may be first purified and its temperature may be regulated. Nitrogen peroxide, chlorine, or the like may be added to the air.—H. C. R.

Whey; Process for the extraction of proteids and lactose from ——. D. Thomson. U.S.P. 1,428,820, 12.9.22. Appl., 12.12.21.

See E.P. 173,831 of 1920; J., 1922, 192 A. After neutralising the whey as described, more alkali is added till an alkalinity corresponding to p_H 10·5 is attained, after which the solution is evaporated, the remaining protein coagulated and separated, and lactose recovered by crystallisation.

Vegetable proteid substances; Process of manufacturing ——. S. Satow. U.S.P. 1,427,645, 29.8.22. Appl., 20.8.18.

See E.P. 121,141 of 1917; J., 1919, 263 A.

Sterilising and filling of receptacles with substances such as milk or alimentary liquids; Method of and apparatus for ——. Sterilising milk. N. J. Nielsen. E.P. 185,185, 26.5.21, and 185,221, 31.5.21.

Margarine; Manufacture [consolidating and blending] of ——. Maypole Margarine Works, Ltd., and O. Michelsen. E.P. 185,241, 8.6.21 and 7.1.22.

XIXb.—WATER PURIFICATION; SANITATION.

Lime-sulphur [insecticidal] mixture; Studies on ——. C. Harukawa. Ber. Ohara Inst. Landw. Forsch., 1921, 2, 1—20.

Mixtures containing lime and sulphur in the proportions of 1:1 and 1:2 respectively were compared. Spraying experiments against scale insects showed no difference in effectiveness where quantities of the sprays containing equal amounts of sulphur were used. The reducing power towards permanganate solutions was the same with both sprays. It was noted that in all cases the amount of permanganate reduced at ordinary temperature was one half that reduced in boiling solutions. Lime-sulphur mixture does not possess the power of dissolving the wax of the scale insect. After death of the insect the activity of the oxidase and catalase of the tissue gradually decreases. Living as well as dead scale insects fall from infected trees after spraying with lime-sulphur. The death of the insect may be judged by the change of colour of the insect within a definite time after spraying.
—A. G. P.

Pyrethrum [insecticide] powder. D. Costa. Giorn. Chim. Ind. Appl., 1922, 4, 251—253.

For the determination of the water-soluble extract in finely ground commercial insecticide powder from *Chrysanthemum cinerariaefolium*, the author uses a cylindrical separating funnel, in which are placed, in order, layers of cotton-wool, powdered pumice, powdered pumice mixed with the insecticide, pumice, and cotton-wool. Two hundred c.c. of water is poured slowly into the funnel, 100 c.c. of extract being drawn off and replaced by water after 12 hours; the extraction is complete after two repetitions of this treatment. The percentage of water-soluble extract, calculated on material dried at 100° C., is 22—25, 12—14, and 9—11 for closed flowers, open flowers and stems of pyrethrum respectively.—T. H. P.

Patents.

Sewage; Treatment of —— in underdrained settling basins. K. Imhoff. E.P. 184,742, 19.12.21.

Sewage sediment deposited in basins with an underdrained bottom is dried rapidly and without odour by using only a shallow depth of liquid, *e.g.*, about the same as the thickness of the final layer of the sludge, *i.e.*, 4—12 ins. Preferably a number of basins are so arranged that sewage can be run into one at a time, the one in use being baffled to hold back the sediment. Sufficient sewage to deposit the desired depth of sludge is run through the basin with the drain pipe closed, and the overflow passes through another basin. As soon as sufficient sludge is deposited in the first basin, the drain pipe is opened and the sludge is allowed to drain and dry, the supply of water being diverted to the basin which previously received the overflow.
—L. A. C.

Removing oxygen from liquids; Process and apparatus for ——. Union Thermique. E.P. 181,309, 7.9.21. Conv., 8.6.21.

A tank is provided with a horizontal perforated diaphragm on which is placed deoxidising material (*e.g.*, iron filings) and is also provided with vertical non-perforated diaphragms which extend from the horizontal diaphragm alternately to the bottom and top of the tank, so that when water is admitted to one side of the tank and exhausted at the other, it will pass through the deoxidant several times. The spaces above the horizontal diaphragm are left quite large so as to form storage chambers for a reserve of partly treated water, and the top of the tank is covered and provided with removable water-sealed caps for access to the interior. Cleaning jets may be provided within the tank for cleaning the deoxidant and removing sediment.—B. M. V.

Fungicide and insecticide. Farbenfabr. vorm. F. Bayer und Co. G.P. 355,829, 16.4.15. Addn. to 349,870 (J., 1922, 516 A).

Ethers of hydroaromatic alcohols, such as cyclohexyl methyl ether, with or without other additions (*cf.* G.P. 349,871; J., 1922, 516 A) are used. These ethers can be used either in the liquid state or in the form of vapour, or in the same way as the hydroaromatic ketones, such as cyclohexanone, specified in the main patent.—H. C. R.

Sterilising air; Method of ——. A. Wolff. U.S.P. 1,423,704, 25.7.22. Appl., 3.11.20.

See G.P. 346,201 of 1921; J., 1922, 230 A.

Refuse destructor furnaces. J. S. Atkinson, and Stein and Atkinson, Ltd. E.P. 185,492, 2.6.21, 20.7.21, 2.3.22.

Base-exchanging bodies. E.P. 159,196. *See* VII.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Meconic acid; Estimation of —— *in opium.* H. E. Annett and M. N. Bose. Analyst, 1922, 47, 387—391.

Five grms. of opium is triturated with 50 c.c. of water, and after standing overnight, 40—45 c.c. of the filtered liquid is treated with 6 c.c. of 50% calcium chloride solution and allowed to stand for a further 24 hours. The precipitate, consisting of calcium meconate and sulphate, is filtered off, washed till the washings are colourless, and dissolved in 15 c.c. of 1·25 *N* hydrochloric acid. After standing for 24 hours pure meconic acid will have separated in white scales. It is filtered off, washed twice with 0·5 c.c. of distilled water, dried over sulphuric acid, and weighed as $C_7H_4O_7,3H_2O$. To the weight found 0·0213 g. is added to correct for the solubility of meconic acid in 15 c.c. of 1·25 *N* hydrochloric acid, and the figure obtained is multiplied by the factor depending on the amount of the aliquot portion of the solution taken for analysis, and then by the factor 10/9, to correct for the amount of meconic acid unprecipitated by calcium chloride. —G. F. M.

Cevadine. I. A. K. Macbeth and R. Robinson. Chem. Soc. Trans., 1922, 121, 1571—1577.

Cevadine, $C_{32}H_{49}O_9N$, has already been shown to be the tiglate of an alcohol, cevine, $C_{27}H_{43}O_8N$. The presence of a second hydroxyl group in cevine has now been demonstrated by the preparation of *o*-nitrobenzoylcevadine and di-*o*-nitrobenzoylcevine. In the hydrolysis of cevadine with potassium hydroxide the cevine is obtained as a potassium salt, from which cevine was isolated by passing carbon dioxide through the aqueous solution. The formation of this salt probably points to the presence of a lactone ring in cevine, as this substance exhibits no phenolic character. Cevine is lævo-rotatory $[\alpha]_D^{17} = -15·36$ (in methyl alcohol). By distillation with soda-lime in a stream of hydrogen a small yield of a base which appeared to be identical with *l*-coniine was obtained.—G. F. M.

Elsholtzic acid; Constitution of ——. Y. Asahina and S. Kuwada. Yakugakuzasshi (J. Pharm. Soc. Japan), 1922, No. 485, 565—579.

Furane-2-methyl-3-carboxylic acid, prepared by the method of Benary (Ber., 1911, 44, 493), was oxidised by the method of Hill and Sawyer (Ber., 1894, 27, 1569) to furane-2.3-dicarboxylic acid, colourless prisms, m.p. 221° C. The latter gave a dimethyl ester, white crystals, m.p. 34° C., and a monoanilide, light yellowish-brown needles, m.p. 169°—170° C., and was identical with the acid obtained from elsholtzic acid, the constitution of which is therefore furane-3-methyl-2-carboxylic acid.—K. K.

Heliotropin; Preparation of —— *from isosafrol by means of ozone.* S. Nagai. Kôgyô-Kwagaku Zasshi (J. Chem. Ind. Japan), 1922, 25, 631—652.

The author has studied the ozonisation of isosafrol by ozonised air containing 2—3·5% of ozone, the decomposition of isosafrolozonide, and the preparation of heliotropin. The ozonide is easily prepared by passing ozonised air into a solution of isosafrol (10 g.) in a perfectly dry solvent (100—150 g.), such as carbon tetrachloride, tetrachloroethane, chloroform, glacial acetic acid, toluene, or xylene. The product is separated by distilling off the solvent *in vacuo*, or by diluting with 2—3 vols. of petroleum ether having nearly the same boiling point as the solvent. When a mixture of 1 vol. of the solvent and 2—3 vols, of petroleum ether is used, the ozonide produced is precipitated and the process may be made nearly continuous by adding isosafrol from time to time. The ozonide, a deep reddish-brown, viscous oily substance having a characteristic odour, is easily decomposed at the ordinary temperature and by warming its solution at 40°—50° C., or stirring it with water, the products being acetaldehyde, heliotropin, piperonylic acid, and a dark brown resinous substance. When the ozonide solution is stirred with excess of 35—36% sodium bisulphite solution, the ozonide is decomposed by water, the freed oxygen is reduced by the reagent, and the heliotropin produced separates as a crystalline addition product, the yield being 85%. —K. K.

Silver-albumose; Estimation of silver in ——. G. Maue. Pharm. Zeit., 1922, 67, 751—752.

The method previously given (J., 1918, 782 A) is not always applicable owing to variations in the quality of commercial silver-albumose preparations. The following process is now recommended. 1 g. of silver-albumose is dissolved in 5 c.c. of water and 5 c.c. of nitric acid (sp. gr. 1·4) and heated to boiling until a clear solution is obtained. After cooling 35 c.c. of potassium permanganate solution (1:20) is added in small portions and the solution again boiled over a small flame. After boiling for 15 mins. the solution is decolorised by sufficient powdered oxalic acid, diluted with 50—100 c.c. of water and titrated with *N*/10 ammonium thiocyanate solution, using ferric ammonium sulphate solution as indicator.—H. K.

Silver-albumose; Estimation of silver in ——. J. Herzog. Pharm. Zeit., 1922, 67, 802—803. (*Cf. supra.*)

One grm. of the silver-protein complex is dissolved in 10 c.c. of water and 10 c.c. of strong sulphuric acid added in a thin stream. 2 g. of finely divided potassium permanganate is then added gradually with vigorous shaking. After keeping for 15 mins., the solution is diluted with 50 c.c. of water and the excess of permanganate or peroxides of manganese removed by addition of small portions of ferrous sulphate. Ferric ion is thus formed which acts as indicator in the subsequent titration with *N*/10 ammonium thiocyanate solution.—H. K.

Hexamethylenetetramine; Catalytic synthesis of ——. L. E. Rombaut and J. A. Nieuwland. J. Amer. Chem. Soc., 1922, 44, 2061.

Hexamethylenetetramine is formed in small amount when a mixture of carbon monoxide,

hydrogen, and ammonia at atmospheric pressure is passed over a mixture of equal parts of reduced, finely-divided nickel and very pure diatomaceous earth heated to 250°—280° C. A trace of ammonium cyanide and a relatively large quantity of ammonium carbonate are also produced, the latter resulting from the reaction, $2CO \rightarrow C + CO_2$, since a deposition of carbon is noticed in the reaction chamber. The effectiveness of a catalyst in this synthesis depends on its ability to form an unstable carbonyl, for reaction does not occur when the nickel catalyst is replaced by platinised asbestos.
—H. W.

Butadiene; Formation of —— from ethylene. J. E. Zanetti, J. R. Suydam, jun., and M. Offner. J. Amer. Chem. Soc., 1922, **44**, 2036—2041.

The formation of butadiene from ethylene has been studied at temperatures varying from 550° C. to 850° C. The temperature of maximum formation is 750° C., above which the decomposition of ethylene into methane, hydrogen, and carbon occurs very rapidly. The maximum quantity of ethylene transformed into butadiene is 0·0096 litre per litre of ethylene. It is suggested that the formation of aromatic hydrocarbons from ethylene takes place, in part at least, through the intermediate production of butadiene. Attention is directed to the formation of an aliphatic hydrocarbon of higher boiling point from one of a lower boiling point and to the possible rôle of similar reactions in the cracking of oils.—H. W.

Alcohols; Electrolytic oxidation of ——. I. Isoamyl alcohol. S. Koizumi. Mem. Coll. Sci. Kyoto Imp. Univ., 1922, **5**, 359—382.

The material used in the investigation had b.p. 130°—132° C., sp. gr. 0·811, and was obtained by the fractional distillation of technical isoamyl alcohol; it possibly contained a small quantity of optically active amyl alcohol. The experiments were made in a divided cell, the cathode being of nickel gauze or sheet lead and the cathode solution being sulphuric acid or dilute aqueous sodium hydroxide. Lead peroxide acted most effectively as anode material. The products of the oxidation were isovaleric acid, isovaleraldehyde, and carbon dioxide. In alkaline solution the acid formed was always accompanied by the aldehyde; the current efficiency increased with decreasing current density. In sulphuric acid solution, aldehyde was produced only when the current density fell below 1 amp. per 100 sq. cm. For the electrolytic preparation of isovaleric acid the most suitable current density was 1—1·4 amp. per sq. dcm. if the solution remained stationary and about 2 amp. per sq. dcm. when it was stirred. The most favourable concentration of sulphuric acid was 10—20%. The temperature should be maintained below 30° C. Vanadium pentoxide, cerium sulphate, potassium bichromate, and ferrous sulphate were found to be effective oxygen carriers. A convenient and rapid electrolytic method for preparing isovaleric acid without involving the use of a diaphragm is described in detail.
—H. W.

Formic acid; Catalytic decomposition of ——. E. Müller. Z. Elektrochem., 1922, **28**, 307—310.

The catalytic decomposition of formic acid in solution into carbon dioxide and hydrogen by finely-divided rhodium as observed by Deville and Debray in 1874 was found to be due to impurities in the rhodium, most probably osmium. The decomposition takes place rapidly with osmium reduced from the hydrated dioxide by hydrogen at 150° C.; thus, 0·3 g. of the metal in 10% formic acid solution containing 3·4% of sodium formate causes the evolution of 2 c.c. of gas per second, the liquid eventually becoming alkaline due to the decomposition of the sodium formate into sodium carbonate and hydrogen. Any conditions that tend to cause the osmium to become colloidal increase its activity, while the higher the metal has been heated the less active it becomes. Neither pure rhodium nor pure platinum have any action, but the addition of very small quantities of osmium to either metal imparts a considerable catalytic activity.—A. R. P.

Piperitone; Position of the double linkage in ——. II. A. R. Penfold. Perf. Essent. Oil Rec., 1922, **13**, 322—323.

From the products of the oxidation of piperitone with neutral potassium permanganate, in addition to diosphenol, the following acids were isolated: α-hydroxy-α-methyl-α-isopropyladipic acid, m.p. 143·5° C., α-isopropyl-γ-acetylbutyric acid, identified by its semicarbazone, m.p. 158° C., and α-isopropylglutaric acid, m.p. 94°—95° C. The formation of these substances confirms the constitution of piperitone previously put forward, viz., Δ_1-menthenone-3. The best method for the preparation of piperitone hydroxylamino-oxime consists in treating a cold alcoholic solution of the ketone with hydroxylamine hydrochloride in presence of potassium hydroxide. After keeping for a few hours the whole solidifies to a crystalline mass of the oxime in quantitative yield.—G. F. M.

Geraniol content of citronella oil; Determination of the so-called total ——. A. W. K. de Jong and A. Reclaire. Perf. Essent. Oil Rec., 1922, **13**, 319—321.

Numerous samples of citronella oil were analysed by slightly varying methods in order to ascertain the reason for the different results often obtained by different operators. The maximum difference observed was 2·8%, the average difference 0·7%. The influence of acetic anhydride of higher concentration than usual (80%) was negligible, and sodium acetate dried over sulphuric acid did not give better results than the usual re-fused material. The method recommended is to heat 10 g. of the oil, 10 c.c. of 80% acetic anhydride, and 2 g. of sodium acetate for 2 hrs. After cooling, 50 c.c. of water is added, and the excess of anhydride is decomposed by warming and shaking. The acetylated oil is separated, washed with brine until neutral, and dried. About 1·5 g. is then saponified with *N*/2 alcoholic potassium hydroxide, after neutralising any residual acidity. After boiling for 2 hrs. under a reflux condenser the excess of alkali is titrated back with *N*/2 sulphuric acid.—G. F. M.

Sandalwood oil; Properties and preparation of Dutch East Indies ——. A. Rojdestwensky. Perf. Essent. Oil Rec., 1922, **13**, 331—332.

The amount of oil obtainable from Dutch East Indian sandalwood varies from 3·8 to 5·8%. The oil has the following characters:—Sp. gr. at 15° 0·9745—0·9842, $\alpha_D^{28} = -16·4°—18·4°$, santalol content 93·7—98%, soluble in 3—4 vols. of 70% alcohol, $n_D^{28} = 1·5000—1·5013$. The quantity of oil obtainable from a sample of the wood may be ascertained by distilling not more than 0·5 kg. of shavings with water after soaking for 48 hours. After 10—15 hrs. the colour of the oil begins to darken, and after 20 hrs. the distillation is finished. The earlier and later runnings of oil do not differ greatly in properties. For the distillation of larger quantities the wood is cut into pieces about the size of oats, and a steam-jacketed stirring apparatus is employed, saturated steam being blown slowly through the wood.—G. F. M.

Essential oil from Cinnamomum glanduliferum. V. Massera. Riv. It. Essenze e Profumi., 1922, **4**, 41—42. Chem. Zentr., 1922, **93**, III., 502.

From 30 kg. of leaves and twigs there was obtained

180 g. of oil, which was yellow in colour and had a camphor-like odour. The oil had sp. gr. at 15° C., 0·9024; $\alpha_D^{20} = -23° 20'$; $n_D^{20} = 1·4685$; saponif. value, 11·16; acetyl value, 39·76; soluble in 4·5 times its weight of 80% alcohol. Its constituents are pinene and camphene (which, however, could not be confirmed by the preparation of derivatives), cineol (34·2%), and *l*-α-terpineol (about 10%).—H. C. R.

Patents.

Acetaldehyde; Production of —— from acetylene. Soc. Anon. de Prod. Chim. Etabl. Maletra. E.P. 165,085, 19.5.21. Conv., 15.6.20. Addn. to 140,784 (J., 1921, 716 A).

In the synthetic production of acetaldehyde from acetylene in the presence of a mercury catalyst in an acid medium, and of a ferric salt to maintain the catalytic action of the mercury as described in the main patent, the exhausted reaction liquid is regenerated by anodic oxidation after the removal of dissolved acetaldehyde and mercury salts, which would otherwise cause inconvenience owing to amalgamation and disintegration of the lead anodes. The mercury salts are removed from the reaction liquor by means of iron filings, preferably at a temperature not exceeding 70° C. The mercury is deposited at the bottom of the receptacle and the liquid is decanted. The aldehyde is removed by distillation in a vacuum at a temperature not exceeding 50° C., in order to avoid polymerisation to tarry products.—G. F. M.

Compositions of oils or other organic substances; Manufacture of ——. Plauson's (Parent Co.), Ltd. From H. Plauson. E.P. 184,534, 11.4.21.

Transparent, colloidal dispersions of essential oils in non-solvents, such as water or glycerin, for use, *e.g.*, as perfumes or flavouring essences, are prepared by treating a mixture of an oil and a large quantity of the non-solvent for several minutes in a colloid mill, such as that described in E.P. 155,836 (J., 1922, 357 A), in the presence of a substance capable of accelerating dispersion. Suitable substances are oil solvents which are wholly or partially miscible with water, such as ketones, alcohols, or esters (*e.g.*, acetin), or substances containing one or more sulphonic groups, such as Turkey-red oil, sulphonaphthenic acids, or purified sulphite-cellulose waste liquor. In preparing perfumes, the odour is improved by the addition of a small quantity of ambergris before treatment in the mill. The dispersions may be converted into concentrated emulsions or gels by ultra-filtration by the process described in E.P. 155,834 (J., 1922, 619 A), or similar concentrated products can be obtained by treating a relatively large quantity of oil with the non-solvent.—L. A. C.

Oxalic acid; Manufacture of ——. J. Y. Johnson. From Badische Anilin- und Soda-Fabr. E.P. 184,627, 7.6.21.

Oxalic acid is prepared by treating wood or other cellulosic material with nitric acid, or nitrous gases and water, in the presence of compounds, *e.g.*, nitrates, of iron, or of the rare earths, or of magnesium. For example, wood is steeped in nitric acid of up to about 65% strength containing, *e.g.*, 2 to 4% of iron as iron nitrate, or didymium or didymium-lanthanum salts, and is treated below 70° C. with a stream of nitrous gases such as those obtained by the catalytic oxidation of ammonia. The product is filtered and cooled, crystals of oxalic acid are separated, and the mother liquor is used for treating a fresh quantity of wood. If magnesium compounds are employed, the reaction is effected at a higher temperature, *e.g.*, finely divided wood is added gradually with vigorous agitation to fused crystalline magnesium nitrate at 160°—170° C., the nitric acid liberated from the magnesium nitrate effecting oxidation of the wood. Alternatively, the wood may be added to other fused magnesium salts, such as the chloride, maintained at about 170°—190° C., sufficient nitric acid to oxidise the wood being added subsequently. The melt is dissolved in dilute nitric acid, and the solution is either cooled to effect crystallisation of the oxalic acid, or the oxalic acid is precipitated as its calcium salt.—L. A. C.

Pharmaceutical compounds. H. Weyland, H. Hahl, and R. Berendes, Assrs. to Farbenfabr. vorm. F. Bayer und Co. U.S.P. 1,427,182, 29.8.22. Appl., 8.8.21. (*Cf.* J., 1922, 786 A.)

A pharmaceutical product, useful as a remedy against scabies, is obtained by the interaction of toluene, sulphur, and aluminium chloride. It is a yellowish oil, b.p. 150°—230° C. at 3 mm. pressure, and it contains 23—25% of sulphur.—G. F. M.

Salicylaldehyde; Process of producing ——. C. C. Loomis, Assr. to Semet-Solvay Co. U.S.P. 1,427,400, 29.8.22. Appl., 23.6.21.

Salicylaldehyde is formed in presence of an alkali sulphite or bisulphite in such excess as to convert the aldehyde, as it is formed, into a bisulphite addition product, from which, after completion of the reaction, it is regenerated by distillation.—G. F. M.

Hydrocarbons of the terpene series; Process for preparing polycyclic ——. Chem. Fabr. auf Actien (vorm. E. Schering). G.P. 353,933, 12.8.20.

Hydrazones of terpene ketones are heated with mercuric oxide in indifferent solvents. Alternatively the double salts of the hydrazones with mercuric chloride are heated in indifferent solvents after the addition of the equivalent quantity of alkali hydroxide. The action of mercuric oxide on the hydrazones produces basic mercury compounds, soluble in water, which on heating in indifferent solvents decompose according to the equation

$$C_{10}H_{16}:N.NH.Hg.OH = C_{10}H_{16} + N_2 + Hg + H_2O.$$

Tricyclene, obtained from camphor-hydrazone and mercuric oxide in alcohol by boiling for 8 hrs., distilling off the alcohol and precipitating with water, has b.p. 153·5° C., m.p. 63·5° C. *d*-Cyclofenchene, from α-fenchone-hydrazone, has b.p. 142·5°—143·5° C., sp, gr. at 20°/4° C. 0·8588, $n_D^{20} = 1·45134$, $[\alpha]_D^{20} = +0·45°$. Apocyclene, from camphenilone-hydrazone, has b.p. (17 mm.) 120·5° C., b.p. 138°—139° C., m.p. 40·1° C., sp. gr. at 45°/4° C. 0·8694, $n_D^{20} = 1·44914$.—H. C. R.

Hydrocoumarins and their derivatives; Process for preparing ——. Tetralin Ges.m.b.H. G.P. 355,650, 9.5.20.

o-Coumaric acid or a substitution product, salt, ester or lactone thereof is treated with hydrogen under pressure and at temperatures not exceeding 200° C. in the presence of nickel catalysts. The usual nickel catalysts activated with small quantities of copper are suitable, or combinations of nickel catalysts with another metal or metallic oxide of the iron group in conjunction with a heavy metal or metallic oxide not belonging to this group, may be used. Examples are given of the hydrogenation of 1.2-coumarin to *o*-hydrocoumarin, of *o*-coumaric acid to *o*-hydrocoumaric acid, which can be converted by distillation into hydrocoumarin, and of the hydrogenation of *o*-methoxycinnamic methyl ester to *o*-methoxyhydrocinnamic methyl ester. The products can be utilised as perfumes and as intermediates in the manufacture of dyestuffs and medicines.—H. C. R.

Nitroamines; Preparation of aromatic ——. L. Haas, Assr. to Soc. Chim. de la Grande Paroisse. U.S.P. 1,423,494, 18.7.22. Appl., 2.9.21.

See E.P. 169,688 of 1921; J., 1922, 647 A.

Dialkyl sulphates; Process of manufacture of ——. L. Lilienfeld. U.S.P. 1,427,215, 29.8.22. Appl., 10.1.21.

See E.P. 143,260 of 1920; J., 1921, 322 A.

Acetaldehyde; Production of —— *from acetylene.* L. E. M. Trevoux, Assr. to Soc. Anon. Prod. Chim. Etabl. Maletra. U.S.P. 1,428,668, 12.9.22. Appl., 31.5.21.

See E.P. 165,085 of 1921; preceding.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Colouring matters; Formation of —— *by oxidation with exposed silver halides.* R. Fischer and H. Siegrist. Phot. Korr., Jan., 1914. Bull. Soc. Franç. Phot. 1922, 9, 247—249.

By employing paraphenylenediamine and its derivatives as developers in the presence of phenols as combining substances, colour images are obtained on dissolving away the reduced silver. With dichloronaphthol the colours obtained are:—On development with paraphenylenediamine—bluish-pink; with paratoluylenediamine—blue; with dimethylparaphenylenediamine—bluish-green. Phenol itself and its halogen derivatives give colours varying from blue to green, but which are not fast. Combinations of aromatic nitroso compounds with substances containing an acid methyl group give a large variety of tones by forming azomethines. Non-cyclic organic compounds containing the double carbon linkage, such as allyl alcohol and cinnamic acid, give with sulphite very rapid coloration. Essential oils of lavender, bergamot, geranium, orange, etc. act similarly. On the other hand, some substances, such as phenol, catechol, tannic acid, picric acid, naphthol, etc., containing hydroxyl groups in the benzene nucleus, act by diminishing the sensitiveness.—W. C.

Colouring matters; Reduction of —— *by light.* R. Ihran. Phot. Korr., Dec., 1913. Bull. Soc. Franç. Phot., 1922, 9, 249—250.

A résumé of work on the action of light on colouring matters in presence of sodium sulphite and an organic compound such as thiosinamine or anethol. The action of sulphite is variable. Some colours like Fuchsin, Malachite Green, Alkaline Blue, etc. are immediately decolorised; others, like Methylene Blue, are very slowly decolorised and exposure to light has no marked effect. The presence of organic materials modifies the action, and contact with paper is sufficient to render the treated colour very slowly sensitive to light. Colouring matters like Erythrosine and Rose Bengal do not change in the dark in the presence of sulphite, but are decolorised in light in the presence of organic compounds. A fourth group of colours, such as nitro- and azo-dyes, are not changed by sulphite in the dark nor in the light. Colours which bleach rapidly in light under the action of an organic-sulphite compound belong to two groups, *i.e.*, thiazines, such as Methylene Blue, and Toluidine Blue, and Eosines, such as Eosine, Erythrosin, Rose Bengal, and Fluorescein. The colours obtained with *p*-nitrobenzyl cyanide with various developers are: With *p*-phenylenediamine—yellowish; with dimethyl-*p*-phenylenediamine—reddish-blue; with diethyl-*p*-phenylenediamine—bluish-red. The colours obtained are not very fast to light, but are fairly stable in diffused light if the reduced silver is not removed.—W. C.

Isocyanines; Brominated ——. K. L. Moudgill. Chem. Soc. Trans., 1922, 121, 1509—1511.

Comparison by the photographic method of Pinacyanol (1.1′-diethylazurine iodide) and its 6.6′- and 5.5′ (or 7.7′)-dibromo-derivatives shows that the introduction of the halogen into the quinaldine nucleus considerably depresses the sensitiveness, which at the same time is shifted towards the red end of the spectrum.—G. F. M.

Cyanine dyes. Mills and Braunholtz. *See* IV.

Patents.

Cinematograph films; Process for coating the surface of ——. A. F. M. Ott. E.P. 184,495, 10.3.21.

The film surface is coated with a mixture of collodion, ether, methylated spirit, and formic acid, and then dried. A suitable proportion for the ingredients is 100 c.c. of collodion (4% in ether-alcohol), 500 c.c. of ether (sp. gr. 0·72), 500 c.c. of methylated spirit (90—96%), and 30 c.c. of formic acid (80%). Formic acid may be replaced by glacial acetic acid or ethyl acetate. This treatment increases the life of the film and protects the surface from scratching. It also increases the pliability of the film and strengthens it against wear at the sprocket holes.—W. C.

X-ray photography; Sensitive film supports for ——. N. E. Luboshey. E.P. 184,519, 2.3.21.

The sensitive emulsion is coated on one or both sides of a support prepared by incorporating a material such as gelatin, glue, gum, celluloid, or collodion with substances such as calcium tungstate, barium platinocyanide, etc., which are used in making intensifying screens for X-rays.—W. C.

Photographic emulsions; Process for intensifying the action of X-rays on ——. C. Schleussner. G.P. 356,378, 28.12.20.

Secondary rays are produced by using salts of those organic or inorganic residues which are capable of dyeing silver bromide either by bathing or addition to the emulsion in the silver bromide complex, their "atomic weights" depending on the object to be attained. For example, an emulsion can be treated with a 1% solution of the strontium salt of Tetrabromofluerescein, or the finished plates may be bathed in a 0·2% solution of this salt.—W. C.

Photographic print-out images; Toning process for ——. Graphikus-Ges. m.b.H. G.P. 356,380, 29.5.19.

Sulphide toning baths are used after previous use of two fixing baths. Selenium toning baths may be applied after the sulphide toning. By using the selenium toning baths, platinum tones are obtained. —W. C.

XXII.—EXPLOSIVES; MATCHES.

Patents.

Smoke; Production of coloured ——. V. M. L. Experimental, Ltd., and O. D. Lucas. E.P. 185,339, 6.10.21.

A smoke-producing unit comprises a mass of self-combustible composition, stable at normal temperatures, and containing volatilisable colouring matter. The composition is packed in a container having orifices so arranged that on ignition the temperature produced is sufficient to volatilise the colouring matter but not high enough substantially to decompose it. The composition is in the form of pellets which may be ignited by quickmatch and gunpowder. The colouring matter comprises about half the composition, the remainder consisting of sugar or flour as a fuel and potassium chlorate.—H. C. R.

Explosive compositions; Process for increasing the sensitiveness and power of ——. W. M. Dehn. U.S.P. 1,428,011, 5.9.22. Appl., 20.8.20.

Diazodinitrophenol is mixed with other explosive matter under water and the mixture is subsequently dried.—H. C. R.

Priming compositions; Manufacture of —— for percussion and friction fuses, detonators, cartridges and the like. E. R. von Herz. G.P. 289,016, 25.7.13.

Complex compounds of metallic hypophosphites with the metallic salts of inorganic acids yielding oxygen are used. For example, a mixture of 95% of lead nitrate-hypophosphite and 5% of antimony sulphide can be used, or 60% of lead nitrate-hypophosphite, 25% of barium nitrate, and 15% of antimony sulphide, with or without the addition of glass powder. These compounds may be used as substitutes for mercury fulminate.—A. G.

Priming compositions; Manufacture of —— for the percussion caps of small arms, ordnance and projectiles, and similar percussion and friction fuses. E. R. von Herz. G.P. 289,017, 30.7.13.

The normal lead compound of trinitroresorcinol is used as the primer, to which, as damping medium, paraffin, vaseline oil, ceresin, etc. may be added and if necessary other explosives which are not detonators. Primers are thus obtained which are safe against dangers from handling, proof against moisture, and which do not attack metals.—A. G.

Incendiary and explosive compositions. B. Benedix. G.P. 300,020, 16.10.15.

An explosive or incendiary composition consists of a combustible organic substance and a sodium peroxide compound out of direct contact with the organic substance. The fuse consists of an inflammable alcohol of low b.p., particularly methyl alcohol and mixtures containing it, and methyl salicylate is employed as the organic substance.
—A. J. H.

Explosives; Production of gelatinous —— proof against firedamp. Dynamit-A.-G. vorm. A. Nobel u. Co., and P. Naoûm. G.P. 353,200, 15.10.20.

Concentrated sulphite-cellulose waste liquor is added to the explosive in moderate quantity. The plasticity and flexibility of the explosive are increased and in consequence the ease with which it can be incorporated in cartridges, and its stability and ease of detonation are unimpaired.—A. G.

XXIII.—ANALYSIS.

Extraction of liquids by immiscible liquids; Apparatus for ——. Fayolle and C. Lormand. Chim. et Ind., 1922, **8**, 273—274.

Two robust forms of extraction apparatus, for use respectively according as the extracting liquid is heavier or lighter than the liquid to be extracted, and in which the former liquid passes through the latter in a succession of drops, are described. A comparatively small volume, from 50 to 100 c.c., of extracting liquid is required. The apparatus is suitable for the extraction of aqueous solutions of caffeine, digitalin, and morphine by chloroform, extraction of fats from soap solutions by ether etc.
—J. S. G. T.

Turbidity standard. H. Bechhold and F. Hebler. Kolloid-Zeits., 1922, **31**, 132—137.

A turbidity standard, for use in nephelometric work, may be prepared by mixing 1/500 g.-mol. of hydroxylamine sulphate in glycerol with 1/500 g.-mol. of barium chloride also in glycerol. The product contains 1/1000 g.-mol. of barium sulphate consisting of particles 2·5 μ diam. and is stable for eight days. A standard sol is prepared by mixing barium nitrate and magnesium sulphate both dissolved in a mixture of glycerol (85 pts.) and isobutyl alcohol (15 pts.). The sol contains 1/200 g.-mol. of barium sulphate and on mixing with glycerol containing 15% of isobutyl alcohol can be brought to the same turbidity as the first-mentioned standard. It is normally three times as turbid as the standard turbidity and its particles have a diameter not greater than 90 $\mu\mu$. It is stable for at least six months.—J. F. S.

Coagulation of colloids; Apparatus for measuring the rate of ——. Wo. Ostwald and F. V. von Hahn. Kolloid Zeits., 1922, **30**, 62—70.

Two forms of apparatus for determining the rate of coagulation of colloidal suspensions are described. In the one, the colloid is contained in one limb of a U-tube about 130 cm. long and 6 mm. diameter, and is balanced hydrostatically against a liquid, such as distilled water, contained in the other limb, which is about 3·7 mm. in diameter. The rate of coagulation is determined by observing the respective heights of the two liquids in the two limbs. In the second form, the colloid is sucked up into a vertical tube about 2 m. long, connected at the upper end with a closed vessel containing gas and immersed in a bath at constant temperature. The rate of coagulation is determined by observing the rise of level of the top of the column of liquid. The use of the instruments is illustrated in the cases of the coagulation of suspensions of silver sulphide, mercury sulphide, gum mastic, and colloidal gold.
—J. S. G. T.

Sedimentation analysis; Technical ——. F. V. and D. von Hahn. Kolloid-Zeits., 1922, **31**, 96—101.

A slightly enlarged form of the Ostwald and Hahn U-tube coagulation measurer (*cf. supra*) may be used to determine the relative size of the particles of commercial preparations. A description of the use of the instrument to differentiate varieties of lampblack is given.—J. F. S.

Potassium binoxalate and the standardisation of alkali solutions. Y. Osaka and K. Ando. Mem. Coll. Sci. Kyōtō, 1921, **4**, 371—375.

The use of anhydrous potassium binoxalate for the standardisation of alkali solutions is recommended, and a method of preparation of the salt from oxalic acid and potassium oxalate described.—J. S. G. T.

Qualitative chemical analysis. V. Macri. Boll. Chim. Farm., 1922, **61**, 417—418.

The following scheme dispenses with the use of sulphur compounds. The hydrochloric acid solution of the substance to be analysed is placed, together with a stick of zinc, in a flask fitted with a gas-delivery tube, which is heated at one part as with a Marsh apparatus; the flask also is eventually heated. The precipitate thus formed may contain silver, mercury, lead, bismuth, copper, cadmium, platinum, gold, tin, antimony, and arsenic, and is separated by filtration, the filtrate being heated to boiling with zinc acetate. The precipitate thus obtained may contain aluminium, iron, and chromium, and the filtrate from this is heated with hydrogen peroxide, which precipitates manganese. The latter is filtered off and the filtrate heated, and treated with zinc oxide in presence of chlorine, nickel and cobalt being thus precipitated. This subdivision into groups does not hold exactly. Antimony and arsenic may be volatilised, at least partially, as hydrides. Chromium may remain in solution if aluminium and iron are not also present, and in such case may be detected by the yellow coloration obtained when the liquid from the manganese precipitate is rendered alkaline. The last two groups may be combined, since treatment with zinc oxide and chlorine precipitates also the manganese. The separations of the metals in the different groups is not described, but it is pointed out that the first group precipitate is best treated successively with hydrochloric acid, nitric acid, and *aqua regia*; the nitric acid may give a residue of antimonic anhydride, which is readily dissolved by hydrochloric or tartaric acid. The presence of mercury may lead to difficulty as the mercury may be deposited on the zinc and thus prevent its further attack. If oxalates, fluorides, silicofluorides, phosphates, borates, or silicates are present together with alkaline-earth metals, the latter may be precipitated completely or partially as oxalates, fluorides, or silicofluorides; the borates and phosphates remain in solution in an acid medium, whilst the silicates are decomposed. The precipitate should be separated, dried, calcined in presence of a few drops of sulphuric acid, redissolved, and again treated with zinc oxide.—T. H. P.

Barium; Approximate volumetric estimation of ——. M. Polonovski. Bull. Soc. Chim., 1922, **31**, 810—813.

To a measured volume of the solution containing barium an equal volume of 80% alcohol is added, followed by excess of a standardised solution of sodium thiosulphate in 30% alcohol. The separation of barium thiosulphate is facilitated by shaking and is complete in about 24—36 hrs. The temperature and alcoholic content of the solution are then noted, the precipitate filtered off, and the excess of sodium thiosulphate in the filtrate determined, the barium being thus estimated by difference. A correction is necessary on account of the small solubility of barium thiosulphate; the author gives a formula for applying the correction in which temperature and alcoholic content of the solution are factors. The method is applicable in presence of other alkaline-earth metals and may be used for estimation of sulphates; in this case excess of barium is added and the amount remaining in solution is determined.—H. J. E.

Alkaline-earth metals; Method of qualitative separation of ——. M. Polonovski. Bull. Soc. Chim., 1922, **31**, 806—810.

The precipitate of alkaline-earth carbonates is dissolved in a few c.c. of dilute acetic acid, the solution boiled to eliminate all traces of carbon dioxide and neutralised with ammonia. An equal volume of 60% alcohol and the same volume of a saturated solution of sodium thiosulphate in 30% alcohol are added; barium thiosulphate is at once precipitated and the solution should be well shaken and allowed to stand for 10 mins. After filtering, the filtrate is freed from traces of barium by addition of 1/10 of its volume of a solution of potassium sulphate (7 g. per litre). A second filtration removes the barium sulphate, and strontium is detected by adding to the filtrate half its volume of a solution of 1 pt. of sodium sulphite in 300 pts. of 30% alcohol. Complete precipitation of strontium is effected by excess of concentrated solution of sodium sulphite or of potassium sulphate. The filtrate containing calcium is acidified with very dilute acetic acid and the metal precipitated with ammonium oxalate.
—H. J. E.

Arsenite; Effect of iron on the iodine titration of ——. F. L. Melvill. J. S. Afr. Chem. Inst., 1922, **5**, 3—5.

The slightly acid arsenite solution, containing not more than 0·1% of iron, is treated with about one-half the volume of standardised iodine solution required to oxidise all the arsenite, and 10 c.c. of saturated sodium bicarbonate solution is then added. The iron is thus precipitated completely as ferric arsenate and no longer interferes when the titration with the iodine solution is continued to completion.—W. P. S.

Lead nitrate; Electrometric titrations with ——. I. M. Kolthoff, Z. anal. Chem., 1922, **61**, 369—377.

Iodides in solutions of not too low concentration may be titrated with lead nitrate solution, and chlorides and bromides do not interfere if the end-point is determined electrometrically. The method is also suitable for the determination of ferrocyanides, oxalates, tartrates, and succinates, and of sulphates, but in the latter case mineral acids, ferric salts, and aluminium salts must not be present. Electrometric titration of pyrophosphates with lead nitrate solution is, however, untrustworthy.—W. P. S.

Ferrocyanides; Electrometric titration of ——. E. Müller and H. Lauterbach. Z. anal. Chem., 1922, **61**, 398—403.

The end-point of the titration of ferrocyanides in sulphuric acid solution by potassium permanganate solution may be determined electrometrically.
—W. P. S.

Aluminium; Experiments on the oxide method of determining ——. J. E. Clennell. Inst. of Metals, Sept., 1922. [Advance copy.] 16 pages.

Results of experiments show that for the hydrolysis of aluminium salts to hydroxide alkali thiosulphate is more satisfactory than phenylhydrazine or iodide-iodate mixture (*cf.* Ibbotson and Aitchison, "Analysis of Non-Ferrous Alloys," 137, 1915). An acid solution of the aluminium alloy or salt (containing about 100 mg. of aluminium) is made faintly ammoniacal after the usual elimination of silica and metals of the copper group, then diluted to 300 c.c., cooled somewhat, and sulphur dioxide passed through until the precipitate is dissolved and the solution colourless. Dilute ammonia in slight excess is added and 5 g. of sodium thiosulphate (if iron or manganese be present, 10—20 c.c. of 1:3 acetic acid is also added), and the solution is boiled for 30 mins., diluted to 500 c.c. with hot 1% ammonium chloride solution, and, after settling, decanted, similar decantations being repeated twice. The precipitate is then collected in the usual way. Re-treatment of the filtrate by thiosulphate usually yields further small amounts of alumina. For large amounts of iron or zinc, double precipitation is necessary; magnesium does not affect the process. Results are generally high, due to adsorbed salts, undissociated aluminium sulphate, and the hygroscopic nature of the ignited alumina, but with suitable blank assays an accuracy, for small amounts of impurities, within ±0·2% is claimed in the case of alums and of about ±0·5% for alloys. The precipitated hydroxide is flocculent and easily filtered, and the method is applicable to basic corrosion products of aluminium oxidation, *e.g.*, those from the action of water on aluminium amalgam, for which the older methods had proved unsatisfactory.—J. R. P.

Carbon dioxide in air; New apparatus for determination of ——. H. Lundegardh. Biochem. Zeits., 1922, **131**, 109—115.

The author has modified Pettenkofer's method by replacing the flask by an open zinc vessel in the form of a beaker with a detachable cover and fitted with three tubes to facilitate withdrawal and introduction of solutions. A larger apparatus on similar lines, suitable for use in the open, is described and illustrated.—H. K.

Nitrogen; A new accelerator for the destruction of organic matter in the Kjeldahl method for the determination of ——. M. and I. Sborowsky. Ann. Chim. Analyt., 1922, **4**, 266—267.

Mercurous iodide accelerates the destruction of organic matter in the digestion with sulphuric acid much more effectively than metallic mercury or other mercury salts. In two experiments carried out with 10 c.c. of sulphuric acid with mercurous iodide 0·7 g. of sugar was destroyed in the time required for the destruction of only 0·1 g. with metallic mercury. A digestion was completed in 50—60 min., which with metallic mercury took 4—8 hrs.—H. C. R.

Incineration by Kjeldahl's method; Apparatus for —— *on the micro scale.* H. Winkler. Chem.-Zeit., 1922, **46**, 785.

The incineration mixture consists of 300 c.c. of phosphoric acid and 100 c.c. of concentrated sulphuric acid, and to each 100 c.c. of this mixture are added 10 c.c. of a 6% solution of copper sulphate and 10 c.c. of water. 2 c.c. of the mixture is used for an incineration, which is carried out in a Jena glass test-tube of special shape, in the upper part of which is a tube, ending underneath in a funnel and above in a bulb, by which arrangement the ejection of liquid at the moment of reaction is avoided. The test-tube is heated by a strong flame, and the process only requires a few minutes for its completion. The resulting small quantities of ammonia are best distilled in a current of steam. —H. M.

Amino-acid nitrogen; Triketohydrindene (ninhydrin) reaction as a quantitative colorimetric method for estimation of ——. H. Riffart. Bio-Chem. Zeits., 1922, **131**, 78—96.

The ninhydrin reaction is suitable for the quantitative estimation of amino-acid nitrogen if certain precautions are taken. All the amino-acids examined, with free amino-groups, with the exception of histidine, give at p_H 6·976 the same standard colour if the solutions be equal in amino-acid nitrogen content, say 10 mg. or less of amino-acid nitrogen per litre. This result is obtained by taking 2 c.c. of such a solution, neutralising with $N/400$ alkali to p_H 6·976 by comparison with phosphate standards and methyl red, adding 2 c.c. of phosphate solution of the same p_H and 1 c.c. of 1% ninhydrin solution, and heating for half an hour in the water bath. The solutions are then diluted to 100 c.c. and compared colorimetrically. Histidine gives the standard colour at p_H 6·24, thus involving a small error where mixtures of amino-acids containing histidine are estimated. Some amines and ammonium salts also give the colour reaction but only in much higher concentrations than 15 mg. per litre.—H. K.

PATENTS.

Photometric devices. E.P. 184,853, 17.5.21.

Metal; Means for testing the physical properties [elasticity or hardness] of ——. F. S. J. Pile. E.P. 185,253, 18.6.21.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given; they are on sale at 1s. each at the Patent Office, Sale Branch, Quality Court Chancery Lane, London, W.C. 2, 15 days after the date given.

1.—GENERAL; PLANT; MACHINERY.

APPLICATIONS.

Benoit. 26,652. *See* XIX.

Blow, and Renshaw Engineering Works. Extracting and segregating soft penetrable substances from an aggregation of such substances and hard impenetrable substances. 26,117. Sep. 27.

Bowater and Lymn. Preventing formation of scale in boilers, evaporators, etc. 26,867. Oct. 4.

Drey and Hammersley. Refrigeration. 26,623. Oct. 3.

Dried Milk Dairy Products, Ltd., Lampitt, and Palmer. Apparatus for separating and collecting solid particles from air. 26,712. Oct. 3.

Hargraves, Minchin, and Werpe. Means for filtering liquids. 25,899. Sep. 25.

Kemp, and Wellman Seaver Morgan Co. Reversible regenerative furnaces. 27,104. Oct. 6.

Kennedy. Crushing apparatus. 26,533. Oct. 3.

Plausons (Parent Co.), Ltd. (Plauson). Disintegrators. 26,650. Oct. 3.

Rigby. Drying process and apparatus. 26,378. Sep. 30.

Rushen (Fitch). Continuous heating furnaces. 25,974. Sep. 26.

Sharples Specialty Co. Continuously separating substances. 27,184. Oct. 7.

Smidth & Co. Apparatus for separating solid particles from fluids. 26,583. Oct. 2. (Denmark, 3.10.21.)

Stone. Process and apparatus for subliming. 26,881. Oct. 5.

Thornton. 26,052. *See* XIX.

COMPLETE SPECIFICATIONS ACCEPTED.

12,497, 13,303 and 16,186 (1921). Buxton. Drying-apparatus. (186,370.) Oct. 11.

17,520 (1921). Adler. Absorption and purification of gases and vapours. (165,451.) Oct. 11.

18,028 (1921). Adler. Method and apparatus for lixiviation. (166,525.) Oct. 11.

19,299 (1921), 5322 and 10,607 (1922). Spensley. Grinding or disintegrating and mixing machines. (188,462.) Oct. 11.

19,742 (1921). Marks (National Air Dryers, Inc.). Drying apparatus. (186,207.) Oct. 4.

34,874 (1921). Scrive. Drying apparatus. (186,548.) Oct. 11.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Applications.

Ardern and Sheppard. Fuel briquettes. 26,607. Oct. 2.

Barrs. Production of coke from small coal. 26,948. Oct. 5.

Etorre. Preventing fusion etc. of ash from combustion of powdered fuel. 26,330. Sep. 29. (Fr., 29.12.21.)

Fonblanque and Moeller. Drying and use of peat etc. 26,897. Oct. 5.

Grieve, Livens, and Ruston and Hornsby. Gas-producer plants. 26,783. Oct. 4.

Jackson (Koppers Co.). Removal of hydrogen sulphide from gases. 26,715. Oct. 3.

Koppers Co. Removing hydrogen sulphide from gases etc. 26,701—2. Oct. 3. (U.S., 8.12.21.)

Koppers Co. Purifying gases. 26,708 and 26,730. Oct. 3. (U.S., 8.12.21.)

Lewis. Molecular conversion of hydrocarbons and separation of resultant products. 26,114. Sep. 27.

Masson. 27,170. *See* XII.

Pickard. Production of combustible gases. 25,835—7. Sep. 25.

Plausons (Parent Co.), Ltd. (Plauson). Manufacture of lubricants. 26,276. Sep. 29.

Plausons (Parent Co.), Ltd. (Plauson). 26,189. *See* IX.

Powers and Umpleby. Gas generators. 26,016. Sep. 26.

Robinson. Treatment of asphaltic base oils, bituminous products, and tar. 25,870. Sep. 25.

Schauerman. Candles. 26,455. Sep. 30.

Schauerman. Substitute for petrol. 26,456. Sep. 30.

Smallwood. 26,805. *See* XIX.

Soc. Lyonnaise des Eaux et de l'Eclairage. Gasifying and carbonising coal etc. 26,833. Oct. 4. (Fr., 7.10.21.)

Ward. Desulphurisation of oils. 26,861. Oct. 4.

Complete Specifications Accepted.

9129 (1921). Illingworth. Production of smokeless fuels and coke. (186,085.) Oct. 4.

14,472 (1921). Marshall. Retorts for treating carbonaceous and other materials. (186,375.) Oct. 11.

14,676 (1921). Illingworth. Coking of coal. (186,384.) Oct. 11.

16,874 (1921). Testrup, and Techno Chemical Laboratories, Ltd. Utilising surplus power from hydro-electric plant for preparing peat or similar fuel. (186,137.) Oct. 4.

16,913. (1921). Price, and Minerals Separation, Ltd. Treatment of coal. (186,143.) Oct. 4.

27,625 (1921). Climie. Gas producers. (186,202.) Oct. 4.

III.—TAR AND TAR PRODUCTS.

Applications.

Dodd, Sprent, and United Alkali Co. Manufacture of *p*-dichlorobenzene and chloroanthraquinone. 26,343. Sep. 29.

Masters. Manufacture of *β*-naphthol 2.3.6- and 2.6.8-disulphonic acids. 26,021. Sep. 27.

Masters. Separation of isomeric naphthylamine sulpho acids. 26,022. Sep. 27.

Masters. Manufacture of *α*- and *β*-naphthols. 26,023. Sep. 27.

Robinson. 25,870. *See* II.

Complete Specification Accepted.

24,139 (1921). British Dyestuffs Corp., Baddiley, Payman, and Bainbridge. Manufacture of 1.4-naphtholsulphonic acid. (186,515.) Oct. 11.

IV.—COLOURING MATTERS AND DYES.

Applications.

Bloxam (Akt.-Ges. f. Anilinfabr.). Manufacture of tetrakisazo dyestuffs. 26,116. Sep. 27.

British Dyestuffs Corp., Green, and Saunders. Manufacture of azo dyestuffs. 25,989. Sep. 26.

Complete Specifications Accepted.

18,732 (1921). Durand et Huguenin Soc. Anon. Manufacture of mordant dyeing colouring matters. (166,530.) Oct. 4.

21,454 (1921). Soc. Chim. de la Grande Paroisse. Brown dyestuffs. (169,687.) Oct. 4.

24,456 (1921). British Dyestuffs Corp., Baddiley, Rodd, and Stocks. Manufacture of basic dyestuffs possessing affinity for unmordanted vegetable fibres. (186,517.) Oct. 11.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Applications.

Dreyfus. Manufacture of products from cellulose derivatives. 27,083. Oct. 6.

Ironside. Treatment of jute. 27,163. Oct. 7.

Marshall. Manufacture of fabrics containing artificial silk. 26,880. Oct. 5.

Milne. Manufacture of paper. 27,017. Oct. 6.

Ros. Treatment of fibrous materials. 26,953. Oct. 5.

Complete Specifications Accepted.

8492 (1921). Acree. Converting wood into sugar and other products. (160,776.) Oct. 4.

8493 (1921). Acree. Converting wood into mucic acid and other products. (160,777.) Oct. 4.

13,850 (1921). Eyrich and Schreiber. Removal of ink from print-paper. (186,372.) Oct. 11.

16,886 (1921). Terrisse and Levy. Obtaining glucose and dextrin from wood. (186,139.) Oct. 4.

16,975 (1921). Steinhilber. Production of cellulose from reeds and similar plants. (179,885.) Oct. 4.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Applications.

Beck. Colouring cotton. 26,158. Sept. 28.

Schauerman. Composition for fireproofing and waterproofing materials. 26,457. Sept. 30.

Complete Specifications Accepted.

9192 (1921). Aris. Fixing colours on textile fibres. (186,086.) Oct. 4.

3272 (1922). Imray (Gebr. Schmid). Dyeing silk black. (174,947.) Oct. 11.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Applications.

Coke and Gas Ovens, Ltd., and Smith. Production of white commercial pure ammonium chloride. 26,967. Oct. 5.

Dreyfus. Production of products from alkali compounds. 26,959. Oct. 5.

Hovey and Hovey. Nitrate of lime. 26,883. Oct. 5.

Howard. Production of hydrogen sulphide. 26,739. Oct. 3. (U.S., 20.10.21.)

Jackson (Koppers Co.). 26,715. *See* II.

Jackson (Koppers Co.). Manufacture of hydrogen sulphide. 26,722. Oct. 3.

Koppers Co. 26,701—2. *See* II.

Koppers Co. Manufacture of hydrogen sulphide. 26,721. Oct. 3. (U.S., 8.12.21.)

Nitrogen Corp. Synthesising ammonia. 26,000. Sep. 26. (U.S., 5.10.21.)

Rawson. Treatment of hydromagnesite. 25,983. Sep. 26.

COMPLETE SPECIFICATION ACCEPTED.

19,113 (1921). Plausons (Parent Co.), Ltd. (Plauson). Extraction of alkali from felspar and other minerals. (186,199.) Oct. 4.

VIII.—GLASS; CERAMICS.

COMPLETE SPECIFICATION ACCEPTED.

17,049 and 30,326 (1921). Hilger, Ltd., and Twyman. Annealing and apparatus used therein. (186,160.) Oct. 4.

IX.—BUILDING MATERIALS.

APPLICATIONS.

Avis and Jennings. Material for structural purposes. 25,877. Sep. 25.

Dunstan. Cementitious composition. 26,869. Oct. 4.

Plausons (Parent Co.), Ltd. (Plauson). Production of cement from oil shale and simultaneous recovery of shale oil. 26,189. Sep. 28.

COMPLETE SPECIFICATIONS ACCEPTED.

35,073 (1920). Hamon. Compositions for making building blocks, slabs, tiles, etc. (186,355.) Oct. 11.

14,234 (1921). Rowse. Manufacture of roofing and building material. (186,105.) Oct. 4.

17,026 (1921). Imperial Trust, and Schryver. Manufacture of plastic material for flooring etc. (186,157.) Oct. 4.

20,006 and 20,198 (1921). Soc. de Recherches et de Perfect. Industriels. Impregnation of wood. (168,048 and 179,129.) Oct. 4.

21,843 (1921). Arquint. Insulating material against loss or gain of heat. (186,492.) Oct. 11.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

APPLICATIONS.

Brewer (Krupp A.-G.). Electrolytic separation of pure chromium in thick layers. 26,206. Sep. 28.

Campbell. Reduction of metallic oxides and ores in melting furnaces. 26,470. Sep. 30.

Classen. Production of glossy metallic coatings on metals. 26,014. Sep. 26.

Fréson. Siemens etc. furnaces. 26,962. Oct. 5. (Belg., 11.10.21.)

Green and Hatfield. Alloy steels. 26,296—9. Sep. 29.

Jones. Distillation of zinc etc. by electrical means. 27,006. Oct. 6.

Meehan. Manufacture of grey iron. 25,973. Sep. 26.

Miles. Froth flotation machines etc. 27,086. Oct. 6.

Smallwood. Process for making ore or fuel briquettes. 26,805. Oct. 4.

Smidth & Co. Agglomeration of ore. 27,191. Oct. 7. (Sweden, 11.10.21.)

Ward. Melting metals. 27,156. Oct. 7.

COMPLETE SPECIFICATIONS ACCEPTED.

14,603 (1921). Jones, and Sylvette, Ltd. Nickel alloys. (186,381.) Oct. 11.

16,456 (1921). Thompson (Thoumyre Fils). Lead alloys. (186,118.) Oct. 4.

17,049 and 30,326 (1921). Hilger and Twyman. *See* VIII.

19,074–5 (1921). Fierz and Prager. Manufacture of nickel from nickel carbonyl. (186,457—8.) Oct. 11.

19,090 (1921). Classen. Production of glossy metallic coatings on metals. (186,459.) Oct. 11.

22,381 (1921). General Electric Co., and Smithells. Manufacture of tungsten. (186,497.) Oct. 11.

24,843 (1921). Boehm. Manufacture of magnesium foil. (186,253.) Oct. 4.

25,480 (1921). Hibbard. Art of puddling. (179,888.) Oct. 4.

XI.—ELECTRO-CHEMISTRY.

APPLICATIONS.

Brewer (Krupp A.-G.). 26,206. *See* X.

Dutt. Electric primary batteries. 26,927. Oct. 5.

Dutt and Godfrey. Storage batteries. 26,928. Oct. 5.

Dutt and Godfrey. Electric batteries. 26,929. Oct. 5.

Dutt and Godfrey. Leclanché batteries. 27,106. Oct. 6.

Fischer and Pörscke. Galvanic cells and batteries. 26,843—4. Oct. 4.

Hancock and Hancock. Electric furnaces. 27,068. Oct. 6.

Jones. 27,006. *See* X.

McMullen and Rickets. Electrical systems and apparatus for chemical treatment of non-conducting liquids. 26,692. Oct. 3.

Metropolitan-Vickers Electrical Co., and North. Insulating materials. 26,838. Oct. 4.

Reynolds. Composition for screening X-ray emanations and for electrical insulation. 26,254. Sep. 28.

Stobie. Electric arc furnaces. 26,905. Oct. 5.

XII.—FATS; OILS; WAXES.

APPLICATIONS.

Ashwell. 26,621. *See* XIII.

Bannister. 26,319. *See* XIII.

Masson. Purification of oils. 27,170. Oct 7.

COMPLETE SPECIFICATIONS ACCEPTED.

8040 and 25,857 (1921). Macpherson and Heys. *See* XIX.

16,749 (1921). MacIlwaine. Preservation and preparation for transportation of oil-bearing raw material, such as nuts, seeds, and copra. (186,133.) Oct. 4.

17,239 (1921). Goslings. Purification of oils and fats. (172,923.) Oct. 11.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

APPLICATIONS.

Ashwell. Apparatus for drawing off, condensing, and collecting vapours and fumes from gums, oils, etc. 26,621. Oct. 3.

Bain, and Barry, Ostlere, and Shepherd. Manufacture of linoleum etc. 26,493. Oct. 2.

Bannister and Bannister. Manufacture of French-polishing oil. 26,319. Sep. 29.

Calwell. Writing inks. 25,826. Sep. 25.

New Jersey Zinc Co. Manufacture of lithopone. 25,909. Sep. 25. (U.S., 2.11.21.)

Peters. Paint or coating composition. 26,608. Oct. 2.

Plausons (Parent Co.), Ltd. (Plauson). Paints. 25,813. Sep. 25.

Complete Specifications Accepted.

15,942 (1921). Imray (Soc. Chem. Industry in Basle). Manufacture of resins. (186,107.) Oct. 4.

16,404 (1921). White (National Lead Co.). Manufacture of white lead. (186,114.) Oct. 4.

17,025 (1921). Imperial Trust, and Schryver. Manufacture of coating compositions. (186,156.) Oct. 4.

17,151 (1921). Pummerer. Production of artificial resins. (165,408.) Oct. 4.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Applications.

Bourne and Whitehead. Rubber compositions. 26,443. Sep. 30.

Clarke, Roberts, and Skellon. Vulcanisation of rubber. 27,114. Oct. 6.

Rushen (Naugatuck Chemical Co.). Vulcanisation of rubber. 25,972. Sep. 26.

Schauerman. Substitute for rubber, vulcanite, etc. 26,458. Sep. 30.

XV.—LEATHER; BONE; HORN; GLUE.

Applications.

Aström. Manufacture of waterproof leather. 26,099. Sep. 27.

Comp. Gén. d'Electricité. Moulding casein into plates having polished surface. 25,908. Sep. 25. (Ger., 26.9.21.)

Hoare. 26,340. *See* XIX.

XVI.—SOILS; FERTILISERS.

Complete Specifications Accepted.

21,170 (1921). James (Eisenwerkges. Maximilianshütte). Treatment of phosphorus compounds suitable for manurial purposes. (186,223.) Oct. 4.

22,272 (1921). Stockholms Superfosfat Fabriks Aktiebolag. Granulation of calcium cyanamide. (168,070.) Oct. 11.

XVII.—SUGARS; STARCHES; GUMS.

Application.

Harding and Whetham. Manufacture of lactose and/or lactalbumen. 26,879. Oct. 5.

Complete Specifications Accepted.

8492 (1921). Acree. *See* V.

16,886 (1921). Terrisse and Levy. *See* V.

XVIII.—FERMENTATION INDUSTRIES.

Application.

Sobotka and Willstätter. Production of yeast preparations for food. 25,895. Sep. 25.

Complete Specification Accepted.

17,077 (1921). Hyde. Brewing malt liquors. (186,161.) Oct. 4.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

Applications.

Adams. Sewage purification tanks etc. 27,015. Oct. 6.

Benoit. Purification of liquids. 26,652. Oct. 3.

Comp. Indus. de Travaux d'Edilite. Furnace for incinerating refuse. 25,891. Sep. 25. (Fr., 24.8.22.)

Dried Milk Dairy Products, Ltd., and others. 26,712. *See* I.

Hampshire, Hobbs, and Co., and Jones. Drying fish and vegetable substances etc. 26,644. Oct. 3.

Harding and Whetham. 26,879. *See* XVII.

Harrington. Deodorisers or disinfectants. 26,801. Oct. 4.

Hoare. Manufacture of vegetable casein or albumin. 26,340. Sep. 29.

Linley. Treatment and storage of meat. 26,589. Oct. 2.

Seligman. Sterilising and preserving liquids. 26,974—6. Oct. 5.

Sobotka and Willstätter. 25,895. *See* XVIII.

Thornton. Composition for preventing rust etc. in containers for water and for keeping water fluid below freezing point. 26,052. Sep. 27.

Ward Baking Co. Manufacture of bread. 26,616, 26,749, and 26,750. Oct. 2 and 3. (US., 1. and 3.10.21.)

Ward Baking Co. Production of food products. 26,617. Oct. 2. (U.S., 1.10.21.)

Ward Baking Co. Production of enzymes for manufacture of bread. 26,751. Oct. 3. (U.S., 3.10.21.)

Ward Baking Co. Coagulating and curdling milk. 26,752. Oct. 3. (U.S., 3.10.21.)

Complete Specification Accepted.

8040 (1921). Macpherson and Heys. Antiseptic and insecticidal soap or compound. (186,078.) Oct. 4.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Applications.

Engelhardt, and Farbenfabr. vorm. F. Bayer u. Co. Separating or isolating organic gases or vapours of organic products. 26,841. Oct. 4.

Holzverkohlungs-Industrie A.-G. Chlorination of methane. 27,107. Oct. 6. (Ger., 27.3.22.)

Lewis. 26,114. *See* II.

Complete Specifications Accepted.

8493 (1921). Acree. *See* V.

17,527 (1921). Elektrizitätswerk Lonza. Production of crotonic acid from crotonaldehyde. (165,728.) Oct. 4.

19,376 (1921). Johnson (Badische Anilin u. Soda Fabrik). Manufacture of thymol. (186,202.) Oct. 4.

31,276 (1921). Holzverkohlungs-Industrie A.-G., and Roka. Chlorination of methane. (186,270.) Oct. 4.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Application.

Marks (Daylight Film Corp.). Photographic developers. 27,200. Oct. 7.

Complete Specification Accepted.

11,556 (1921). Wolff. Negative material for colour photography. (168,035.) Oct. 11.

XXII.—EXPLOSIVES; MATCHES.

Applications.

De Wendel et Cie. Explosive. 26,989. Oct. 5. (Fr., 21.1.22.)

Friederich. Process for making charges for fuse cords etc. 26,577. Oct. 2.

XXIII.—ANALYSIS.

Application.

Bellingham and Stanley. Polarimeters etc. 26,725. Oct. 3.

I.—GENERAL; PLANT; MACHINERY.

Patents.

Boilers and the like; Compositions for preventing corrosion and removing incrustation in ——. The Zynkara Co., Ltd., and W. A. Cross. E.P. 185,035, 7.10.21.

Alkaline solid material of the kind usual in boiler compositions, *e.g.*, powdered caustic soda, is mixed with finely-divided zinc or other metal electro-positive to the metal of the boiler; the mixture is incorporated with a melted wax or other material of comparatively low melting-point not attacked by alkalis, and allowed to solidify.—H. H.

Electrolytic corrosion in surface condensers and like heat exchange apparatus; Prevention of ——. F. von Wurstemberger. E.P. 185,436, 8.3.21.

When iron parts (such as longitudinal stays) are used in conjunction with copper or copper alloys in condensers, precautions are taken to prevent contact of the iron parts with the copper (or alloy) tube-plates, the iron parts being provided with copper ends. In the case of intermediate copper tube-supporting plates, holes with a large clearance, and preferably bevelled to prevent water settling in them, may be used where the stays pass through. —B. M. V.

Pulverising, mixing, and grading; Apparatus for ——. W. Clark, G. and W. A. Dawson. E.P. 185,037, 10.10.21.

In an apparatus for pulverising wet or dry materials, with or without mixing, and for grading, assisted by induction of hot or cold fluids, a rotor or a travelling member co-acts with a casing. Wire or wire carding is used to form the grinding surfaces or parts thereof on the casing and on the rotor or travelling member. Other grinding parts may be formed as blades on the rotor etc. or as rotor arms, or as adjustable segmental blocks on the inner face of the casing. The grinding parts are arranged to be not actually in contact. Air or other fluids are inducted or injected through inlets provided in the casing and in some cases also in the revolving members. A grading attachment may be provided in which an intermittent blast co-operates with a duct, the cross-section of which increases abruptly.—H. H.

Tube mill. J. Ferencz. U.S.P. 1,428,687, 12.9.22. Appl., 30.4.21.

Hollow trunnions at the ends of a drum are supported in journal bearings on a pair of pedestals. From a standard secured to one pedestal an arm extends through the adjacent trunnion and carries a bar disposed longitudinally within the drum. Grinding rollers suspended from the bar co-operate with the inner surface of the drum to grind material fed into the drum.—H. H.

Baking or drying substances at high temperatures; Apparatus for —— *and subsequently cooling same.* B. Greenwood, and Carr and Co., Ltd. E.P. 185,460, 3.5.21.

The goods (*e.g.*, biscuits) are caused to ascend through a tower divided into a number of sections, each of which can be independently heated, preferably by means of hot air. On arrival at the top of the tower the goods pass through an air lock and descend another tower in which they meet a current of cool air, which leaves the tower at a point below the air lock for transfer of the goods. The speed of descent may be slower than the speed of ascent. —B. M. V.

Pulveriser; Rotary ——. W. H. Fulcher. U.S.P. 1,429,333, 19.9.22. Appl., 14.11.21.

A conical shell rotates about a fixed conical body, the material being crushed in the space between the two. As the shell rotates it is lifted and allowed to drop by means of cams, fixed to the shell, which engage with rollers running on a circular track below the shell, the rollers being mounted on a spider to keep them a fixed distance apart from each other.—B. M. V.

Heater and heat insulation. W. S. Hadaway, jun. U.S.P. 1,389,192, 30.8.21. Appl., 26.7.17.

A heated vessel or chamber is insulated by means of a porous body through which a fluid is caused to flow in opposition to the flow which the heat losses tend to produce. For example, a furnace chamber may be made with walls composed of a large number of capillary tubes, the ends of the tubes on the bottom extending downwards into water contained in a tank enclosed by an outer insulating wall. The spaces above the water and surrounding the tubes of the side walls of the furnace chamber are filled with asbestos wool or like material constituting a wick. The flow of heat outwards from the furnace chamber is counteracted by water flowing inwards through the wick and tubes, the water being gradually converted into steam, with absorption of heat. Various other forms of apparatus based on the same principle are described.

Tunnel-kiln air-heater. L. Wilputte, Assr. to American Dressler Tunnel Kilns, Inc. U.S.P. 1,389,408, 30.8.21. Appl., 20.11.19.

A tunnel kiln for delivering large volumes of hot air for drying or the like comprises a housing of refractory material provided with a number of parallel combustion chambers, similar to those of Dressler tunnel kilns, and with spaced pipes extending longitudinally and forming extensions of the combustion chambers. A mixture of preheated air and fuel is burnt in the combustion chambers and the air to be heated flows in a tortuous path between and in contact with the pipes and in a general direction opposite to the flow of products of combustion through the combustion chambers and pipes.

Drying apparatus; Process of heating —— *by means of furnace gases.* C. Loeser. G.P. 355,845, 8.12.16.

Hot furnace gases are delivered to a tube, disposed within the drying chamber and surrounded by a jacket through which a regulated supply of air flows, the hot gases imparting heat to the air, which then passes through orifices in the furnace gas tube into a mixing header. The mixture is then immediately used for drying purposes. The plant can be operated with just the amount of air required for the combustion of the combustible constituents of the furnace gases, and the material to be dried treated at the highest permissible temperature. —J. S. G. T.

Condensation of steam or other vapours. [Evaporative condenser.] D. McN. Ramsey. E.P. 185,462, 3.5.21.

The evaporating surface of an evaporative condenser with a rotating cage of tubes is smooth and clean and is dipped periodically into a liquid of which the surface tension is less than that of water (*e.g.*, dilute caustic soda solution). The liquid is also maintained cooler at the steam outlet end than at the inlet, for example, by hindering circulation in the dipping trough by one or more intermediate baffles and by sloping the tube towards the outlet, so that drops of liquid cooled by evaporation fall back into the cold end. Steam may be cut off from the tubes that are actually being dipped in the cooling liquid.—B. M. V.

Refrigeration; Process and machine for ——. W. Stewart. E.P. 185,607, 11.8.21.

A liquid (*e.g.*, water) to be solidified by refrigeration is sprayed upwards into a container (or set of containers) the walls of which are cooled and in which a vacuum may be maintained, ice being built up on the walls until a sufficiently thick block is formed; any uncongealed liquid falls into the source of supply and the vapour is removed by an exhauster and condensed and the condensed product used for cooling the external refrigerant. The rate of refrigeration is adjusted so that solid ice and not snow is formed, and when the blocks are thick enough heat instead of cold may be applied to the outside of the container and the blocks allowed to drop upon a rising and falling platform. The latter may be constituted by the supply tank or tanks, and air-tight joints are formed by means of inflatable tubular rubber rings between it and the bottoms of the ice containers. The apparatus is suitable also for the recovery of paraffin wax from oils.—B. M. V.

Emulsions; Method and apparatus for making ——. G. B. Hutchings. E.P. 185,618, 22.8.21.

The apparatus consists of a hollow truncated cone with ducts in the walls. The ducts extend from the base to the top and are also connected with the interior of the cone. When the cone is rotated at high speed in the material to be emulsified, liquid is drawn up into the interior of the cone and passes out by the ducts, an emulsion being formed. The vortex formed in the liquid causes the top of the cone to be always uncovered and by this means a certain amount of air is drawn in. If this is undesirable, the operation is carried out in a vacuum. —T. A. S.

Filters or strainers and sifting surfaces. G. C. Hurrell. E.P. 185,638, 13.9.21. Addn. to 174,116 (*cf.* U.S.P. 1,414,132; J., 1922, 449 A).

The wire for the filtering or straining surface described in the earlier patent (convolutions of wire wound on a squirrel cage) is of cruciform, oblong, oval, or other non-circular cross-section, and is twisted. A similar effect may be produced by cutting a spiral on the wire or by winding a finer wire in an open spiral on the main wire. Either form of the special wire may be used alone or alternating with plain wire.—B. M. V.

Filter-presses; Process for removing solid residues from ——. H. Jung. G.P. 355,483, 2.4.19. Addn. to 339,005 (J., 1921, 800 A).

Solid press-cake contained in the apparatus described in the chief patent is loosened by contact with a stationary bar, and blown by air out of the chambers.—L. A. C.

Vacuum [evaporating] apparatus. T. and J. R. Ray, Assrs. to Ray Bros. Corp. U.S.P. 1,428,557, 12.9.22. Appl., 3.12.17.

The heating drum of a vacuum evaporator is provided with end plates each formed with a series of openings. The peripheral outer edge of each opening is inclined, and tubes connecting the plates terminate within the openings below the inclined portions. The outer ends of the tubes are bevelled to fit these inclined portions.—H. H.

Liquids; Process for evaporating ——. A.-G. Kummler und Matter. G.P. 355,602, 14.4.20. Addn. to 347,070 (*cf.* E.P. 123,716; J., 1920, 287 A).

In the process described in the chief patent, the vapour introduced directly into the apparatus is only compressed to such a degree that it is able to overcome the pressure prevailing at the exit. —L. A. C.

Cleaning air and other gases; Apparatus for ——. H. N. Edens. U.S.P. 1,428,950, 12.9.22. Appl., 20.10.19.

A closed casing contains a liquid reservoir, and the space above the liquid is connected with a device for creating a vacuum. The gas is drawn through a passageway provided with a return bend below the liquid level, and a liquid inlet port is disposed in the outer wall of the bend. The discharge end of the passageway is disposed above the liquid level. —H. H.

Lye solution; Means for regulating and controlling the strength of ——. S. J. Dunkley, Assr. to Dunkley Co. U.S.P. 1,429,129, 12.9.22. Appl., 8.8.21.

The apparatus consists of a main tank connected by delivery and return pipes with a mixing tank. The delivery pipe is provided with a regulating valve, controlled electrically by a hydrometer which responds to changes in density of the liquid in the main tank.—D. J. N.

Contact material; Process for cleaning ——. T. L. Briggs, Assr. to General Chemical Co. U.S.P. 1,429,222, 19.9.22. Appl., 15.9.20.

A catalyst mounted on fibrous material is washed with water without disarranging it.—B. M. V.

Gaseous mixtures; Separation of —— [*by liquefaction*]. P. E. Haynes, Assr. to The Linde Air Products Co. U.S.P. 1,429,242, 19.9.22. Appl., 12.4.19.

In a process in which a compressed gas mixture is expanded with partial liquefaction, the mixture, before expansion, is cooled by heat interchange with the liquefied portion and with gases which have passed through the expansion stage.—B. M. V.

Adsorption apparatus for solvent recovery etc. R. R. Etter, Assr. to General Electric Co. U.S.P. 1,429,856, 19.9.22. Appl., 7.1.21.

An annular chamber with both concentric walls perforated is filled with solid adsorbent material, and the vapour-laden gases together with a heating medium are passed through radially in either direction.—B. M. V.

Washing salts; Apparatus for ——. F. Hornung. G.P. 357,594, 22.8.20.

An inclined drum is divided by partitions into compartments to which salt and washing fluid are delivered, and in which an agitator, comprising mixing and conveying vanes, is arranged. The latter are so shaped that the whole of the salt is not withdrawn from the first compartment, a little remaining behind and serving as a filter for the finer particles of salt. Washed salt is delivered to a bucket conveyor, provided with a partition, so that the washing fluid can be supplied to the washing plant in counter current to the solution of salt delivered from the apparatus. A heating device arranged below the drum enables the apparatus to be employed also for dissolving the crude salt. —J. S. G. T.

Filter. A. M. Capro. U.S.P. 1,429,488, 19.9.22. Appl., 19.6.20.

See E.P. 172,491 of 1920; J., 1922, 116 A.

Filtering apparatus. E. W. W. Keene. U.S.P. 1,429,913, 19.9.22. Appl., 20.4.22.

See E.P. 179,494 of 1921; J., 1922, 490 A.

Fluids; Apparatus for measuring, mixing or separating ——. H. Liese. E.P. 163,015, 6.5.21. Conv., 6.5.20.

Separating or sorting fragmentary materials by electric conductivity; Apparatus for ——. H. L. A. Schweitzer. E.P. 165,098, 20.6.21. Conv., 18.6.20.

Furnaces; Sealing device for travelling grate ——. Zellstoff-fabrik Waldhof, and A. Schneider. E.P. 185,974, 8.10.21.

Ore crusher. B. A. Mitchell. E.P. 186,162, 22.6.21.

Separating constituents of gaseous mixtures. E.P. 184,454. *See* VII.

Separating mixed gases. G.P. 347,601 and 354,630. *See* VII.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Coals; Origin of ——. E. Donath and A. Lissner. Brennstoff-Chem., 1922, 3, 231—237.

The current chemical and geological theories of coal formation are critically reviewed. The theory of the transformation of wood and peat through lignites to coal and anthracite is being modified. Coal is not to be regarded as necessarily derived from peat as found in recent deposits and from brown coals such as exist now. That the brown coals and coal result from different kinds of vegetable matter is a view supported by the authors. They accept the Fischer-Schrader theory of the formation of coal from lignin (J., 1921, 172 a; 1922, 207a, 317 a), the cellulose being destroyed by bacterial action, but the theory is regarded as incomplete in ignoring the vegetable and animal proteins. The proportion of nitrogen in coal is such as to imply the existence of considerable quantities of these. There is some evidence of the possibility of union of protein with cellulosic matter, which would then be preserved. The true coals and harder lignites have probably passed through a pressure distillation process as imitated by Bergius (*cf.* J., 1913, 462).—H. J. H.

Peat; Artificial drying of ——. G. Keppeler. Brennstoff-Chem., 1922, 3, 237—239, 249—254, 262—269.

Evaporation of the water from peat by artificial heat is impracticable, because the fuel requirement exceeds the calorific value of the product. It is conceivable that the evaporation might be effected in closed vessels with the production of steam from which an equivalent of power might be obtained, but this has not proved feasible in practice. The expression of the water is extremely difficult owing to the colloidal character of the peat, and the difficulty seems to increase as the peat ages owing to the breaking down of the cell structure which provided channels of egress for the water. The author and Raapke have shown that, given time, which is the dominating factor, most of the water can be removed from the newer raw peat by pressure, but with an older specimen not even by prolonged application of the highest pressure could the water content be reduced below 75%. It is improbable that mechanical expression or centrifuging of raw peat will prove effective. The removal of water is facilitated by admixture of dry, powdery materials. The further dewatering is rendered much easier by admixture of peat dried to 10—20% of water. By this means the bulk of the water can be removed from the peat by machines described in the paper. This "wet pressing" is regarded as the most promising process. Unsuccessful attempts have been made to facilitate the removal of water by addition of electrolytes or liquids which have a greater wetting power than water. Freezing is effective if moss litter is required but the product is insufficiently coherent for fuel purposes. Similarly the preliminary application of heat facilitates subsequent removal of water as in the "wet carbonising" process, though this has not established itself in practice. Electro-osmose is effective, but owing to the small output per unit, has not proved commercially feasible. After surveying the whole field of artificial methods the author concludes that there is no immediate prospect that any will be successful and he concludes that the most promising field is the development of mechanical appliances to facilitate the winning of peat to be dried in the normal way.
—H. J. H.

Distillation gases of solid fuels; Composition of ——. M. Dolch and G. Gerstendörfer. Brennstoff-Chem., 1922, 3, 225—231.

An attempt is made to correlate the composition of the gas obtained in carbonisation with the geological character and age of the coal taken. The authors have made a large number of carbonisation tests on coals from Ostrau (German Austria). The results are shown graphically. The oxides of carbon, hydrogen, heavy hydrocarbons and tar yields fall off as the geological age increases, whilst the methane yield increases. The hydrogen content of the gas varies inversely with methane content, the sum of the two being practically constant. It is inferred that the former is a secondary product.
—H. J. H.

Carbon monoxide; Catalytic reduction of ——. G. Fester. Brennstoff-Chem., 1922, 3, 244—245.

An observation by Orlow has been confirmed (*cf.* J., 1909, 301), viz., that carbon monoxide when reduced at 100° C. by hydrogen in presence of a catalyst of nickel and palladium asbestos yields unsaturated hydrocarbons and not methane. The catalyst rapidly loses its activity.—H. J. H.

Petrols for road vehicles and aircraft. Effect of fuel composition upon engine performance. O. Thornycroft. J. Inst. Petrol. Tech., 1922, 8, 376—396.

In internal combustion engines operating on the constant-volume cycle, when the air: fuel ratio is that giving complete combustion, with a 5:1 compression, the maximum temperature is about 2600° C., instead of 3000° C. as calculated, on account of dissociation and the increase in the specific heat of the gases at high temperatures. This loss may be reduced by working with a weaker mixture of fuel to air. An infinitely weak mixture would give theoretical efficiency. The mixture strength cannot be reduced below 80% of normal because of difficulties in attaining combustion. Maximum efficiency is attained with 85% of normal, with benzene vapour as fuel. The ratio between experimental efficiency and the air cycle efficiency is increased with increased compression ratio, because the extent of dissociation is lessened. The efficiency of the cycle is practically independent of the variation in carbon and hydrogen contents of hydrocarbons, for while for carbon dioxide the dissociation is great at high temperatures, the increase in specific heat is small, and for water the dissociation is small but the increase in specific heat great. These effects balance each other. There is steady increase in efficiency with increased compression. The rate of increase of efficiency with increased compression is actually greater than that of the air cycle efficiency. All hydrocarbon fuels give the same efficiency at the same compression. Power output increases with compression ratio, but less rapidly than fuel efficiency and slightly less rapidly than the air cycle efficiency. All hydrocarbons give practically the same mean effective pressure or maximum power at the same compression. Detonation and pre-ignition, however, prevent the increase of the compression ratio. The detonation point of heptane corresponds to a compression of 3·75:1, and that of benzol to a compression of 7·1:1. The facility of starting with a given petrol is a function of the volatility of the first 10 to 20% of distillate. To avoid troubles in lubrication the final boiling point of the petrol should not be above 220° C.—H. M.

Ozonides from petroleum. R. Koetschau. Z. angew. Chem., 1922, 35, 509—513.

EXPERIMENTS were made on the action of ozone on American petroleum oils. A transformer oil of sp. gr. 0·915 and molecular weight (by the freezing point method in benzene) 293, yielded 25% of an ozonide having a molecular weight of 663. When a solution of the ozonide in benzene was left for a few hours the molecular weight fell to 606, and after two days, to 479. The value 663 corresponds closely to the calculated molecular weight of a dimeric diozonide, $(C_{19}H_{20}O_6)_2$, viz., 688. Many American crude oils and lubricating oils contain hydrocarbons very rich in carbon, possessing high sp. gr. and high refractive indices, probably saturated polycyclic paraffins. The molecular weights of mineral oils determined by the freezing point method in camphor are generally lower than those determined in benzene. The ozonides from Texas and Pennsylvanian spindle oils have a characteristic pungent odour. When these oils are ozonised the ozonides separate as a flocculent whitish precipitate, which gradually changes to a red resin at a temperature of 20° C. or over. Oils poor in sulphur give more stable ozonides of a lighter colour. The curves of ozone absorption are very steep at their commencement. The maximum increase in weight by absorption of ozone is 16—17%. The "white oils" show no separation of ozonides, but a considerable increase in viscosity when ozonised. On ozonising a Russian petroleum jelly a strong odour of vanilla was developed. Tables are given showing the properties of several ozonised oils and the distillation tests *in vacuo*, and graphs show the relation of quantity of ozone absorbed to time of reaction. A "splitting number" determined by measuring the acidity of an ozonised oil after boiling for half-an-hour with water, has been found of utility for the examination of transformer oils. Sludge values may be determined more rapidly and conveniently with ozone than with oxygen. The value is four to five times greater than with the old method. A table is given showing the amount of ozone absorbed, the sludge value, and the "splitting number" for a transformer oil for periods of reaction from 40 mins. to 5 hrs. A standard method of determination of sludge value is proposed, and details of the cost of ozone production are given.—H. M.

Acetylene and nitrogen. Garner and Matsuno. *See* VII.

Ichthyol. Pépin and Reaubourg. *See* XX.

PATENTS.

Fuel for briquetting purposes; Method of treating ——. G. Komarek, Assr. to Malcolmson Engineering and Machine Corp. U.S.P. 1,430,386, 26.9.22. Appl., 31.12.20.

COAL dust is mixed with a binder, heated in a vertical column, and kneaded in the lower part of the column.—H. Hg.

Peat; Process and apparatus for dewatering ——. Nederlandsche Veenverwerking Maatschappij. G.P. 356,823, 20.1.21. Conv., 10.1.21.

PEAT is passed continually downwards through a vertical shaft furnace so that the hot gases and vapours evolved in the lower zone, where the combined water is liberated, pass upwards through the still wet peat and assist in drying it in the upper zone of the furnace, thus economising fuel.
—A. R. P.

Pulverulent fuels; Method of and means for burning ——. R. S. Walker, Assee. of E. B. Worthington. E.P. 166,124, 24.6.21. Conv., 9.7.20.

A STREAM of pulverised fuel with a partial supply of air is directed downwards at a low velocity into a combustion chamber. Additional air is admitted to the lower part of the chamber, and the flame reverts in an upward direction over an inclined surface on which fused ash is deposited. If slag accumulates on the lower part of the surface, the flame is temporarily deflected in a downward direction by a jet of steam or air, so that the slag flows off the surface. The slag is then washed away by a stream of water and escapes from the bottom of the furnace under a pivoted door provided with fixed side wings for the exclusion of air and sealed with water along its bottom edge.—H. Hg.

Furnaces for fuel in dust or powdered form. F. Oertel. E.P. 171,118, 7.11.21. Conv., 6.11.20.

A JET of pulverised fuel and air enters a combustion chamber in a vertical direction and tangentially to the curved roof of the chamber. Due to the curvature of the roof and wall of the chamber the flame is reverted in a backward direction, and ash is separated by centrifugal force. There is an opening for the reception of ash at the base of the chamber, and the burning gases are directed over this opening and then across the stream of fuel and air issuing from the jet.—H. Hg.

Coke ovens; Recuperative ——. E. Piron. E.P. 185,811, 2.6.21.

GAS is admitted in a downward direction to each vertical heating flue of a coke oven through a carborundum nozzle at a point below the air inlet. Alternating with the heating flues are vertical flues up which air passes from the recuperators. The tops of all the adjacent heating and air flues are interconnected by a horizontal passage. The gas nozzles and all the passages for air and products of combustion are of large cross-sectional area so that increased supplies of gas and air may be drawn automatically into any relatively cold flue. The recuperator is composed of vertical flues arranged in blocks separated by continuous vertical joints. Each block is constructed of L-shaped bricks laid in opposite directions in alternate courses.—H. Hg.

Carbonising fuel in vertical retorts. Woodall, Duckham and Jones (1920), Ltd., and A. McD. Duckham. E.P. 185,461, 3.5.21.

THE temperature of the coke in the lower part of a vertical retort to which steam is admitted is maintained by the admission of oxygen together or alternately with the steam. The oxygen may be diluted with a proportion of nitrogen determined by the quality of the gas required.—H. Hg.

Retort for gas furnaces. G. Horn. U.S.P. 1,429,346, 19.9.22. Appl., 1.9.21.

A RETORT for manufacturing gas comprises stepped overlapping trough-shaped floor pieces of the breadth of the whole retort in combination with narrow ceiling pieces, each provided at each lateral surface with a groove and placed side by side, above the floor, so as to form an arched ceiling. The groups of the ceiling pieces are placed end to end, the ends of the individual pieces being displaced to the extent to which the floor pieces overlap. The grooves in the lateral surfaces register with each other, and the channel so formed is filled with refractory mortar.—A. R. M.

Gas producers [*and retorts*]. J. Healy. E.P. 185,685, 8.12.21.

Tar is eliminated from the gas produced in generators or retorts by withdrawing the gas through conduits which are subjected to the highest temperature of the fuel. Gas produced in a generator enters the open end of a vertical conduit just above the fuel level, passes into a horizontal conduit which encircles the hot zone of the fuel bed, and then into an off-take. The conduits are constructed of refractory material, provided with cleaning doors and sealed pipes for the removal of carbon, and so arranged as not to interfere with the passage of the fuel.—H. Hg.

Water gas; Apparatus and process primarily intended for manufacture of carburetted —— but which may be used for manufacture of other gases such as "blue" water gas, methane-hydrogen, and producer-gas. E. F. Murray. E.P. 185,887, 1.7.21.

In a gas producer of the type in which a retort is mounted above a water-gas generator, operated on the usual "blow" and "run" system, the gases produced during the blow are burnt in flues around the retort, and those produced during the run are passed through the fuel contained in the retort. A space is formed at the top of the retort for the purpose of drying the fuel and distilling off the lighter volatile constituents by means of the sensible heat of the "run" gas. Such volatile portions are passed into carburetting chambers situated so as to receive heat from the generator, which serves to crack them into permanent gases. If desired, additional carburetting material may be introduced into the vaporising space at the top of the retort. The gases thus fixed pass up through the retort together with the "run" gases and thence into an annular space around the retort, which is exposed to the heat of combustion of the "blow" gas. In this manner all the hydrocarbon vapours of the "run" gas are converted into permanent gases. Provision is made for alternate up-runs and down-runs.—A. R. M.

Gas producer. A. L. Galusha. U.S.P. 1,429,578, 19.9.22. Appl., 28.5.20.

The fuel is deposited on the end of a travelling conveyor which traverses an elongated combustion chamber from end to end. The gases which are driven off by the heat of combustion of a portion of the fuel at the delivery end are led off through an outlet.—A. R. M.

Gas purification; Process and apparatus for ——. K. Cox, R. P. Kerr, and E. J. Baty. E.P. 185,780, 7.4.21.

In a modification of the Klaus process for removing hydrogen sulphide from gases with recovery of sulphur, the temperature of the reaction in the contact material is controlled by suitable heat-exchanging devices, *e.g.*, zigzag pipes or members of cellular or honeycomb form through which steam or other fluid at suitable temperature is passed. The mass of contact material is divided by the heat-exchanging devices into comparatively small sections, but the aggregate cross-sectional area of the material normal to the direction of the flow of the gas is considerable. Thus, the transfer of heat, in conjunction with the heat of reaction, maintains a uniform temperature throughout, sufficiently high to ensure that the free sulphur is carried forward to condensers or receptacles. The gas outlet passage may be kept at such a temperature as to prevent the deposition of sulphur therein by jacketing it with the fluid used to maintain the temperature of the reaction. A great reduction in the size of plant required for purification of a given volume of gas as compared with the usual method is claimed.—A. R. M.

Natural gas; Process of treating —— and product thereof. H. E. Thompson, Assr. to Carbide and Carbon Chemicals Corp. U.S.P. 1,429,175, 12.9.22. Appl., 29.8.21.

A liquid of predetermined vapour pressure is obtained from a mixture of natural gas hydrocarbons by first separating from the mixture a fraction having a higher vapour pressure than that desired and then rectifying this fraction to produce vaporous and liquid portions, the rectification being so conducted that not more than one hydrocarbon of the fraction will occur in substantial quantity in both the liquid and the vaporous portions. Gasoline having a density not less than 87° B. (sp. gr. 0·645) and a vapour tension not substantially greater than 12 lb. at 100° F. (38° C.) can thus be recovered.—T. A. S.

Hydrocarbons or other oils; Apparatus for cracking ——. A. A. F. M. Seigle. E.P. 185,140, 24.2.21.

Hydrocarbon oil is vaporised at 650° C. and a pressure of 12 hectogrammes per sq. cm. (about 17 lb. per sq. in.) in a tube. This tube is packed with aluminium and iron turnings, the portions packed with aluminium being heated only to 450° C. The vapours are then expanded and cooled in chambers packed with metal turnings. Iron turnings are active at 650° C., aluminium at 450° C., copper at 300°—500° C., and ferronickel at 200°—350° C. The expansion chambers are maintained at the desired temperatures by jacketing with water boiling under the necessary pressure. Two expansion chambers are used, one working at 260° C. and the other at 160° C. Some heavy oil condenses in the expansion vessels and is withdrawn from the bottom. The vapours enter the first expansion chamber at the temperature and pressure at which they leave the vaporising tube and leave the chamber at about 260° C. and 4 hg. per sq. cm. (about 5·7 lb. per sq. in.). They are then again compressed and enter the second chamber at 300° C. and 9 hg. per sq. cm. (about 12·7 lb. per sq. in.), leaving at 160° C. and 2 or 3 hg. per sq. cm. (2·8—4·3 lb. per sq. in.). The products of the apparatus are rich gas, light hydrocarbons, and heavy oils suitable for use as lubricants. The quantity of light hydrocarbon can be increased by using suitable catalysts in the second expansion chamber and re-passing through it some of the rich gas along with hydrogen. The apparatus is designed to work on oil not boiling below 200°—250° C.—T. A. S.

Cracked petroleum oils and process and apparatus for producing same. L. W. Goold. From Universal Oil Products Co. E.P. 185,439, 11.3.21.

Oil is cracked at a temperature lower than 875° F. (470° C.) and a pressure of 135 lb. per sq. in. by being circulated in a system consisting of a heating coil about 400 ft. long, built up from 20-ft. sections of 4-in. pipe, and an expansion chamber made up of four 20-ft. sections of 10-in. pipe. Any deposition of carbon takes place in the expansion chamber, which is readily accessible for cleaning. The vapours from the expansion chamber are led off to a dephlegmator and any reflux condensate is taken back to the heating coil. Working on crude oil residues, a pressure distillate is obtained having a lower percentage of unsaturated hydrocarbons than the charging stock and containing not less than 15% each of gasoline and kerosene.—T. A. S.

Oil-cracking process and apparatus therefor. C. A. Jensen. From J. A. Stone. E.P. 185,624, 27.8.21.

The apparatus consists of two concentric cylinders packed with catalytic absorbent or spreading material. Oil is cracked in the inner cylinder, the outer cylinder being gas-fired for heating purposes. When the inner cylinder ceases to operate owing to deposition of carbon etc., the oil to be cracked is introduced into the outer cylinder and the inner cylinder is fired for heating purposes. The apparatus can be made to work with or without pressure. Suitable catalytic materials are cast-iron or nickel or porous fireclay or fuller's earth. Efficient double-phase cracking is claimed.—T. A. S.

Cracking hydrocarbons; Process of and apparatus for ——. F. G. Niece. E.P. 185,632, 7.9.21.

Heavy oil is cracked by passing it through molten metal under pressure. The metal, *e.g.*, lead, is contained in a long vertical tube, and preheated oil is introduced at the bottom. The vapours from the apparatus are condensed under pressure and any uncondensable gases are returned to the lower portion of the cracking apparatus and passed through the molten metal along with the oil under treatment. Distribution of the oil and vapours in the molten metal is brought about by means of baffles. —T. A. S.

Oil-topping plant. B. Gallsworthy. U.S.P. 1,428,159, 5.9.22. Appl., 14.7.19.

Hot flue gases are passed through coils arranged in a still. Oil is sprayed on to the upper coils and caused to drip on to the lower ones by means of baffles. The outlet for unvaporised oil is arranged so that the bottom coil is continually immersed. —T. A. S.

Dehydrator [; Electrical —— for oil emulsions]. W. Meredith, Assr. to Petroleum Rectifying Co. U.S.P. 1,428,178, 5.9.22. Appl., 28.10.20.

An emulsion is treated in a vessel divided into upper and lower compartments by a dielectric diaphragm through which an electrode passes. The electrode is insulated in the upper compartment by an ordinary insulator and also by dehydrated oil. The emulsion is dehydrated in the lower compartment by a high-potential discharge between the electrode and the walls of the vessel.—T. A. S.

Emulsions of petroleum; Apparatus for treating natural ——. W. S. Barnickel. U.S.P. 1,428,204, 5.9.22. Appl., 5.8.18.

The emulsion and a treating fluid are pumped together through a steam-heated conduit to a settling tank. The mixture is agitated during its passage through the conduit.—T. A. S.

Oils; Oil-converting process and apparatus for conversion and transformation of ——. J. H. Adams, Assr. to The Texas Co. U.S.P. 1,428,311-2, 5.9.22. Appl., 25.6.18.

(a) Hot high-boiling hydrocarbons are sprayed by means of superheated steam into a chamber, the steam being heated to a temperature sufficient to crack the oil. The heavy residues are collected in the bottom of the chamber and the evolved lighter vapours are withdrawn from the upper portion. (b) Hot oil is sprayed along with superheated steam into an expansion device consisting of spaced chambers with a communicating passage, the passage being heated. The cracked vapours are removed through a condenser. The apparatus is maintained at a pressure higher than atmospheric. —T. A. S.

Hydrocarbon oils; Apparatus for and method of cracking ——. F. T. Manley, Assr. to The Texas Co. U.S.P. 1,428,338-9, 5.9.22. Appl., 10.10.17.

(a) Oil is cracked by heating in a vertical still under pressure. Fresh oil is introduced into the bottom portion of the still, which is kept cold. The vapours evolved are passed through a dephlegmator, the heavy portions being returned to the bottom of the still with the fresh oil. (b) Hydrocarbon oils of comparatively low boiling point are brought in contact with a body of hydrocarbon oil of higher boiling point, of considerable length relative to its width and heated to a temperature sufficiently high to crack the lower-boiling oil. The vapours of the lower-boiling oil are caused to pass along the surface of the higher-boiling oil, and overheating is prevented.—T. A. S.

Hydrocarbons from oil shale; Process and apparatus for recovery of ——. C. W. Thompson. U.S.P. 1,428,458, 5.9.22. Appl., 15.9.19.

The shale is heated by external means to remove gasoline and light oils, which are collected separately. It is then further heated to vaporise the heavy hydrocarbons, and the vapours evolved are used to preheat cold shale prior to the first heat treatment.—T. A. S.

Compounds preferably of a hydrocarbon nature; Method and apparatus for treating or converting ——. W. J. Knox, Assr. to E. D. Warren. U.S.P. 1,428,641, 12.9.22. Appl., 24.3.19.

Hydrocarbon vapours are cracked by heating to a high temperature. The hot cracked gases before condensation are passed over the surface of oil to preheat it and remove low-boiling constituents. —T. A. S.

Liquid fuel; Method of forming a ——. A. Hayes, Assr. to U.S. Industrial Alcohol Co. U.S.P. 1,428,885, 12.9.22. Appl., 5.6.19.

A mixture consisting mainly of heavy hydrocarbon oil and alcohol and containing small proportions of light hydrocarbon and ether is converted into a fuel of a non-stratifying character by vaporising it and passing the vapours through a finely divided zinc or nickel catalyst maintained at a temperature below about 300° C.—T. A. S.

Hydrocarbons and their derivatives; Process for making —— by heating coal or hydrocarbons with hydrogen. S. Löffler. G.P. 303,332, 1.4.15.

Before being introduced into the reaction vessel the hydrogen and the substances to be hydrogenated are both heated in heat-interchangers to a temperature just below that required for the reaction, solid substances being finely powdered and mixed with liquid reagents. The overheating of the reacting substances and of the walls of the reaction vessel is in this way avoided.—H. C. R.

Naphthasulphonic acids; Extraction of —— produced in the refining of mineral oils with acids. Oelwerke Stern-Sonneborn A.-G. G.P. 310,701, 13.2.14.

Mineral oils or petroleum distillates, after purification by treatment with concentrated or fuming sulphuric acid and subsequent removal of the acid tar, are washed with a mixture of alcohol and aqueous sodium hydroxide. A volatile liquid soluble in water, such as methyl alcohol, ethyl alcohol, or acetone, is added to the lower layer of wash-liquor, and, after removing the mineral oil precipitated from the solution, the volatile liquid is separated by distillation, and naphthasulphonic acids are precipitated from the residue by the addition of acids.—L. A. C.

Sludge acids [from oil refining]; Method of treating ——. I. Hechenbleikner and T. C. Oliver, Assrs. to Chemical Construction Co. U.S.P. 1,429,140, 12.9.22. Appl., 7.1.22.

Sludge acids or separated sludge acids are preheated, without concentration, to drive off the volatile impurities and then concentrated by further heating.—T. A. S.

Coke; Plant for separating —— from waste fuel and residues. W. Weber, Assr. to Weber u. Co., Ges. für Bergbau, Industrie und Bahnbau. U.S.P. 1,429,987, 26.9.22. Appl., 27.12.20.

See E.P. 155,269 of 1920; J., 1921, 837 a.

Coke-oven; By-product —— with sole firing. Sole-heated coke oven. B. Zwillinger. U.S.P. 1,428,621–2, 12.9.22. Appl., 22.3.19, and 24.2.20.

See E.P. 172,739 of 1920; J., 1922, 130 a.

Coke-oven wall. O. Piette, Assr. to Belgian American Coke Ovens Corp. U.S.P. 1,429,252, 19.9.22. Appl., 6.11.18.

See E.P. 120,201 of 1918; J., 1919, 808 a.

Gas generator and retort apparatus; Combined ——. Combined vertical retort and gas-generator apparatus. G. P. Lewis. U.S.P. 1,430,452–3, 26.9.22. Appl., 13.2.22.

See E.P. 177,556 and 177,559 of 1920; J., 1922, 362 a.

Dehydrator [for petroleum emulsions]. F. W. Harris, Assr. to Petroleum Rectifying Co. U.S.P. 1,430,300, 26.9.22. Appl., 7.9.20.

See E.P. 175,352 of 1920; J., 1922, 244 a.

Gas producers [; Fuel rakes of ——]. W. Climie. E.P. 185,980, 15.6.21.

Refrigeration process and machine. E.P. 185,607. *See* I.

Sulphur from spent gas-purifying material. G.P. 357,033. *See* VII.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Activated carbon; Suitability of different coals and vegetable matter for the preparation of ——. F. Fischer, H. Schrader, and K. Zerbe. Brennstoff-Chem., 1922, 3, 241—244.

The wash oil process in practice may still leave one-third of the benzol in the gas, but the use of activated carbon, though more effective, is too costly and the working life too short. Various raw materials have been examined to see if supplies can be obtained so cheaply as to permit the discarding of the carbon after the activity has been impaired, *e.g.*, by deposition of tar. A variety of vegetable substances and coals were examined but only the lignites yielded a product comparable with that obtained from cellulose. The activity of the lignite coke could be improved by pressure extraction of the raw material with benzene. Alexandria lignite carbonised at 800° C. in steam yielded a coke capable of absorbing from air saturated with benzene 22·1% of its weight as compared with 25·3% for charcoal from cellulose.
—H. J. H.

Patents.

Dissolution of wood and other cellulose-containing materials of vegetable origin; Process for the ——. Rütgerswerke A.-G., and H. Teichmann. E.P. 160,467, 4.3.21. Conv., 17.3.20.

Wood in the form of dust or shavings is mixed with about 5 times its weight of anthracene or similar coal tar oil and heated to about 300° C. An alkali may be added to combine with the acids produced, or a mineral acid may be used if the raw material contains nitrogen. The mixture is stirred and the volatile products are passed into a condenser. The insoluble residue is separated from the tar by filtration. Acetic acid, methyl alcohol, creosote, etc., are recovered from the filtrate, and there remains a pitch-like residue soluble in tar oils.
—H. Hg.

Retorts for the distillation of coal and other carbonaceous substances. Low Temperature Carbonisation, Ltd., Low Temperature Construction, Ltd., and T. M. Davidson. E.P. 185,778, 21.3.21.

The plates mounted centrally within a vertical retort as described in E.P. 161,608 (J., 1921, 380 a) are pivoted on a spindle at the top of the retort. There are transverse flanges on the inner faces of the plates which abut one against the other and keep the plates spaced apart during the carbonisation period. Upon rotation of the spindle through 90° the plates move away from the carbonised charge, one in an upward direction and one in a downward direction. The spindle may take the form of a pivoted beam so shaped as to prevent the entry of fuel to the space between the plates while the retort is being charged.—H. Hg.

Low temperature carbonisation; System of ——. J. A. Yeadon. E.P. 185,684, 5.12.21.

Powdered coal is fed into, and coke discharged from, a vertical retort through horizontal cylinders as described in E.P. 114,971 (J., 1918, 295 a). The charging cylinder is heated on its underside by steam or by waste heat from the retort setting, and at its outlet end a rotary distributor is fitted to cause the coal to descend the retort in a fine spray. The coal is heated to 400°—700° C. in the retort, which is of oblong cross-section and provided with internal corrugations as described in E.P. 127,986 (J., 1919, 565 a). The discharge cylinder is water-jacketed.—H. Hg.

Carbon for hardening steel and iron; Process for obtaining extracts and —— from nitrogenous organic matter. M. Lindner. G.P. 357,226, 11.9.20. Addn. to 287,665 (J., 1916, 258).

The process of heating the organic matter in an autoclave under pressure is carried out in the presence of oxygen and carbon dioxide. The yield of extract is in this way considerably increased, the ratio of extract to carbon being 60:40 instead of 20:80 as in the earlier process.—H. C. R.

Gas-tight seals or closures between metals and vitreous materials [quartz]; Production of ——. The Silica Syndicate, Ltd., and F. Reynolds. E.P. 185,952, 7.9.21.

Two or more wires are passed through separate holes in a cylinder or plug of vitreous material, such as quartz or silica glass, the cylinder or plug is fused into an enveloping tube of quartz or silica glass, and the seal completed with lead in accordance with E.P. 23,854 of 1913 (J., 1914, 571).
—J. S. G. T.

Incandescence bodies; Production of —— from tungsten. Bergmann-Elektrizitäts-Werke A.-G. G.P. 355,335, 14.11.12.

In manufacturing incandescence bodies by compressing and heating coarse tungsten powder, finely crystalline tungsten powder is added in place of the usual organic binders, thereby facilitating the sintering of the compressed mass.—L. A. C.

Retorts for distillation [*of bituminous materials*]. Deutsche Petroleum A.-G., S. Kacser, and E. Bauer. E.P. 165,724, 23.6.21. Conv., 3.7.20.

See G.P. 350,572 of 1920; J., 1922, 456 A.

III.—TAR AND TAR PRODUCTS.

Phenols of low-temperature tars. A. Weindel. Brennstoff-Chem., 1922, 3, 245—249. (*Cf.* J., 1920, 150 A, 151 A.)

The tar acids from low-temperature tar produced in the Dellwik-Fleischer "Trigas" process have been examined with a view to their identification. The tar acids were separated and fractionated within close limits. The carbon and hydrogen contents of these fractions were compared with the figures for known phenols. The low hydrogen contents point to the presence of unsaturated and polyhydric phenols. An alternative method was the determination of the molecular weights of the phenol acetic esters, which gave confirmatory results. β-Naphthol was identified.—H. J. H.

Pyridine; Test for ——. F. Lehner. Chem.-Zeit., 1922, 46, 877.

If a few drops of aniline are added to a solution of pyridine containing water and a trace of freshly prepared cyanogen bromide, a red colour is immediately obtained and crystals of α-anilidophenyldihydropyridine bromide separate. Pyridine can be thus detected at a dilution of 1:350,000.—H. C. R.

Patents.

Anthraquinone; Purification of ——. H. F. Lewis, Assr. to National Aniline and Chemical Co., Inc. U.S.P. 1,429,514, 19.9.22. Appl., 22.12.20.

Crude anthraquinone is purified by crystallisation from comercial *o*-dichlorobenzene.—L. A. C.

Phenols and the like; Method of manufacturing ——. R. Pocius. U.S.P. 1,430,184, 26.9.22. Appl., 17.7.20.

In the manufacture of compounds containing the hydroxyl group, *e.g.*, phenols, by fusing other compounds with a quantity of a hydroxide in excess of that required for the reaction, the liquor containing the excess hydroxide is concentrated for use in further fusions.—L. A. C.

IV.—COLOURING MATTERS AND DYES.

Phenanthraquinone; Dyes derived from ——. *I. Phenanthranaphthazines.* A. C. Sircar and S. Dutt. Trans. Chem. Soc., 1922, 121, 1944—1951.

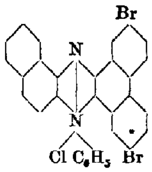
Nitro- and bromo-substituted phenanthraquinones, condensed with 1.2-naphthylenediamine and its 5-sulphonic acid in glacial acetic acid solution, give a series of azine dyes which dye yellow shades on wool, light in the case of the bromo- and deeper in that of the nitro-derivatives. Condensation of 1.2-naphthylenediamine with amino- and hydroxy-substituted phenanthraquinones gives azines, insoluble in water, but soluble in organic solvents, which dye wool from acid baths in shades varying from light yellow to dark brown. They are characterised by high melting point, sparing solubility in organic solvents, well-developed tinctorial properties, and stability to oxidising agents. The dyeing properties of dihydroxydihydrophenanthranaphthazines are unsatisfactory. Ullmann's reaction for the replacement of bromine atoms by anilino groups (Ber., 1901, 34, 2174) can be applied in the phenanthraquinone series. The anilino derivatives so obtained in general dye blue shades, while the corresponding azines without the anilino group dye redder shades. 2.7-Dianilinophenanthranaphthazine,

$$(NH.C_6H_5)_2.C_{14}H_6\langle N_2 \rangle C_{10}H_6,$$

and the 4-nitro-5-anilino-, dinitroanilino- and nitrodianilino-phenanthranaphthazines prepared in this way dye wool in full shades ranging from olive green to bottle green. They are insoluble in water and nearly so in organic solvents. The introduction of sulphonic groups into the azine molecule gives sodium salts, soluble in water, which dye wool from an alkaline bath in brown to maroon shades, the shade being deeper than is obtained with the unsulphonated compound.—P. V. M.

Phenanthraquinone; Dyes derived from ——. *II. Naphthaflavindulines.* S. Dutt. Trans. Chem. Soc., 1922, 121, 1951—1955.

2.7-Dibromonaphthaflavinduline (see formula)



and the 2.7-dianilino-, 3-bromo-, 3-anilino-, 2.7-dinitro-, 4.5-dinitro-, 2-nitro-, 4-nitro-, 2.7-diamino-, 4.5-diamino-, 2-amino, 4-amino-, 2.7-dihydroxy-, 4.5-dihydroxy-, 2-hydroxy-, 4-hydroxy-, dibromonitro- and bromodinitro-naphthaflavindulines, prepared in most cases by condensing the corresponding phenanthraquinone derivatives in acetic acid and nitric acid solution with phenyl-1-amino-β-naphthylamine, exhibit dyeing properties in general much better than those of the corresponding phenanthranaphthazines (*cf. supra*). Freshly prepared, they dye wool evenly from an acid bath. They are difficultly crystalline, and are decomposed with difficulty by fuming nitric acid; they dissolve in concentrated sulphuric acid with a brown colour.
—P. V. M.

Red sulphide dyes; Attempts to prepare ——. E. R. Watson and S. Dutt. Trans. Chem. Soc., 1922, 121, 1939—1943.

Attempts to prepare red sulphide dyes of the azine, oxazine, phthalein, nitroso, and acridine series failed. 2-Amino-8-thiol-10-phenylphenazonium hydroxide,

$$NH_2.C_6H_3\langle N,\ N(C_6H_5)(OH) \rangle C_6H_3.SH,$$

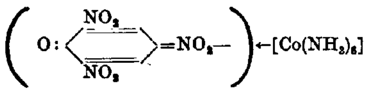
gives dull violet shades sensitive to acids and alkalis; 9-dimethylamino-2-thiol-3-phenoxazone,

$$(CH_3)_2N.C_6H_3\langle N,\ O \rangle C_6H_2(SH):O,$$

gives light indigo-blue shades, and a product (2.8-diamino-3.7-dithiolacridine?), prepared by boiling 2.2′.4.4′-tetra-amino-5.5′-dithioldiphenylmethane, $CH_2[C_6H_2(NH_2)_2.SH]_2$, with ferric chloride and hydrochloric acid, gave light brown shades on cotton. Dithiolfluorescein, obtained by condensation of thiofluorescein and phthalic anhydride, and possibly identical with the compound previously prepared by Maki (J., 1921, 143 A) from fluorescein and sodium sulphide, and dinitrosothiolresorcinol are soluble in sodium sulphide but have no affinity for cotton.—P. V. M.

Cobaltammine salts of the nitro-dyes. Researches on residual affinity and co-ordination. IX. G. T. Morgan and H. J. S. King. Chem. Soc. Trans., 1922, **121**, 1723—1729.

Unlike the mordant dyestuffs of the quinoneoxime, alizarin, and hydroxyazo series, the substantive nitro-dyestuffs do not furnish chelate groups, each capable of reacting as two associating units in the co-ordination sphere of the cobaltic atom. This behaviour of the nitro-dyestuffs may be assigned to a lack of residual affinity in the nitro groups as regards cobalt, or it may be taken as corroborative evidence of the *p*-quinonoid configuration of these substances, hexammino-cobaltic picrate, for example, being formulated



A number of cobaltammine compounds of picric acid, dipicrylamine, 2.4-dinitro-α-naphthol (Naphthol Yellow N), and 2.4-dinitro-α-naphthol-7-sulphonic acid (Naphthol Yellow S) were prepared and are described. The cobaltammine picrates were crystalline compounds, sparingly soluble in cold water to yellow solutions, undergoing partial hydrolysis on warming. The dipicrylamine salts were red non-crystallisable solids, somewhat more soluble in water than the cobaltammine salts of other nitro-dyestuffs. The cobaltammine salts of Naphthol Yellow N were formed as pasty non-crystalline precipitates, brick red in colour when dry. Only dicobaltammine salts of Naphthol Yellow S could be obtained. They were orange, crystalline hydrated compounds, sparingly soluble in water.

Reductions with cadmium in analysis. Treadwell and others. *See* XXIII.

Patents.

2.3-Hydroxynaphthoic acid arylides; Manufacture of sulphonic acids of ——. Farbw. vorm. Meister, Lucius, und Brüning. E.P. 183,428, 23.5.22. Conv., 19.7.21.

By heating with sulphuric acid monohydrate for a short time to 90° C. the arylamides of 2.3-hydroxynaphthoic acid are converted into sulphonic acids which are valuable as dyestuff intermediates. The acids are light grey powders; the solutions in hot water sometimes solidify to a jelly on cooling. The alkali salts are soluble in water to a faint yellow solution.—G. F. M.

Triarylmethane colouring matters; Manufacture of new ——. British Dyestuffs Corp., Ltd., A. G. Green, K. H. Saunders, and S. C. Bate. E.P. 185,612, 17.8.21.

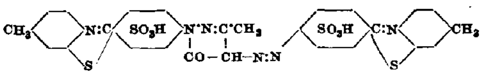
New triarylmethane dyestuffs containing an oxyalkyl group attached to nitrogen are obtained by condensing Michler's ketone or Michler's hydrol with a hydroxyalkylarylamine, a dihydroxyalkylarylamine, a hydroxyalkylalkylarylamine, or a hydroxyalkylaralkylarylamine, and in the case of the hydrol oxidising the leuco compound first produced to the dyestuff in the usual way. *Example.* The hydrochloride of hydroxyethyl-tetramethyl-triaminonaphthyldiphenylcarbinol,

$$[(CH_3)_2N.C_6H_4]_2:C:C_{10}H_6:NHClC_2H_4OH,$$

is obtained by adding 23 pts. of oxyethyl-α-naphthylamine to the product of the action of 20 pts. of phosphorus oxychloride on 30 pts. of tetramethyldiaminodiphenyl ketone (Michler's ketone) in presence of toluene as diluent. The dyestuff crystallises on cooling in green crystals which have the same properties as Victoria Blue R, except that the solubility is much greater. The hydrochloride of tetramethyl-dihydroxyethyltriaminotriphenylcarbinol, $[(CH_3)_2N.C_6H_4]_2C:C_6H_4:N(Cl)(C_2H_4.OH)_2$, prepared from Michler's hydrol and dihydroxyethylaniline, and oxidation of the leuco compound with lead peroxide, is a coppery powder which dyes tannin-mordanted cotton bright purple shades. Other shades of purple are obtained by substituting monohydroxyethylaniline, dihydroxyethyl-*o*-toluidine, etc., for the dihydroxyethylaniline above.
—G. F. M.

Direct cotton dyestuffs; Manufacture of ——. British Dyestuffs Corp., Ltd., J. Baddiley, J. B. Payman, and E. G. Bainbridge. E.P. 185,880, 28.6.21.

Pyrazolone dyestuffs containing two arylbenzothiazole residues and capable of dyeing unmordanted cotton in shades fast to light, washing, and ironing, are produced by interaction between 2 mols. of a thiazolehydrazine and 1 mol. of dioxytartaric acid or alternatively by reaction between 1 mol. of a thiazolehydrazine and 1 mol. of ethyl acetoacetate or oxalacetate, the pyrazolone thus formed being subsequently coupled with a diazotised thiazole. For example, a dyestuff of the formula



is formed by the following method. To 335 pts. of the hydrazine compound obtained from dehydrothiotoluidinemonosulphonic acid suspended in water and neutralised with soda ash are added 160 pts. of sodium acetate and 140 pts. of acetoacetic ester, the mixture is boiled under a reflux condenser for 8 hrs., and acidified; the pyrazolone thus obtained (401 pts.) is coupled with the diazo compound from 343 pts. of dehydrothiotoluidinesulphonic acid and the dye salted out.—A. J. H.

Safranines; Preparation of anthraquinonyl derivatives of ——. Akt.-Ges. für Aniln-Fabr. G.P. 355,491, 13.8.19.

Aposafranine derivatives are treated with aminoanthraquinones in the presence of alkalis, and, if necessary, the dyestuffs produced thereby are sulphonated, yielding acid dyestuffs which dye wool from a hydrosulphite vat. The condensation product obtained by heating dimethylisorosinduline chloride, prepared from nitrosodimethylaniline and 2-phenylaminonaphthalene, with 2-aminoanthraquinone and sodium hydroxide in the presence of nitrobenzene, is treated with fuming sulphuric acid, yielding a dyestuff which gives blue shades on wool from a vat. A similar dyestuff is obtained by condensing 2-aminoanthraquinone with isorosinduline, which is prepared from 2-phenylaminonaphthalene and 1-amino-4-diethylaminobenzene-2-sulphonic acid.—L. A. C.

Vat dyestuff of the anthraquinone series; Preparation of a blue ——. E. Kopetschni. G.P. 356,922, 1.5.14.

1-Mercapto-2-aminoanthraquinone or the corresponding disulphide is heated with a substance capable of removing sulphur, *e.g.*, with copper powder in the presence of naphthalene, yielding N-dihydro-1.2.2′.1′-anthraquinoneazine.—L. A. C.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Flax and kindred fibres. Method for distinguishing flax from hemp. C. R. Nodder. J. Textile Inst., 1922, **13**, 161—171.

The fibrillar structure of the fibres is brought into prominence by mounting in a strong solution of calcium chloride which has been slightly tinted with iodine. The fibre thus softened is then squeezed by pressing the cover glass carefully with a scalpel while under observation under the microscope. The various growth-layers of the cell wall thus become widely separated and distinctly visible. The fibrils of the outer layers of the flax and ramie fibres are observed to form a left-handed spiral, while the fibrils of the hemp and jute fibres are arranged in right-handed spirals. Based on this difference a method for distinguishing between flax and hemp fibres, at any stage of manufacture or purification, is proposed. The material is cut up into short pieces and steeped for some minutes in warm water. Single fibres are picked out with a pair of forceps and held over a hot-plate against a dark background. During the wetting the fibres have undergone a rapid twisting movement in accordance with their characteristic fibrillar arrangement, and when they are held at one end while drying this twisting movement is reversed. If the wet fibre be held with the free end pointing towards the observer, flax and ramie fibres describe a clockwise twisting movement when drying, whereas hemp and jute fibres always move in the anti-clockwise direction. This spiral structure of the component fibres may be assumed to have an important influence on the properties of twisted yarns in textile practice.—J. F. B.

Cellulose; Aerobic decomposition of —— by mould fungi. N. I. Kosin. Nachr. Phys.-Chem. Lomonossow-Ges. Moskau, 1921, **2**, 57—98. Chem. Zentr., 1922, **93**, III., 874.

Mould fungi, particularly *Cladosporium*, are capable of attacking cellulose in the presence of air and mineral nutrient salts, with the primary formation of a hexose which is subsequently converted into carbon dioxide. In the course of 256 days, 25% of the cellulose was thus destroyed. Saccharification takes place under the agency of an enzyme which has been isolated. A similar destruction of cellulose takes place in nature during the summer months and sugar is produced.—J. F. B.

Pine oil. Sandqvist. *See* XIII.

Patents.

Impregnation of textile fabric, paper, etc. L. Ubbelohde. G.P. 316,099, 11.8.17. Addn. to 303,324 (J., 1922, 704 A).

The fabric is soaked in solutions of humic acid and other substances extracted from peat or lignite by means of alkalis, and is then treated with a precipitating agent such as alum or ferric sulphate.

—H. C. R.

Mixed fibre textile goods; Production of ——. A. G. Bloxam. From Technochemia A.-G. E.P. 185,238, 4.6.21.

A mixed textile material which appears to contain one kind of fibre only, even when dyed, is made by spinning a mixture of animal fibres, *e.g.*, wool slivers, treated as described in E.P. 183,249 and 183,270 (*cf.* U.S.P. 1,389,274-5; J., 1921, 765 A) with combed artificial cellulose fibres of any degree of fineness in the ratio, for example, of 1:2.

—D. J. N.

Fur and wool; Process for protecting —— from moth and other insects. Vereinigte Chem. Fabr. J. Norden und Co. G.P. 357,063, 25.10.21.

Animal fibres are protected from moth etc. by treatment with the vapour of α-tetralon (α-tetrahydronaphthaleneketone) or mixtures of this with other suitable substances. The protective effect of α-tetralon is more lasting than that of chlorinated aromatic compounds, since it is less volatile. α-Tetralon is obtainable as an emulsion in soft soap or in the form of a powder, pellets or tablets. Paper and fabrics may be treated with solutions of α-tetralon in petroleum spirit of high boiling point.

—A. J. H.

Viscose; Preliminary treatment of cellulose intended for the manufacture of ——. W. Cross. From Technochemia A.-G. E.P. 185,433, 4.3.21.

Bleached or unbleached sulphite or soda wood pulp is treated with 0·5% hydrochloric acid at 100° C., or with 2% hydrochloric acid at 80° C., or 8% hydrochloric acid at 40°—50° C., or with 0·2% sulphuric acid in a closed vessel under a steam pressure of 0·5 atm. for several hours. The digested cellulose is washed free from acid and transformed into viscose by treatment with only 30—40% of the quantities of sodium hydroxide and carbon bisulphide usually required. Under the conditions specified, if no drying of the cellulose be permitted, there is no formation of hydrocellulose as measured by solubility of the treated cellulose in boiling barium hydroxide solution.—J. F. B.

Nitrocellulose composition [for films]. A. F. Sulzer, Assr. to Eastman Kodak Co. U.S.P. 1,429,174, 12.9.22. Appl., 23.2.21.

A liquid composition for forming film by flowing and drying consists of nitrocellulose 100 pts., a monohydric aliphatic alcohol having 4 to 5 carbon atoms 10 to 100 pts., ethyl butyrate 1 to 100 pts., and sufficient common solvent to make a viscous solution.—T. A. S.

[Cellulose ether] films; Process of treating ——. W. R. Webb, Assr. to Eastman Kodak Co. U.S.P. 1,429,179, 12.9.22. Appl., 4.11.21.

The curling tendency of a film containing cellulose ether is lessened by applying a solvent to the face of the film and stopping the application before the body of the film is attacked.—T. A. S.

Pyroxylin composition and process of making the same. W. G. Lindsay, Assr. to The Celluloid Co. U.S.P. 1,430,020, 26.9.22. Appl., 16.2.20.

A pyroxylin composition having a high degree of flexibility consists of 100 pts. of nitrocellulose and more than 60 pts. of an aromatic phosphate.

—A. J. H.

Ethers of carbohydrates; Production of ——. G. Young. E.P. 184,825, 12.9.21.

Alkyl ethers of carbohydrates of the general formula $(C_6H_{10}O_5)_n$, *e.g.*, cellulose, starch, and dextrin, are made by heating the carbohydrate (1 mol. $C_6H_{10}O_5$) in admixture with approximately 1—1½ times its weight of a metallic hydroxide, preferably sodium hydroxide, and 0·5—0·75 times its weight of water, with about 20 mols. of an alkyl chloride, *e.g.*, methyl, ethyl, propyl, or amyl chloride, in a revolving autoclave for 6—8 hrs. at 100°—150° C. (preferably not above 130° C.). A convenient method of mixing the carbohydrate with alkali is to soak the carbohydrate for 30 mins. in a 40% solution of alkali, and then gently squeeze out the excess of solution. When methyl or ethyl chloride is used as the alkylating agent, it is introduced into the autoclave by means of a pressure pump and the reaction proceeds sufficiently rapidly at 100° C. Inert diluents such as benzene, and catalysts, such as finely divided copper, may also be used. When etherification is complete, the unchanged alkyl chloride is removed by distillation, excess of alkali is removed by washing with water, and the product purified by solution in glacial acetic acid and precipitation by water. Good yields are obtained and the ethers produced are insoluble in benzene, methyl or ethyl alcohol, but soluble in glacial acetic acid; they may be used for the manufacture of artificial threads, films, plastic masses, etc.—D. J. N.

[Sulphite] pulp boilers; Recovery of sulphurous acid and heat from the waste gases from ——. Process of filling pulp boilers with heated sulphite lye. (A) Zellstoff-fabr. Waldhof, C. Hangleiter, and H. Clemm, (B) Zellstoff-fabr. Waldhof, and H. Clemm. E.P. (A) 167,171 and (B) 168,866, 25.7.21. Conv. (A) 2.8.20, (B) 4.9.20.

(A) Waste gases etc., from sulphite pulp boilers are passed without cooling into raw sulphite liquor contained in a closed lead-lined tank capable of withstanding pressure. The liquor, when sufficiently enriched with sulphurous acid and heated to a temperature of 90° C. or above, is transferred directly to a boiler, freshly charged with wood. (B) Wood pulp boilers are filled with hot sulphite liquor by means of a pressure pump or similar device, the digester being closed by an excess pressure valve which can be adjusted so that for any given temperature the desired quantity of sulphur dioxide is retained in the acid liquor.—D. J. N.

Sulphite pulp digesters; Blowing off of —— with recovery of sulphur dioxide and heat. Zellstoff-fabrik Waldhof. G.P. 350,471, 28.4.21.

The gases and steam discharged from the digesters are condensed in the immediate neighbourhood of the digesters by means of fresh liquor and are absorbed by this liquor.—J. F. B.

Printed papers; Recovery of paper fibres or pulp from ——. S. Kumagae and T. Chiba. G.P. 356,742, 5.10.21.

The waste paper is boiled with a mixture of the residual liquor from the manufacture of "Tofu," with soap and sodium thiosulphate, and the printers' ink is removed in the usual way by washing the pulp. "Tofu" is a Japanese foodstuff prepared from the soy bean.—J. F. B.

Animal and vegetable fibres; Method of rendering —— active. J. Korselt, Assrs. to The Chemical Foundation, Inc. U.S.P. 1,426,298, 15.8.22. Appl., 24.10.17.

See E.P. 108,489 of 1917; J., 1920, 482 A.

Textile materials; Degumming ——. G. Jenny and O. Jaeck, Assrs. to Swiss Ferment Co., Ltd. U.S.P. 1,430,523, 26.9.22. Appl., 16.6.20.

See E.P. 145,583 of 1920; J., 1921, 383 A.

Graphitised vulcanised fibre; Methods of preparing ——. E. G. Acheson, jun. E.P. 174,899, 7.7.21. Conv., 31.1.21.

See U.S.P. 1,379,156 of 1921; J., 1921, 540 A.

Cellulose esters; Production of ——. A. D. Little, Inc., Assees. of G. J. Esselen, jun., and H. S. Mork. E.P. 161,564, 9.3.21. Conv., 10.4.20.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Patents.

Liquid washing blue and bleaching preparation and process for making the same. J. J. Reichelt. E.P. 176,747, 13.6.21. Conv., 8.3.21.

A liquid preparation containing ultramarine and which exerts simultaneously a purifying, bleaching, and disinfecting action is made by heating a mixture containing borax, turpentine oil, alcohol, water-glass, sodium tungstate, formaldehyde, and ultramarine. This preparation is not affected by hard water.—A. J. H.

Cleansing and sterilising textile fabrics and other materials; Preparations for ——. A. Maclennan. E.P. 185,828, 9.6.21.

A powder suitable for cleansing lace curtains, silks, tapestries, carpets, linoleum, etc., and also, in conjunction with a 5% solution of hydrogen peroxide, suitable for removing ink, iodine, and paint stains from fabrics, consists of 53½ pts. of a mixture of equal parts of palm and cokernut (coconut) oils, 31½ pts. of anhydrous sodium carbonate, and 15 pts. of water, together with a further addition of about 2% of ultramarine for the purpose of correcting yellow coloration. In the preparation of this powder, 60 pts. of the mixture of oils is saponified at 38°—45° C. with a strong solution containing 35 pts. of anhydrous sodium carbonate, and the product is allowed to cool and solidify.—A. J. H.

Bleaching and dyeing vegetable and animal fibres; Process of ——. A. S. Roberts, Assr. to Surpass Chemical Co., Inc. U.S.P. 1,429,775, 19.9.22. Appl., 30.3.21.

Textile material is bleached and dyed at the same time in a bath containing a dyestuff, an alkaline oxidising agent, and a neutralising agent. —A. J. H.

Printing; Multicolour ——. F. Kunert and E. Acker, Assrs. to The Chemical Foundation, Inc. U.S.P. 1,426,299, 15.8.22. Appl., 2.11.16.

See E.P. 104,108 of 1916; J., 1917, 384.

Cotton; Process for imparting transparent effects to ——. H. Forster, Assr. to C. Forster. U.S.P. 1,430,163, 26.9.22. Appl., 21.9.20.

See E.P. 162,627 of 1921; J., 1922, 291 A.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Nitrogen oxides; Reactions between gaseous —— and alkaline solutions. A. Sanfourche. Comptes rend., 1922, 175, 469—472.

In estimating gaseous oxides of nitrogen, sulphuric acid is to be preferred to alkali as an absorbent, as the latter, in presence of oxygen, gives too high a figure unless alkali is in excess at all points of contact. If this condition is not fulfilled the formation of nitrite and nitrate is affected by the reaction with water to form nitric acid and nitric oxide, the latter combining with more oxygen. Further, if absorption of the vapour in alkali is incomplete, volatilisation of water causes the reaction to take place in the gaseous phase and free nitric acid is formed as a mist even in presence of alkaline solution.—H. J. E.

Ammonia; Limits for the propagation of flame at various temperatures in mixtures of —— with air and oxygen. A. G. White. Trans. Chem. Soc., 1922, **121**, 1688—1695.

Propagation of flame downwards in mixtures of ammonia with air, determined in tubes of 5 cm. diam. at temperatures from 0° to 450° C., begins when the temperature approaches 70° C., the optimum mixture containing about 22·5% of ammonia by volume, while the mixture for complete combustion contains just under 22%. Up to 140° C. the interval between the upper and lower limits increases very rapidly. Above this point the upper limit increases at the same rate for downward propagation as for propagation in other directions, but the lower limit decreases more rapidly for downward—10% per 100° C.—than for upward or horizontal propagation; for the last-named the decrease appears to be 7% per 100° C. The limits with air determined in tubes of 7·5 cm. diam. are approximately the same for upward as for horizontal propagation. The upper and lower limits for mixtures of ammonium and air at any one temperature are nearly symmetrically situated about the mixture for complete combustion for all directions of propagation. The lower limit for horizontal propagation for ammonia-air mixtures at 18° C. in a tube of 7·5 cm. diam. is 17·4% and for ammonia-oxygen mixtures 15·6%. In determining the upper limit mixtures with oxygen great care had to be taken, as using slightly too little ammonia was apt to cause a violent explosion. Calculation shows that to ensure propagation at the lower limits the flame temperature must be approximately the same —about 1620° C.—whatever the initial temperature of the mixture. Undried air was used in the experiments, since moisture up to 2·5% is without effect on the limit values.—P. V. M.

Sulphurous acid; Autoreduction of ——. G. M. Bennett. Trans. Chem. Soc., 1922, **121**, 1794—1795.

Sulphurous acid, liberated in solution at 100°—120° C. and lower temperatures, by dropping powdered sodium sulphite or metabisulphite, or saturated solutions of these salts into hot aqueous 60—70% sulphuric acid, to which a small quantity of antimonious oxide has been added, undergoes instantaneous autoreduction with formation of hydrogen sulphide. Gaseous sulphur dioxide, the solid hydrate, or saturated solutions of sulphur dioxide gave negative results.—P. V. M.

Carbon dioxide; Rate of absorption of —— by ammoniacal solutions. P. Riou. Comptes rend., 1922, **175**, 472—474.

The author has investigated the rate of absorption of carbon dioxide by solutions of ammonium carbonate containing different proportions of bicarbonate, and expresses his results by diagrams showing velocity as a function of concentration and also of temperature. In the former, the rate of absorption reaches a maximum and then falls off; the presence of bicarbonate renders the action considerably slower. In the latter increasing concentration of bicarbonate in proportion to carbonate lowers the temperature at which the maximum is reached.—H. J. E.

Alkali metal bisulphites; Equilibria in aqueous solutions of ——. E. C. C. Baly and R. A. Bailey. Trans. Chem. Soc., 1922, **121**, 1813—1821.

The equilibrium mixtures of air-free solutions of metabisulphites or of bisulphites contain $K_2S_2O_5$, K, $KHSO_3$, HSO_3, and possibly S_2O_5, hence these solutions show the absorption band, $\lambda=257\mu\mu$ of metabisulphite. Such solutions are stable to light in absence of oxygen, but in the presence of oxygen, photo-oxidation of the HSO_3 ion occurs, followed by an ionic rearrangement whereby normal sulphate, sulphurous acid and hydrated sulphur dioxide are produced. The solution then shows the absorption band at $\lambda=276\mu\mu$ characteristic of hydrated sulphur dioxide. No isomerism of sulphite molecules has been detected.—P. V. M.

Nitrites; Detection of ——. P. Falciola. Gazz. Chim. Ital., 1922, **52**, II., 87—89.

The following reactions serve for the detection of nitrites. (1) Addition of sodium thiosulphate solution, of about 0·5 *N* concentration, drop by drop to an alkali nitrite solution acidified with sulphuric acid yields a transitory yellow coloration, more or less intense according to the proportion of nitrite present; this reaction is perceptible with 0·0001 *N* nitrite solution. With moderately concentrated nitrite solution, use may be made of sodium thiosulphate test-paper, which is dipped first into the nitrite solution and then into dilute sulphuric or acetic acid. (2) If a litre of water containing 0·0001% of sodium nitrite is treated with about 2 c.c. of sulphuric acid and then with excess of thiocyanate and about 0·1 g. of ferrous sulphate, an orange coloration is readily developed; if only 0·00001% of the nitrite is present, the colour appears more slowly. Should pure ferrous sulphate be unavailable, the water to be tested may be treated with a pinch of thiocyanate, and a small glass tube containing a small piece of iron, such as a nail and a little dilute sulphuric acid, added immediately afterwards; the characteristic coloration appears in the neighbourhood of the glass tube if nitrite is present (*cf.* Horst, J., 1921, 507 A). (3) Excess of aniline phosphate, either solid or in freshly prepared solution, gives a yellow coloration, turning to reddish, with a 0·1% sodium nitrite solution and a faint yellow coloration with a 0·01% solution; the reaction is not detectable with a nitrite solution of greater dilution than 0·001%. Benzene removes the colouring matter from the liquid, and the coloration may be distinguished from that given by hydrogen peroxide by means of sulphuric acid, which turns it red or pink. —T. H. P.

Perchlorates; Preparation of —— by heating chlorates. F. C. Mathers and J. W. H. Aldred. Trans. Amer. Electrochem. Soc., 1922, 57—63. [Advance copy.]

A yield of about 55% of potassium perchlorate is obtained by heating potassium chlorate at 480°—550° C., for from 30 min. to 4 hours. The actual period of heating necessary is determined by the temperature and the quantity of chlorate used. No catalytic agents have been found which will increase the yield of perchlorate; silver oxide, red lead, mercuric oxide, and glass materially reduce the yield. Sodium chlorate behaves similarly, but gives smaller yields throughout.—J. B. F.

Alkali iodides; Analysis of ——. L. W. Winkler. Pharm. Zentralh., 1922, **63**, 386—387.

Commercial samples of potassium iodide were found to contain 98·6—99·6% of the salt, whilst the purity of samples of sodium iodide was 97·0—99·9%. —W. P. S.

Alkali formates and acetates; Solubilities of —— in water. N V. Sidgwick and J. A. H. R. Gentle. Trans. Chem. Soc., 1922, 121, 1837—1843.

The solubility of the formates and acetates of the alkali metals, like that of most salts of weak acids, increases with the atomic weight of the alkali metal, though the lithium salt is more soluble than the sodium salt below 120° C. in the case of the formates, and at all temperatures in the case of the acetates. Both the sodium and lithium salts are markedly less soluble than are those of the other alkali metals. The solubilities of the anhydrous salts at 100° C. (that of potassium acetate is of the hydrated salt $C_2H_3OK,\frac{1}{2}H_2O$), in molecular percentages, are:—lithium formate 31·7, lithium acetate 34·9, sodium formate 29·8, sodium acetate 27·2, potassium formate 62·1, potassium acetate 43·0, rubidium formate 67·4, rubidium acetate 51·2, cæsium formate 67·7, cæsium acetate 58·3. Hydrates of the formates and acetates of lithium, sodium, rubidium and cæsium and of potassium acetate are described.—P. V. M.

Chromium trioxide—sulphur trioxide—water; The system ——. L. F. Gilbert, H. Buckley, and I. Masson. Trans. Chem. Soc., 1922, 121, 1934—1938.

By measurement of the solubilities of chromium trioxide at 25° and 45° C. in sulphuric acid of varying concentrations the isothermal diagram of the condensed ternary system, chromium trioxide, sulphur trioxide, water, is shown to have three distinct regions, each with a minimum of solubility. In the first region the solid phase is chromium trioxide, the minimum solubility 0·3% by weight, occurring in 70% aqueous sulphuric acid. In the second region, between 85 and 95% sulphuric acid, the solid phase is CrO_3,SO_3, which above 95% sulphuric acid passes into the compound, CrO_3,SO_3,H_2O characteristic of the third region. Both complex compounds have small solubilities, are very hygroscopic and liberate scarlet chromic oxide on exposure. They tend to become amorphous when deposited from sulphuric acid of high concentration or from fuming sulphuric acid. Equilibrium is attained slowly, at least several days being required.—P. V. M.

Chromate electrolysis with diaphragms. A. Lottermoser and K. Falk. Z. Elektrochem., 1922, 28, 366—376.

Extending the work of Müller and Sauer (J., 1912, 982) the authors have investigated the current yields obtainable in the electrolysis of sodium chromate in diaphragm cells of the following types: (1) With two compartments, (a) catholyte NaOH, anolyte Na_2CrO_4; (b) both electrolytes Na_2CrO_4; (2) with three compartments, (a) catholyte NaOH, in the other two compartments Na_2CrO_4, (b) in all compartments Na_2CrO_4. The yields obtained confirmed theoretical considerations. In the two-compartment cell, case (a). the yields of bichromate and of sodium hydroxide approximated to the theoretical 18%. To some extent the diaphragm acts as a third compartment, causing the yield of bichromate for the first half hour to be much higher. In case (b) the yields of both bichromate and sodium hydroxide are nearly 100% for a time, but soon fall off as the migration velocity of the OH ion comes more and more into play. With a three-compartment cell the best yield is obtained in case (b) and this is the most favourable type for the electrolysis. Technically, however, the difficulty would arise of working up the solution in the middle compartment, in which most of the sodium hydroxide accumulates and from which sodium chromate would have to be separated. The paper concludes with a mathematical investigation of the yields possible under different conditions.—E. H. R.

Potassium permanganate; Properties of ——. G. Fester and G. Brude. Z. angew. Chem., 1922, 35, 527.

Crystals of pure potassium permanganate prepared in the dark and in air free from carbon dioxide and organic matter are brown and have a bronze metallic lustre. The finely powdered crystals however show a dark violet colour. When exposed to subdued daylight and ordinary air, the surfaces of crystals develop a violet colour in a few hours and a steel-blue lustre after two days. This change is confined to the surface layer, which acts as a filter protecting the remainder of the crystal. The change is particularly rapid in an atmosphere containing mineral acid. Potassium permanganate oxidises paper and most other organic substances, so that the statement that it is without action on litmus paper is untrue.—H. C. R.

Hydrogen peroxide; Catalysis of —— by finely divided platinum. Influence of inhibitants. E. B. Maxted. Trans. Chem. Soc., 1922, 121, 1760—1765.

The activity of finely-divided platinum in the catalysis of the decomposition of hydrogen peroxide in the presence of the inhibitants, mercuric chloride, mercuric nitrate, and lead acetate, is, over a wide range, a linear function of the concentration of the poison; the curve is of the same type as that representing the inhibition of the activity of catalysts for the hydrogenation of an ethylene linkage. With higher concentrations of the poison the inhibition of activity is less abrupt, the deviation from the linear curve occuring when slightly less than 75% of the original activity has been suppressed; this corresponds to the presence of about 3% of mercuric chloride, 1% of mercuric nitrate, and 8—9% of lead acetate. With the materials employed the decomposition proceeds approximately according to the unimolecular reaction law.—P. V. M.

Arsenic trichloride; Solubility of —— in concentrated hydrochloric acid at 100° *C.* W. D. Treadwell and C. Mussler. Helv. Chim. Acta, 1922, 5, 818—821.

The solubility of arsenic trichloride in concentrated hydrochloric acid at 100° C. was determined by an indirect method consisting in measuring the rate of volatilisation of the trichloride in a current of gaseous hydrogen chloride from the solution at 100° C. The solubility found was 100·3 g. per litre. To volatilise 99% of the $AsCl_3$ present in 100 c.c. of saturated solution at 100° C. requires 19·8 litres of hydrogen chloride gas; to complete the volatilisation to 1 pt. in 1000 requires 29·7 litres of gas. (*Cf.* J.C.S., Nov.)—E. H. R.

Acetylene and nitrogen; Explosion of ——. II. W. E. Garner and K. Matsuno. Trans. Chem. Soc., 1922, 121, 1729—1736.

Explosion experiments on mixtures of acetylene and nitrogen with hydrogen and helium and of acetylene with cyanogen show that substitution of hydrogen or helium for nitrogen causes a marked increase in the rate of cooling, while the temperature of explosion is higher in the presence of helium than when equal amounts of either nitrogen or hydrogen are present. The yield of hydrocyanic acid is given by the relation

$$[HCN]=K_1''[C][N_2]^{0{\cdot}37}$$

where [C] represents the atomic concentration of carbon per litre of bomb volume. $K_1''=0{\cdot}079$ is found to hold for experiments previously reported (J., 1922, 90 A) and for mixtures containing hydrogen and helium. This indicates that the yield of hydrocyanic acid is practically independent of the partial pressure of the hydrogen, being a function only of the area of carbon surface and the concentration of nitrogen. The expression $[NH_3]=K_2[HCN][H_2]$ approximately represents the concentration of ammonia in the explosion mixture, K_2 being decreased by the addition of helium and increased by the addition of hydrogen to the mixture. Helium thus acts as a negative catalyst. The acetylene which escapes decomposition varies between 8% and 4% in the final gases. In the experiments with mixtures containing cyanogen larger amounts of hydrocyanic acid and ammonia were formed.—P. V. M.

Carbon bisulphide; Manufacture of ——. G. A. Richter. Trans. Amer. Electrochem. Soc., 1922, 219—232. [Advance copy.]

The furnace described consists of a cast iron shell lined with refractory material and fitted with water-cooled electrodes to which power is supplied by a 2-phase 440-volt A.C. line with transformers in 10-volt stages. The resistance bed consists of broken arc light carbons. The sulphur is melted externally by steam and fed into the hottest part of the furnace through a liquid seal. The charcoal (willow or birch) must be well burnt and as dry as possible. The carbon bisulphide is condensed and washed with water. This unit has a capacity of 1 ton of carbon bisulphide per 24 hrs. with a power consumption of 0·5—0·7 kw.-hr. per lb. of washed material recovered, and works with an 80% efficiency on sulphur. The thermal efficiency is discussed in detail. The thermal balances for some steps in the complicated transformation from solid rhombic sulphur to sulphur vapour at 1000° C. are unknown, but making approximations, Thomsen's value of −26,000 cals. for the heat of formation of gaseous carbon bisulphide appears to be about correct. Taking this figure the thermal efficiency of the furnace is about 31%, loss by radiation accounting for another 60%. This loss can be reduced by increasing the size of the unit, but such increase also raises the loss of sulphur by sublimation.—C. I.

Thiocyanates. Chlorides and bromides in presence of thiocyanates. Spacu. *See* XXIII.

Radioactive indicators. Paneth. *See* XXIII.

Patents.

Sulphuric acid; Process for producing the effect of the Glover tower in the manufacture of ——, *without the use of Glover towers.* T. Schmiedel. E.P. 184,966, 12.7.21.

In the lead chamber process, the Glover tower is replaced by a mechanical apparatus of the type described in E.P. 149,647 (J., 1921, 613 A). The gases are cooled and freed from dust, the nitrosylsulphuric acid is denitrated, the chamber acid introduced is concentrated, and a greater part of the sulphurous acid is converted into sulphuric acid by the direct action of nitrosylsulphuric acid (*cf.* E.P. 149,648; J., 1921, 693 A).—J. B. F.

Nitric acid purification; Apparatus for ——. G. H. Tozier, Assr. to Eastman Kodak Co. U.S.P. 1,429,177, 12.9.22. Appl., 24.5.21.

An apparatus for obtaining pure concentrated nitric acid consists of a still, a partially refluxing condenser resistant to the concentrated acid, and a complementary condenser connected in series.
—T. A. S.

Acids; Manufacture of ——. W. O. Snelling. U.S.P. 1,430,035, 26.9.22. Appl., 17.7.20.

A mixture of halogen gas or vapour and sulphur dioxide is exposed to actinic rays whilst being sprayed with an aqueous fluid.—D. F. T.

Sulphurous acid [sulphur dioxide]; Process for the manufacture of ——. Rhenania Verein Chem. Fabr. A.-G., formerly Verein Chem. Fabr in Mannheim. E.P. 161.581, 9.4.21. Conv., 14.4.20.

A mixture of ferric oxide (pyrites cinder etc.) with iron pyrites or similar sulphide in the proportion of 1·5—3·0 mols. of Fe_2O_3 to 1 atom of sulphide sulphur is calcined at 900°—950° C. with an alkaline-earth sulphate. The excess of ferric oxide prevents loss of sulphur by sublimation almost completely.—C. I.

Ammonium chloride [solution]; Treatment of ——. A. Riedel. E.P. 167,769, 10.8.21. Conv., 13.8.20.

Ammonium chloride solution is rendered exactly neutral by allowing it to trickle over lumps of calcium carbonate. It can then be handled in iron vessels without corrosion. If the solution contains iron the limestone treatment causes precipitation of this in a form capable of removal by filtration.
—C. I.

Sulphate furnaces; Mechanically operated stirring devices for ——. R. Moritz. E.P. 172,006, 21.11.21. Conv., 23.11.20.

The teeth of the stirring device are made of ferro-silicon containing 12—16% Si. Such material can be cast into any desired shape, is very hard, and is refractory to acids.—J. B. F.

Compound and method of producing same [by means of selenium oxychloride. V. Lenher. U.S.P. 1,385,081, 19.7.21. Appl., 4.8.20.

The patent covers the general application of selenium oxychloride, alone or mixed with a modifying agent, *e.g.*, sulphur trioxide, as a solvent. Examples mentioned are its use for dissolving oxides of molybdenum, selenium, arsenic, and vanadium; for attacking or dissolving metals and non-metals; for reacting with or dissolving unsaturated hydrocarbons and separating them from aliphatic saturated hydrocarbons; for dissolving rubber, plenol-aldehyde condensation products, etc. (*Cf.* J., 1922, 158 A, 159 A, 751 A).

Treating air and gases electrically; Method of and apparatus for ——. [*Oxidation of nitrogen.*] W. T. Hoofnagle, Assr. to Electro Chemical Products Co. U.S.P. 1,388,112, 16.8.21. Appl., 6.3.20.

Air is passed through a non-disruptive electric field and a catalyst, *e.g.*, water vapour, is introduced into the reaction chamber to facilitate combination of nitrogen and oxygen. The products are passed through an oxidising chamber, and the nitrogen oxides subsequently absorbed. In order to maintain a non-disruptive discharge at relatively high air pressures, the electrodes, which may be of nickel, are heated before supplying them with a high-tension current, or the discharge is first produced between the cold electrodes in a partially exhausted chamber, and the air pressure is gradually increased as the electrodes become heated.—J. S. G. T.

Calcium cyanamide; Preparation of ammonium sulphate from crude ——. Bambach und Co. G.P. 299,131, 7.2.13.

Calcium cyanamido is heated with sodium bisulphate and water, the residue filtered off, and the liquor evaporated. The proportions of the reacting substances are so adjusted that the solution contains more than 1·3 pts. (preferably 3 pts.) of Na_2SO_4 to 1 pt. of $(NH_4)_2SO_4$; on evaporation the whole of the sodium sulphate crystallises out, and by further evaporation of the mother liquor, technically pure ammonium sulphate is recovered direct. If necessary, sodium sulphate is added to the solution before evaporation.—C. I.

Nitrogen-containing compounds [calcium cyanide]; Process for making metal —— augmented by gaseous catalysts. J. H. Reid, Assr. to International Nitrogen Co. U.S.P. 1,388,603, 23.8.21. Appl., 12.9.17.

A METAL carbide associated with a gaseous catalyst (*e.g.*, hydrogen chloride, carbon tetrachloride) is exposed to the action of nitrogen and heat, the temperature being maintained below that at which a metal cyanamide is formed.—H. R. D.

Aluminium chloride crystals; Method of preparing ——. H. Howard, Assr. to The Grasselli Chemical Co. U.S.P. 1,430,449, 26.9.22. Appl., 6.3.22.

A CONCENTRATED solution of aluminium chloride is treated with gaseous hydrogen chloride, and the crystals which separate are freed from adhering acid by washing with basic aluminium chloride solution.

Insoluble precipitates [e.g. of aluminium hydroxide]; Process for the separation of —— from solutions. M. Buchner. G.P. 301,332, 5.6.14.

Two solutions which on interaction yield an insoluble precipitate, *e.g.*, aluminium sulphate and ammonia, are separated by a porous partition. The precipitated aluminium hydroxide is thus deposited on the partition, whilst the ammonium sulphate diffuses through. By continuous addition of ammonia to the solution this may be concentrated until solid ammonium sulphate separates, and the process rendered continuous. Metallic hydroxides deposited in this way are in a granular form.—C. I.

Separation of the elementary constituents of air or other gaseous mixtures; Process for the ——. [Extraction of argon.] L'Air Liquide Soc. Anon. pour l'Etude et l'Exploit. des Proc. G. Claude. E.P. 184,454, 22.7.22. Conv., 12.8.21.

IN the separation, *e.g.*, of argon from air, by liquefaction and rectification, a gaseous mixture containing a considerable proportion of an element (*e.g.*, argon) of boiling-point intermediate between those of the two main constituents of the mixture, is withdrawn from the usual rectifying column, and a quantity of gas is introduced into the column substantially equal to that removed and of the same composition minus the amount, extracted outside of the column, of the element of intermediate boiling-point (*e.g.*, argon) or of gas rich in that element. The gases obtained by vaporising the liquid produced during the rectification of the gases removed from the main column may be returned to the main column and the vaporisation may be utilised to effect the rectification. Alternatively the liquid may itself be returned to the main column at a point below that at which the gases are removed.—H. H.

Gases; Process for separating mixed —— by centrifugal diffusion. Process for separating oxygen and nitrogen from the air by centrifugal diffusion. R. F. Heinrich. G.P. (A) 347,601, 20.12.19, (B) 354,630, 28.11.20.

(A) A MIXTURE of gases flows at high velocity and under high pressure through a stationary or rotating spiral system which is provided with porous walls, constructed of, *e.g.*, earthenware, on the side having the smaller radius of curvature. For example, if air is passed through the apparatus, the heavier oxygen molecules are thrown by centrifugal force against the impermeable wall, while the lighter nitrogen molecules collect against the permeable wall, through which they diffuse into the atmosphere or into a collecting tube. (B) The diaphragm in the apparatus described in (A) is constructed of layers of fine wire gauze with porous material, such as kieselguhr or charcoal, embedded therein, the upper layer of the gauze being in the form of a wire brush with a large number of fine points. The diaphragm is connected with a source of high-tension electric current and the remainder of the apparatus is earthed. In treating air in the apparatus, the oxygen of density 1·1056 (air=1) is converted into ozone of density 1·7, while the nitrogen is unaltered, the greater difference in density increasing the efficiency of the separation. In addition, particles of charcoal in the diaphragm absorb a large quantity of ozone, and this aids in preventing the remainder of the ozone from diffusing through the diaphragm.—L. A. C.

Oxygen; Aqueous solutions containing —— and methods of producing same. O. Y. Imray. From Aquazone Laboratories, Inc. E.P. 185,659, 13.10.21.

COMPRESSED air under a pressure of 130—140 lb. per sq. in., preferably in the form of a jet, is continuously forced through water, which is agitated, for 30—40 min., the temperature being kept about 54° F. (12° C.). The oxygen is preferentially dissolved and the product contains more than 35 c.c. of oxygen per litre of water. Containers are filled with the product under pressure, and hermetically sealed. When the pressure is released several days elapse before the whole of the excess of oxygen has been evolved. The solution has a powerful oxidising action and has valuable therapeutic properties.—J. B. F.

Iodine; Tablet for producing ——. L. Davis, Assr. to Brewer and Co., Inc. U.S.P. 1,429,276, 19.9.22. Appl., 26.11.21.

A SOLID tablet which will liberate iodine on contact with water is compounded of potassium iodide, potassium bromide and bromate, and urea nitrate or analogous compound.—C. I.

Hydrogen; Drying —— by compression and cooling. Berlin-Anhaltische Maschinenbau A.-G. G.P. 300,711, 30.8.16.

HYDROGEN is compressed, cooled, and dried prior to storage in low-pressure holders, the compressed gas before cooling being passed through a tubular heat exchanger, through which, in the opposite direction is passing the compressed dried gas on its way to the expansion device. The holders may be sealed with oil, glycerin or other liquid instead of water. Alternatively the gas may be dried by reducing its pressure whilst it passes through a cooling device and before it reaches the high-pressure containers.—A. B. S.

Sulphur; Recovery of —— from material containing the same, especially spent gas-purifying material. Badische Anilin- und Soda-Fabr. G.P. 357,033, 25.3.19.

HOT inert gases, such as the products of combustion of producer gas, are led through a mass containing sulphur, *e.g.*, spent gas-purifying material, and the issuing stream of gas is cooled to a point above the melting point of sulphur, whereby liquid sulphur is deposited. A portion of the gas is subsequently withdrawn and the remainder is mixed with a fresh supply of hot gas and again passed through the material, or a portion of the gas may be circulated repeatedly through the mass before it is cooled.—L. A. C.

Sodium bicarbonate; Production of ——. Nitrogen Corp., Assees. of E. E. Arnold and P. St. Clair, jun. E.P. 159,895, 8.3.21. Conv., 11.3.20.

SEE U.S.P. 1,423,510 of 1922; J., 1922, 669 A.

Separating constituents of gaseous mixtures, Method of ——. [*Recovery of argon from air.*] G. Claude, Assr. to L'Air Liquide, Soc. Anon. pour l'Etude et l'Exploit. des Proc. G. Claude. U.S.P. 1,426,461, 22.8.22. Appl., 6.12.17.

See E.P. 114,817 of 1917; J., 1918, 416 A.

Sulphur; Manufacture of finely divided ——. A. Mittasch and F. Winkler, Assrs. to Badische Anilin- und Soda-Fabrik. U.S.P. 1,429,522, 19.9.22. Appl., 19.8.21.

See E.P. 177,103 of 1921; J., 1922, 373 A.

VIII.—GLASS; CERAMICS.

Patents.

Glass; Materials or receptacles for the handling of molten ——. Naaml. Vennoots. Philips' Gloeilampen Fabrieken. E.P. 172,610, 9.11.21. Conv., 4.12.20.

Surfaces which come into contact with molten glass after its removal from the furnace are constructed of chromium or of alloys of chromium or aluminium with iron, cobalt, or nickel, or other metals or alloys characterised by high melting points, by the absence of the evolution of gas when heated, and by the production of a firmly adhering coating of oxide or oxides insoluble in the molten glass. Thus an alloy consisting of 60% of iron and 40% of chromium may be employed.—J. S. G. T.

Enamelling processes. De Dietrich et Cie. E.P. 165,785, 22.6.21. Conv., 5.7.20.

Economy of fuel is obtained by causing the ignition of a current of hot air and purified producer gas as the mixture enters the enamelling kiln, combustion of the gases being completed in direct contact with the articles to be enamelled.—C. A. K.

Mineral product for use as an abrasive, polish, and the like. W. G. W. Sandison. E.P. 185,578, 16.7.21.

A mineral (serpentine) consisting of hydrated magnesium silicates and containing 3—5% of iron is crushed and calcined until partial fusion occurs. The cooled material is then crushed to the desired degree for use as an abrasive. [Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 2321 of 1883.]—C. A. K.

Kilns for burning bricks, tiles, terracotta and the like; Construction of ——. J. B. and A. H. Jones. E.P. 185,664, 18.10.21.

A group of intermittent kilns is connected by suitable flues and dampers, so that the hot gases from the bottom of any one kiln are conveyed through a common interconnecting flue to another kiln ready for burning. The gases enter the second kiln from a peripheral flue outside the kiln or under the line of fireboxes; vertical flues placed between the fireplaces then convey the gases to the upper part of the kiln chamber. Each kiln is provided with a direct flue to a separate chimney, so that an alternative method of firing is possible.—C. A. K.

Sheet glass; Method of and apparatus for drawing ——. W. J. Mellersh-Jackson. From Libbey Owens Sheet Glass Co. E.P. 185,921, 28.7.21.

Gas-tight seals between metals and vitreous materials. E.P. 185,952. *See* IIB.

IX.—BUILDING MATERIALS.

Cements of high strength. J. Hendrickx. Chim. et Ind., 1922, 8, 296—304.

In a study of factors influencing the quality of Portland cement, viz., chemico-physical composition, calcining and quenching, and fineness of grinding of the calcined product, the author recommends for general practice a standard chemical formula $xSiO_2,2{\cdot}5CaO+yAl_2O_3,3CaO+Fe_2O_3,3CaO$, the silica modulus lying between 2·5 and 1·8. Physical structure can be controlled, less empirically than heretofore, by a determination of "calcining capacity": 1 g. of raw mix, after partial calcining under standard conditions, should leave a residue of 6—7·5% after treatment with acid and alkali (Le Ciment, 1920). A spectrographical study of cements of high strength does not show that the presence of small amounts of rare elements (*e.g.*, beryllium) influences the strength as in the case of steels. Experiments on variations in the speed of calcining and of cooling, and a microscopical study of the resulting products, show that greater strength is obtained the larger the crystals in the clinker. Two kinds of crystals are observed, one with strong double refraction; the hydraulic properties of Portland cement are attributed, however, entirely to the non-birefringent kind. Soft aluminous cement was found to be a mixture of two crystalline components—aluminates and silicates in a vitreous base of iron—and not aluminates in iron silicate as hitherto supposed. Here the non-birefringent crystals are identical with the alite of Portland cement. A study of tensile strengths under varying "fineness moduli" (*i.e.*, sp. gr.÷wt. per litre of crushed cement) while again emphasising the importance of large crystals, shows that fine grinding of the clinker will correct faults in the less easily regulated processes of calcining and cooling. "Calcining capacity" can be improved in its turn, thus increasing the output of the kiln and quickening the speed of calcining.—J. B. P.

Wood; Impregnation of —— *with mercuric chloride.* R. Nowotny. Oesterr. Chem.-Zeit., 1922, 25, 102—104.

In Kyan's process for impregnating wood with mercuric chloride, the wood absorbs the salt more rapidly than the water, with a consequent fall in the concentration of the solution. The wood may be steeped in a ⅔% solution of mercuric chloride, and more of the salt may be added from time to time to maintain the solution at this strength, but equally good results may be attained by starting with a 0·7% solution without any further addition of the salt. Absorption both of solution and of mercuric chloride proceeds rapidly at first and later at a diminishing rate, but a maximum absorption is not attained even after a considerable period; the quantities absorbed, both of solution and of mercuric chloride, are parabolic functions of time. Data obtained during the treatment of pine and fir wood are tabulated. It is desirable in practice that all wood destined for use for the same purpose should be impregnated to the same extent, and thus it is essential to take into consideration not only the initial concentration of the solution and the time of treatment, but also the variations in rate of absorption by different species of wood. A series of experiments showing, *e.g.*, that fir and pine must be treated for 10 days and 7 days respectively for equal absorption.—L. A. C.

Patents.

Composition for hard tennis courts, skating rinks, paths, and the like; Method of production of ——. A. D. Thompson and H. A. Bird. E.P. 185,838, 10.6.21, and 2.3.22.

A mixture of sand, York stone or other stone chippings or cement, granulated cork, shredded rubber, "chromium oxide viride," and copper dust or filings.

Wooden poles and the like; Process for impregnating —— *with fluorides, and copper, zinc, and mercury salts.* H. Marten. G.P. 356,902, 14.10.20.

Wooden poles, such as telegraph poles, are treated with solutions of fluorides, or copper sulphate or zinc chloride, until the salts have penetrated nearly to the tops of the poles. The poles are then, in the same apparatus, treated at the base with mercuric chloride solution until it has penetrated through a length of about 2 m. The portion of the poles to be embedded in the earth is thereby impregnated with mercuric chloride, while the portion exposed to the air contains fluorides or copper or zinc salts as preservatives.—L. A. C.

Lime kilns, cement kilns, and the like; Furnace-drawing apparatus for ——. C. Candlot. U.S.P. 1,429,925, 26.9.22. Appl., 9.8.21.

See E.P. 150,994 of 1920; J., 1921, 697 A.

Drying apparatus [*for timber*]. E. C. R. Marks. From Natural Air Dryers, Inc. E.P. 186,207, 22.7.21.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Grey cast iron; Soft annealing of ——. E. Piwowarsky. Stahl u. Eisen, 1922, 42, 1481—1483.

A number of annealing experiments were carried out at various temperatures and for different periods of time on a pearlitic grey iron (carbon 3·18%, graphite 2·49%, silicon 2·95%, sulphur 0·068%, phosphorus 0·102%, manganese 0·63%) and on this material alloyed with 1% of nickel and 20% of steel respectively. Annealing below Ar1 did not produce decomposition of the pearlite in the case of the iron alloyed with 20% of steel and the rate of decomposition for the other two materials was not sufficient for practical purposes. In the temperature interval between Ar1 and Ac1 the softening is at a rate sufficiently high for practical purposes if the silicon content is high enough. Quick heating to a little above the Ac1 point with a final cooling through the Ar1 interval at a rate less than 1° to 2° per min. is the surest means of obtaining quick annealing.—T. H. Bu.

Grey cast iron; Determination of the critical temperature for annealing ——. E. Schüz. Stahl u. Eisen, 1922, 42, 1484—1488.

In pearlitic grey cast iron, the phosphide eutectic, unless segregated, has no practical influence on the hardness. The influence of graphite on the hardness has also been exaggerated, the size of the graphite flakes having very little effect. On annealing thick grey iron castings the separation of ferrite is frequently propagated from the edges to the centre. In experiments made to determine the temperature at which pearlitic grey iron is decomposed into ferrite and temper carbon, the critical range was found to be lower than is usually accepted. With an annealing period of 24 hrs. the decomposition of the carbide commences at 500° C. and is complete at 600° C.; for a 6-hrs. anneal the action commences at 550° C. and is complete at 650° C.; whilst with an annealing period of 3 hrs. the decomposition begins at 575° C. and is complete at 650° C. The bearing of the results obtained on the iron-carbon diagram is considered.—T. H. Bu.

Iron; Recrystallisation of technical ——. P. Oberhoffer and H. Jungbluth. Stahl u. Eisen, 1922, 42, 1513—1519.

The relation between the grain size, amount of deformation the metal has undergone, and subsequent temperature of annealing has been determined for four samples of technical iron containing up to 0·18% C, and the results are reproduced on space diagrams. For all annealing temperatures above 600° C. the maximum grain size is obtained after the metal has been subjected to compression sufficient to reduce its height 10%, and the individual grains are largest when such metal has been annealed at 800° C., an average grain size of 15,000—20,000μ^2 being then obtained compared with an original value of less than 1000μ^2. The presence of silicon and manganese in the metal tends to decrease the maximum grain size, whereas ageing increases it. No relation between recrystallisation and pearlite formation could be found. —A. R. P.

Iron; Effect of heat treatment on the hardness and microstructure of electrolytically deposited ——. N. B. Pilling. Trans. Amer. Electrochem. Soc., 1922, 35—43. [Advance copy.]

The effect of annealing electro-deposited iron was observed at intervals of 100° C. up to 950° C. The original hardness of the iron was unaffected by annealing up to 200° C. An increase in hardness of more than 70% occurred at 300° C., the maximum value being reached between 300° and 400° C. At this stage the hardness (45, scleroscope) was equivalent to that of a 1·2% carbon steel in the annealed condition. Annealing at temperatures above 400° C. produced progressive softening, interrupted by a slight hardening at 900° C., following the A3 transformation. The needle-like striations in normal electrolytically deposited iron coalesced into larger elongated grains at 600°—700° C. A considerable quantity of hydrogen was evolved during the annealing operations and was assumed to be due to an unstable compound of iron and hydrogen. Active evolution of hydrogen occurred at 90° C., but complete decomposition of the iron-hydrogen compound was not effected until the A3 transition point was exceeded.—C. A. K.

High-speed steel; Shrinkage and expansion of —— *due to heat treatment.* M. A. Grossmann. Chem. and Met. Eng., 1922, 27, 541—544.

When high-speed steel (0·65% C, 18·0% W, 4·0% Cr, 1·0% V) was heated, quenched, and drawn at varying temperatures there was a regular trend of the contractions and expansions (measured at room temperature) irrespective of the quenching temperature. Increasing values for contraction were observed when the steel was reheated to 1000° F. (540° C.), followed by an expansion when heated at 1000°—1100° F. (540°—590° C.), above which temperature contraction again set in. When the steel was drawn some change took place up to 1000° F. (540° C.), which decreased the hardness due to quenching from higher temperatures; the increasing hardness after annealing at above 1100° F. (590° C.) is attributed to the appearance of a new constituent. Microscopical examination supports the evidence for the existence of a new constituent. By correlating the evidence it is considered that a secondary martensite is formed when the steel is annealed at 590° C., probably from a secondary stable austenite. Martensite II is more stable than the primary martensite formed on cooling steel, and is decomposed only by subsequent heating at temperatures higher than 1100° F. (590° C.), which causes the final contraction of the steel and its return ultimately to the dimensions of the annealed condition.—C. A. K.

Copper; Electrolytic refining of ——. Separation of silver from argentiferous slimes. J. M. Fernández Ladreda. Anal. Fís. Quím., 1922, **20**, 199—206.

Argentiferous slime from the electrolytic refining of copper, containing sulphates of iron and copper, is roasted at such a temperature that the copper and iron sulphates are decomposed and the silver is converted into silver sulphate, which is separated by leaching. The recovery of silver may be made more complete by addition of potassium bisulphate, copper sulphate, and sulphuric acid. The roasting must be carried out in an oxidising atmosphere to avoid the formation of cuprous oxide.—G. W. R.

Zinc; Effect of single impurities on the electro-deposition of —— from sulphate solutions. J. T. Ellsworth. Trans. Amer. Electrochem. Soc., 1922, 187—202. [Advance copy.]

The effect of small quantities of each of the following metals as a single impurity in zinc sulphate cells was investigated: copper, manganese, cadmium, iron, cobalt, antimony, and calcium. Tests on pure zinc sulphate solutions showed that with sufficient zinc ions present, fairly high acidity, and not too low current density, an efficiency of 90—100% could be reasonably expected during the first 24 hrs. and of 80—90% for the next 24 hrs. Antimony, copper, and cobalt seriously reduce this efficiency, and the recommended maxima for these impurities are, 0·7 mg. per l., 10 mg. per l., and 12 mg. per l. respectively. Iron does not affect the efficiency if less than 50 mg. per l. is present, while cadmium actually improves it, but should not exceed 0·5 g. per l. or the deposit becomes rough and black. Manganese has no effect unless more than 1 g. per l. is present, when it causes pitting and eventually the formation of large holes. Lime is objectionable only when the solution is nearly saturated with calcium sulphate, which then may crystallise on the cathode and contaminate the deposit.—A. R. P.

Zinc; Electroplated —— and the diffusion of electro-deposits into zinc. W. G. Traub. Trans. Amer. Electrochem. Soc., 1922, 13—17. [Advance copy.]

When copper, brass, gold, or silver coatings are deposited on zinc the coatings disappear after a few months. Experiments show that this is due to diffusion of the surface metal into the zinc and may be prevented by first coating the zinc with nickel which does not diffuse into it.—A. R. P.

Aluminium; Simple crucible furnace for melting ——. A. G. Lobley. Trans. Amer. Electrochem. Soc., 1922, 169—172. [Advance copy.]

A furnace suitable for melting and keeping molten aluminium for the manufacture of small die castings consists of a nichrome ribbon resistor wound in a helix and supported on thin firebrick shelves around, but not touching, a fireclay crucible. The crucible is removable for renewals without disturbing the resistor, and the whole is insulated in a brickwork container with kieselguhr. The capacity of a crucible is 35—40 lb. of aluminium, which is melted by a current of 20 amps. at 200 volts, the energy consumed being 0·78 kw.-hr. per lb. of metal. This furnace showed a saving of 15% in running expenses compared with a gas-fired crucible furnace, and the metal losses are considerably reduced.—A. R. P.

Nickel deposition; Application of the contractometer to the study of ——. E. A. Vuilleumier. Trans. Amer. Electrochem. Soc., 1922, 159—168. [Advance copy.]

The primary cause of the peeling of electrodeposited nickel seems to be a tendency of the deposited metal to undergo a contraction which causes the deposit to bend towards the anode. This may be measured by depositing the nickel on a thin platinum sheet cathode and ascertaining by means of the contractometer (Kohlschütter and Vuilleumier, Z. Elektrochem., 1918, 24, 300) the amount of bending. While an increase in the p_H of the solution causes at first a more rapid bending, still greater acidity reduces it at the same time as the cathode efficiency. Iron salts increase the bending 50%, but a trace of zinc causes a marked decrease and the deposit becomes more velvety. At times there are delays and spurts in the contraction, especially when very little hydrogen is evolved at the cathode; when much hydrogen is evolved the nickel expands, possibly owing to the formation of nickel-hydrogen analogous to palladium-hydrogen.—A. R. P.

[*Nickel;*] *Effect of impurities in nickel salts used for electrodeposition* [*of* ——]. M. R. Thompson and C. T. Thomas. Trans. Amer. Electrochem. Soc., 1922, 123—138. [Advance copy.]

Small amounts of zinc in nickel sulphate and nickel ammonium sulphate used for making up plating baths tend to cause the deposits to have bright edges and smooth surfaces, while larger amounts cause the formation of bright spots and tend to increase pitting, the effect in each case becoming more marked the longer the deposition is continued. The effect of zinc may be counteracted to a great extent by neutralising the solution with nickel carbonate to p_H 6·7, filtering, and re-acidifying to p_H 5·8, the electrolysis being then conducted at a high current density for some hours. Copper, even in small amounts, causes the deposits to become rough and somewhat burred, and the effect is more marked the longer the deposition is continued. The solution may be purified in the same manner as in the case of zinc. Iron does not seem to have a deleterious effect on the deposits even when they contain as much as 7% Fe. On the contrary, the presence of iron in deposited nickel makes the metal whiter, more finely crystalline and harder. The authors recommend that the impurities in nickel salts used for electroplating should not exceed 0·05% Zn, 0·02% Cu, 0·1% Fe, and 0·1% of free sulphuric acid.—A. R. P.

Current distribution and cathodic electrodeposition upon surface cavities of bodies in electrolytic baths. K. Arndt and O. Clemens. Chem.-Zeit., 1922, 46, 925—926.

The distribution of current along numerous paths from anode to cathode in an electrolytic bath is of consequence in electrodeposition upon uneven surfaces, and is especially marked in the case of electrodeposition from solutions of gold and potassium cyanides, the deposition of gold upon the side of the cathode remote from the anode being almost equal to that upon the nearer side. The authors have investigated the distribution of the deposited metal upon the respective plates of a composite cathode consisting of two plates electrically connected and disposed at different distances from a single anode, more especially in the case of the electrodeposition of nickel. The proportional electrodeposition upon more remote parts of the cathode increases as the concentration of metallic ions in the electrolyte decreases, the resistance of the bath being unaltered. A similar increase accompanies an increase of specific conductivity of the electrolyte, the total content of electrolyte being maintained constant. The effect is pronounced in cyanide baths, as the ionic concentration of the metal is small owing to the formation of complex anions.—J. S. G. T.

Nickel alloys which maintain their rigidity over a wide range of temperature. P. Chevenard. Comptes rend., 1922, 175, 486—489. (*Cf.* J., 1920, 26 A.)

Alloys of nickel were studied from the standpoint of their rigidity at temperatures ranging up to 850° C., and a diagram is given in which their behaviour under test conditions is shown in comparison with that of electrolytic iron and of chrome-nickel steel. An addition of 15% of chromium to nickel raises by 150° the upper temperature limit of the range within which the metal remains rigid, but raising the chromium content to 22·6% gives only a slight further increase. The former proportion is found to be more advantageous, as difficulties of manufacture and forging increase considerably with chromium content. The best results were obtained with nickel containing 9% of chromium and 5·8% of tungsten; in this alloy the nickel may be replaced by ferro-nickel of 60% nickel content without detriment to the rigidity, and the manufacture of the alloy is thus facilitated and the cost is decreased. The method of determining rigidity was based on measurements of a wire from which a weight was suspended, the wire being placed in a furnace of constant temperature. Photographic records of the stretching of the wire were made and the increase in length was plotted as a function of time. The quaternary alloys of iron, nickel, chromium, and tungsten are tough, highly resistant to chemical action, and considerably more rigid at high temperatures than the usual types of steel.
—H. J. E.

Patents.

[*Iron and steel; Composition for use in the*] *case hardening, hardening, and tempering* [*of* ——]. E. J. Dickins. E.P. 185,564, 6.7.21.

A composition for application to portions of iron and steel articles which it is desired should remain soft when the article is subjected to a hardening or case-hardening process, consists of a mixture containing 56% of kaolin, 19% of barium sulphate, 19% of powdered silica, and 6% of a solution of sodium silicate of sp. gr. 1·2.—A. R. P.

Iron and steel wire; Solution for use in drawing ——. O. Vogel. G.P. 299,031, 21.6.16.

A slightly acid solution of copper sulphate is mixed with one or more chlorides, *e.g.*, sodium chloride and ferric chloride. The iron or steel wire is coated with copper by immersion in this solution, and after drawing, the copper coating is removed by treatment with an ammoniacal solution of copper sulphate. By using the mixture of salts copper separates more easily than from copper sulphate alone, and the copper adheres better to the wire, so that a thinner coating can be used than hitherto.—T. H. Bu.

Iron and steel wires; Solution for use in wet drawing of ——, *also for pickling.* O. Vogel. G.P. 299,032, 31.5.16.

The medium consists of two or more suitable chlorides, including preferably ferric chloride, with the addition of sufficient ammonia to produce a certain quantity of colloidal ferric hydroxide. By the addition of ammonia the solution adheres better to the wire and its lubricating action is increased. The composition of the solution remains unchanged and the wire keeps clean till the end. When the solution is to be used for pickling the ammonia is omitted.—T. H. Bu.

Ferro-tungsten; Method of purifying tin-bearing ——. F. M. Becket. U.S.P. 1,429,272, 19.9.22. Appl., 26.5.20.

The comminuted alloy is treated with an acid solvent for tin.—C. I.

Calorising metals; Furnace apparatus more particularly adapted for ——. F. H. Rogers. From Calorizing Corp. of America. E.P. 184,839, 19.4.21.

In apparatus specially adapted for calorising metals (by heating with aluminium powder or the like in an atmosphere of non-oxidising gas), gas is delivered to a rotary retort through a pipe consisting of a portion rotating with the retort and a stationary portion connected with the former by means of a gas-tight joint. The non-rotating part is pivoted to the upper end of a vertical support so as to permit of slight eccentric motion of the retort. Close connexion between the non-rotary and rotary parts of the delivery pipe is maintained by means of a coiled spring. The closing plates on the retort are arranged so as not to be subjected to any weight, this being carried by flanges on the retort resting on bearing rollers.—C. A. K.

Metallurgical furnace. C. C. Roller. U.S.P. 1,429,777, 19.9.22 Appl., 30.10.20.

The down flue of a metallurgical furnace communicates with a tunnel in which are rails capable of being raised or lowered and which support a car having a detachable body. By raising or lowering the rails, the car may be moved into and out of engagement with the flue, making a joint therewith.
—A. J. H.

Furnace; Ore-treating ——. C. C. Grimes. U.S.P. 1,430,445, 26.9.22. Appl., 26.3.19.

An inclined retort is heated by a vertical flue communicating with the bottom of the retort chamber. Within the upper part of the retort pipe is a perforated fume-collecting pipe.—C. I.

Alloys; Readily fusible ——. A. de W. Mulligan. E.P. 185,012, 23.8.21.

Fusible alloys possessing physical properties which render them suitable for temperature indicators for bearings contain Sb 0·8—2·5%, Sn 12—29·6%, Pb 12—61%, Cd 6·6—18%, Bi 3—50%. The ratio of the content of tin to that of antimony is 12 to 1.
—C. A. K.

Ores containing copper silicate; Treatment of ——. H. L. Sulman, T. J. Taplin, jun., W. G. Perkins, and H. F. K. Picard. E.P. 185,242, 9.6., 16.7., 6.8., and 9.12.21.

Ores containing copper silicate (chrysocolla) and copper carbonate (malachite and azurite) are heated, after crushing, at 150°—400° C. and treated with an ammoniacal solvent. The heating process reduces the copper without any fritting and the reduced material is obtained as a porous mass. The reduced material may be re-oxidised before leaching.—C. A. K.

Annealing and/or other heat treatment of metals. W. and C. A. Barron. E.P. 185,277, 8.7.21.

An annealing pot is provided with a double lid forming a chamber through which a stream of non-oxidising gas is passed during the heating and cooling periods.—C. A. K.

Tungsten carbides; Process for the manufacture of —— *without free carbon for use as tools and implements of all kinds.* P. C. Rushen. From Akt.-Ges. B. Felder-Clement. E.P. 185,313, 15.8.21.

Tungsten carbides are made best at a temperature higher than the temperature of formation of the carbides, but this results in the separation of graphite during cooling (G.P. 289,066 and 286,184; J., 1916, 423; 1915, 1250). The free carbon is removed and a coarse crystalline structure prevented by the addition of molybdenum, molybdic acid, molybdenum oxide or carbide, to the fused crude tungsten carbide. The molybdenum compound volatilises completely and enables free carbon to be removed with it, so that it is not necessary to oxidise all the free carbon to its oxides. 7—8% of molybdenum is used for effective decarburisation. The fused tungsten carbide is suitable for casting, particularly in moulds with the use of centrifugal force (E.P. 157,756).—C. A. K.

Tin; Process for the electrolytic refining of ——. W. P. Thompson. From W. J. Aikens. E.P. 185,808, 31.5.21.

A BATH, suitable for the electrolytic refining of crude tin containing lead, is formed by dissolving tin in a 15·5% solution of hydrofluosilicic acid until 4·5% of the weight of solution in tin is dissolved, and adding to the solution thus obtained 0·1 to 0·3% of phosphoric acid to precipitate lead, and 0·1% of cresylic acid to prevent the formation of crystalline or hair growths on the cathode. Addition of 0·05—0·01% of glue to the bath renders the deposit harder and more compact. Crude tin is used as anode and pure tin sheets as cathodes.—A. R. P.

Tungsten or molybdenum; Electrolytic treatment of metalliferous materials containing ——. R. E. Pearson, E. N. Craig, and Durelco, Ltd. E.P. 185,842, 11.6.21.

TUNGSTEN or molybdenum ores or waste products are ground and mixed to a paste with sulphuric acid, and the mixture is placed on a lead plate which forms the anode of an electrolytic cell containing dilute sulphuric acid. On passing a current through the cell the basic impurities, *e.g.*, iron, manganese, calcium or sodium oxides, in the material on the anode pass into solution, leaving a residue of tungsten or molybdenum oxides. Alternatively the anode may consist of nickel or a nickel alloy, and the electrolyte of caustic soda, whereby soluble sodium tungstate or molybdate is formed and the foreign metals are left as anode slime. The process is applicable to the utilisation of scrap molybdenum or tungsten metal.—A. R. P.

Copper; Process for colouring ——. F. Laist, F. F. Frick, E. Klepetko, and L. P. Davidson, Assrs. to Anaconda Copper Mining Co. U.S.P. 1,428,170, 5.9.22. Appl., 29.11.21.

COPPER or bodies containing copper are subjected to the action of a concentrated solution of a copper salt.—C. A. K.

Zinc from complex ores; Process for recovering ——. J. T. Ellsworth. U.S.P. 1,429,330, 19.9.22. Appl., 12.7.21.

IN a cyclic process for extraction of zinc by a solvent and deposition of the metal by electrolysis, the solution prior to electrolysis is concentrated, separated from the crystals formed, and diluted to such an extent that the concentration of the soluble salts therein will be insufficient to produce supersaturation at any subsequent stage in the cycle.—B. M. V.

Flotation process; Differential ——. B. Stevens. U.S.P. 1,429,544, 19.9.22. Appl., 8.3.20.

THE ore pulp is treated with a selective flotation agent consisting of a substance which dissolves one of the metals that is capable of being floated and which is saturated with that metal.—A. R. P.

Ore concentration, more especially for purifying graphite; [Flotation] process of ——. Elektro-Osmose A.-G. (Graf Schwerin Ges.). G.P. 356,503, 22.7.19.

CRUSHED ores are subjected to a flotation process in a medium composed of a molten substance of greater density than water, and from which gases are evolved, at or above its melting point, owing to decomposition or dehydration. The ores may, if desired, be mixed with oil or be subjected to a preliminary oil-flotation purification process. Gases or steam may be blown into the molten material.
—J. S. G. T.

Ores; Concentration of —— by flotation. Elektro-Osmose A.-G. (Graf Schwerin Ges.). G.P. 356,815, 6.2.19.

ORE pulp is agitated by means of air in the lower part of a vessel, the upper part of which is covered, partly or wholly, with a sieve through which the gangue particles are dispersed, while the froth is withdrawn over an open rim. The level of the liquor in the vessel is maintained automatically so that contamination of the froth with gangue particles does not occur.—A. J. H.

Lead and zinc; Extraction of ——. W. G. Waring, Assr. to G. Battella. U.S.P. 1,430,270, 26.9.22. Appl., 17.8.21.

ORES containing lead and zinc are extracted with a hot ammonium sulphate solution to remove the zinc, and the residue containing the lead is treated with an ammonium carbonate solution containing ammonia equivalent to the sulphur trioxide present in the residues. Lead carbonates are formed, and an ammonium sulphate solution containing zinc. The ammonium sulphate solution can be used again for the extraction of the zinc.—H. C. R.

Pure nickel; Process for the preparation of —— from impure nickel sulphate. E. Günther. G.P. 356,531, 10.4.21.

A SOLUTION of crude nickel sulphate is treated with sodium chloride sufficient to convert all the metals present into chlorides, and the resulting sodium sulphate is crystallised out by strongly cooling the solution. The chloride liquor so obtained is treated with hydrogen sulphide to remove the metals of group 2, and the filtrate is oxidised and treated with limestone to precipitate iron and manganese. The remaining sulphuric acid is precipitated with barium chloride and from the clear liquor nickel hydroxide is precipitated and reduced to metal, which is pure except for a trace of cobalt.
—A. R. P.

Metals; Treatment of ——. Th. Goldschmidt A.-G., und L. Schertel. G.P. 356,532, 16.2.17.

MATERIALS containing volatile metals or metals yielding volatile oxides are subjected while in the molten condition to a blast of burning gas. Oxidation of the metals occurs, the metallic oxides are volatilised and are separated, and subsequently converted into metal.—A. J. H.

Ores; Process for treating ——. W. J. Mellersh-Jackson. From Soc. Metalurgica Chilena "Cuprum." E.P. 184,501, 10.2.21.

XI.—ELECTRO-CHEMISTRY.

Anode carbons; Stability of ——. K. Arndt and W. Fehse. Z. Elektrochem., 1922, 28, 376—381.

A method of estimating the graphite content of a specimen of carbon consists in determining the electrical resistance of the material, powdered and carefully graded, under a definite mechanical pressure, and comparing the result with a standard curve obtained from carbons of known graphite content. The chemical resistance of the carbons was determined by using them as anodes in the electrolysis of a solution of sodium chloride and chromate, and determining the loss in weight. The resistance increases generally with the graphite content, but the highest resistance was shown by a carbon containing 75% of graphite. Microscopical examination showed that the structure of the carbon must be fairly coarse and free from cavities, and that this condition is best fulfilled in specimens graphitised up to about 75%.—E. H. R.

Resistor carbons; Resistivities of some granular ——. C. E. Williams and G. R. Shuck. Trans. Amer. Electrochem. Soc., 1922, 109—121. [Advance copy.]

The electrical resistances of granular varieties of graphite, carbon, coal-tar residue, coke, coal, and charcoal have been determined at various temperatures up to 1600° C. The samples were heated for several hours at 1000° C. prior to being tested. The difference of resistivities of the various samples was not large at 1000°—1200° C. The temperature-coefficient of resistance was in all cases negative up to 1000°—1200° C., approaching zero at that temperature, and becoming positive at still higher temperatures. This change was more pronounced in graphite than in the other forms of carbon. The resistivity increased as the size of granule decreased. High resistivity accompanied the presence of volatile matter. Ash contained in the granules increased the contact resistivity and temperature-coefficient only slightly, while the effect of extraneous ash or foreign matter of high resistivity was very marked in this connexion.—J. S. G. T.

Alloys [used as heating elements]; Electrical properties of —— at high temperatures. M. A. Hunter and A. Jones. Trans. Amer. Electrochem. Soc., 1922, 139—158. [Advance copy.]

Materials used as heating elements are divided into two classes. The first, including nickel, copper-nickel and iron-nickel alloys, have high specific resistances at the operating temperature and are suitable for use up to 500° C. The second, including nickel-chromium, nickel-iron-chromium, and iron-chromium alloys, in addition withstand oxidation, and are more or less suitable for use up to 1100° C. Tables are given of the comparative values of the specific resistances of the various alloys at intervals of 100° C. for the range 20° C.—1000° C., and of the respective values of the specific resistances in ohms/mil foot at room temperature. The life of a nickel-chromium alloy is related to its chromium content. For temperatures in excess of 1000° C. the chromium content of the wire should be as high as possible. An alloy containing 20% Cr is recommended as possessing the best manufacturing and operating characteristics. The resistance of a bright wire increases on oxidation by 3—4·5%.
—J. S. G. T.

Insulating compounds; Arc action on some liquid ——. C. J. Rodman. Trans. Amer. Electrochem. Soc., 1922, 45—56. [Advance copy.]

Results are given of tests of the electrical disruption of insulating liquids of low viscosity and high fire and flash points, between ball electrodes, at and below the liquid surface, the maximum difference of potential employed being 100,000 volts. Among the liquids tested were gasoline (68°), various transformer oils, benzol, monochlorobenzol, orthodichlorobenzol, dichloromethane, chloroform, and carbon tetrachloride, and mixtures of halogen compounds with mineral oils. The products obtained on disruption were: finely divided, non-conducting amorphous carbon, saturated and unsaturated hydrocarbons lower in the series, hydrogen, unsaturated hydrocarbons, carbon monoxide, methane, and ethane, and hydrochloric acid in the case of chlorinated compounds. Increase of molecular weight in the paraffin series was accompanied by a decrease of gas evolved per kilowatt-sec. of arc rupture. A similar decrease likewise accompanied increased halogenation of the oils. The average yield of gas from a mineral oil was about 97 c.c., and from a highly chlorinated oil was as low as 4·2 c.c. per kilowatt-sec., the gas in the latter case being non-explosive when mixed with air in any proportion. Liquid dielectrics are apparently broken down by a temperature-pressure effect of very short duration rather than by the effect of high frequency alone.—J. S. G. T.

Corona effect; Chemical reactions induced by the —— in circuits traversed by continuous currents. C. Montemartini. Gazz. Chim. Ital., 1922, 52, II., 96—97.

Since the corona effect is due to the emission of electrons, the gas surrounding the conductor producing the effect should be ionised, and the effect should be capable of inducing those chemical reactions which are caused by discharges in rarefied gases or by the dark discharge. As far as a number of these reactions (formation of ozone, decomposition of carbon dioxide, formation of ammonia from nitrogen and hydrogen, etc.) are concerned, this is found to be the case. Patents.

Galvanic cell. A. Heil. E.P. 173,515, 28.12.21.

The carbon pole of a galvanic cell is surrounded by a depolariser consisting of manganese dioxide or hydrated manganese dioxide mixed with carbon or graphite. The negative pole is of copper gauze, copper-plated lead, or copper-plated carbon, surrounding the depolariser and immersed in the electrolyte, which consists of dilute sulphuric acid together with copper sulphate and manganese sulphate. The whole is contained within an airtight lead casing. The cell is free from "gassing" and can be used as an accumulator.—J. S. G. T.

Galvanic cell with electrodes composed of manganese dioxide and acetylene soot. P. Burger. G.P. 357,090, 17.6.21.

About 5—20% of graphite is mixed with the soot incorporated in the electrodes. The mixture can be pressed into solid blocks sufficiently porous to soak up electrolyte, and the graphite confers a greater conductivity upon electrodes made from the mixture.—J. S. G. T.

Oxyhydrogen gas cell, employing fused alkali as electrolyte. E. Baur. G.P. 357,290, 20.2.21.

Bell-shaped metal vessels are used as electrodes, and are closed below by a mass of the same metal of large superficial area, in the form of a brush or wire net. The gas flows over this brush or net into the electrolyte. Gas leaking from the bell is delivered to a second bell surrounding the first, and is brought into heat-exchanging relation with a further supply of gas.—J. S. G. T.

Electric accumulators [*; Desulphating* ——]. W. O. Garbutt. E.P. 185,797, 11.5.21.

Sulphated lead electrodes are desulphated, after removal of sulphuric acid by passing a current of the customary density and voltage between them when immersed in a solution of an alkali hydroxide or peroxide of sp. gr. 1·100 or above, *e.g.*, a 10% solution of sodium hydroxide or peroxide.

—J. S. G. T.

Electrodes for arc welding and metal cutting and process for making the same. W. H. Boorne. E.P. 185,580, 19.7.21.

The electrode consists of a metal rod or core wound transversely with a carbonaceous fibre saturated with a solution of sodium borate and covered by means of an extrusion machine with a coating of a mixture of magnesite, aluminium, and sodium silicate while the fibre is wet. The coating may include graphite (not less than 98% of carbon) and crocidolite asbestos or amosite, with or without granulated magnesium.—T. H. Bu.

[*Iron*] *welding rods or electrodes and soldering sticks* [*; Composition for coating* ——]. E. H. Jones, and Alloy Welding Processes, Ltd. E.P. 185,813, 3.6.21.

A suitable proportion of "ferro-carbon alloy" containing 50% C and 50% Fe, or of "silicon-carbon" alloy (60% Si, 35% C, and 1·5% Fe), or of both, is added to the paste with which the welding rod is coated, so that the weld metal has sufficient carbon and/or silicon to give it the characteristics of cast-iron.—A. R. P.

Electric furnace. M. S. Clawson. U.S.P. 1,428,489, 19.9.22. Appl., 13.7.20.

An electric furnace comprises a main supporting member carrying a central member, and side members movable towards or from the central member and mounted on pivots. Resistance members, adapted to hold the material to be treated, are engaged between rotary heads mounted in the central and side members respectively.—J. S. G. T.

Electric conductors; Method of making [*aluminium*] ——. J. Lind. U.S.P. 1,429,441, 19.9.22. Appl., 26.4.21.

Aluminium conductors are insulated by heating and then quenching in an aqueous solution of soda.

XII.—FATS; OILS; WAXES.

Copra cake; Extraction of ——. A. P. West and J. M. Feliciano. Philippine J. Sci., 1922, 20, 509—517.

Copra cake was extracted with different solvents for various intervals of time in a Soxhlet apparatus. Ether, carbon tetrachloride, and benzene gave approximately the same percentage extraction. Chloroform, acetone, and petroleum ether dissolve not only the oil but also small quantities of non-fatty substances, while ethyl and methyl alcohols dissolve a considerable quantity of the latter. By extracting copra cake with carbon tetrachloride and afterwards extracting the oil-free cake with methyl alcohol the non-fatty material was obtained. It had a high acid and saponification value and contained a small percentage of nitrogen, which is possibly mainly in the form of amino-acids.

—H. C. R.

Fatty oils; Polymerisation of ——. J. Marcusson. Z. angew. Chem., 1922, 35, 543—544. (*Cf.* J., 1920, 755 A.)

The action of light on tung oil in the absence of air causes the oil to change into a solid the melting point of which varies with the nature and intensity of the illumination. The mass can be separated by treatment with acetone into a soluble fraction, consisting mainly of unchanged oil, and an insoluble fraction, which can be purified by recrystallisation from hot acetone, and consists of β-elæostearin (m.p. 61° C.). A small quantity of an infusible substance which is insoluble in hot acetone and in all usual fat-solvents remains behind. The formation of β-elæostearin by the action of light on α-elæostearin is a case of stereoisomeric rearrangement from the cis to the trans form. If the glyceride is exposed to the air or illuminated in a sealed glass tube polymerisation takes place, with the formation of the product insoluble in fat-solvents mentioned above. An acid can be prepared from the polymerised substance having an iodine value only one fourth that of elæostearic acid and a molecular weight twice as great. The formation of β-elæostearin causes the film of dried tung oil to be lacking in durability. This may be overcome by heating the oil to a high temperature before using it as an ingredient of paints and varnishes, as by this means it is converted into polymerised products which no longer give β-elæostearin on exposure to light, and a uniform and elastic film is obtained. The films formed by the drying of fatty oils contain unchanged oil, free fatty acids and oxy acids, and neutral polymerisation and oxidation products both in the sol and gel form.—H. C. R.

Oil-bearing materials, such as nuts, seeds and copra; Preservation and preparation for transportation of —— *[by compression in bulk]. Preservation and preparation for transportation of cotton seed.* A. W. MacIlwaine. E.P. 186,133 and 186,277, 17.6.21.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Varnishes; Changes in the electrical conductivity of [insulating] —— *during drying.* H. C. P. Weber. Trans. Amer. Electrochem. Soc., 1922, 89—96. [Advance copy.]

CERTAIN varnishes used for insulating purposes decompose during drying owing to oxidation, with the formation of acidic substances which are slightly volatile and of low electrical resistance. These may accumulate in certain parts of the insulation and cause an electrical breakdown. If they are allowed to volatilise by heating the material during drying, the resistance increases appreciably and the resulting insulation is satisfactory.—A. R. P.

Pine oil [" liquid resin," " polyterpene," " sulphate resin "]. H. Sandqvist. Z. angew. Chem., 1922, 35, 531—533.

THE oil is obtained as a by-product in the manufacture of wood pulp by the sulphate process from pine wood. From pure pine wood 45 kg. of oil is obtained per 1000 kg. of sulphate-cellulose. It is of use in the manufacture of detergents and for this purpose is purified by boiling with very dilute sulphuric acid, drying, and distilling under slightly reduced pressure at 260° C. with steam superheated to 360° C. About 75% distils over and 16% of pitch remains behind and can be used as a substitute for montan wax. The analysis of various samples taken from Swedish factories gave the following results. Crude oil: Viscosity (18° C., water=1) 717—8,000,000; sp. gr. at 15°/4° C., 0·977—1·026; water, 0·69—7·2%; ash, 0·07—4·62%, acid value, 107—160; insoluble in ether, <0·1—4·2%. Refined oil: Viscosity, 334—4000; sp. gr. at 15°/4° C., 0·967—1·001; acid value, 146—158·5; " indifferent matter," 12—19%; resin acids, 34—53%, of acid value 166·5—176; fatty acids, 29—51%, of acid value 189—193. The " indifferent matter " is not quite neutral and contains a substance of m.p. 136°—137° C., similar to phytosterol. The resin acids have sp. gr. 1·104 and are coloured dark brown. They are liquid at 130° C. The fatty acids have a mean sp. gr. 0·968. The liquid portion gave some stearic acid on hydrogenation. The technical application of pine oil depends largely on the possibility of separating the resinous and fatty acids.—H. C. R.

d-Pimaric acid of m.p. 212° C.; Preparation of ——. E. Knecht and E. Hibbert. J. Soc. Dyers and Col., 1922, 38, 221—222.

l-PIMARIC acid, of m.p. 161° C., $\alpha_D = -80°$, when exposed to the air for prolonged periods, or when subjected to alkaline oxidation is partially converted into the *d*-pimaric acid, $C_{20}H_{30}O_2$ of m.p. 212° C., $\alpha_D = +62·5°$, described by Laurent. Vesterberg and others. The reaction may conveniently be carried out by allowing a dilute solution of the sodium salt to stand overnight with sodium hypochlorite solution. The crystalline precipitate is filtered off, dissolved in boiling water, and decomposed with sulphuric acid. By recrystallising the liberated acid from alcohol, it is obtained in a pure condition in about 10% yield.—G. F. M.

Polymerisation of fatty oils. Marcusson. *See* XII.

PATENTS.

Friction facing and process of making same. L. Kirschbraun. E.P. 185,809, 1.6.21.

FRICTION facings are produced from a mixture of an incombustible fibrous pulp and a phenol resin, which is saturated with a binder and baked at a suitable temperature for producing the necessary strength and hardness. For example, asbestos pulp is mixed with about 5% of a comminuted soluble phenol resin and is then formed into sheets. Friction facings are cut from these and are calendered and sized in the usual way, afterwards saturated with bitumen of low melting point (100° F. or less) and then baked at 400°—500° F. (204°—260° C.) for about 24 hrs. The product has a tensile strength greater than 2000 lb. per sq. in. and a Brinell hardness greater than 15. The hardness is dependent on the phenol resin used.
—A. J. H.

Floor coverings and process of making same. L. Kirschbraun. E.P. 185,816, 6.6.21. (*Cf.* U.S.P. 1,302,810 of 1919; J., 1919, 494 A.)

FLOOR covering is made by passing a mixture of fibrous stock and a non-adhesive emulsified matrix over the inner cylinders of a multi-cylinder paper machine, simultaneously forming a felted ply of fibrous stock on an outer cylinder of the machine, then drying and coalescing the pitch binding material in the inner plies; the pitch binder forms an ingredient of the matrix, which also contains water, clay, sodium silicate, and aluminium sulphate. The outer top ply is substantially devoid of the pitchy medium and is coated with a drying oil of a different colour, providing a surface on which a design may be printed.—D. F. T.

Coating materials and methods of forming the same. British Thomson-Houston Co. From General Electric Co. E.P. 185,910, 18.7.21.

FOR the production of a comparatively permanent coating resistant to ordinary abrasion, high temperature, water, and weak acid, *e.g.*, for lamp shades and reflectors, kaolin or similar material is peptised by means of sodium hydroxide, an alkali silicate being then added as a binding agent together with any desired opacifying or colouring ingredients. The mixture is applied to the surface and is then treated with a fixing solution containing, for example, zinc chloride and aluminium sulphate, which reacts with the alkali silicate and prevents subsequent chemical action between this and atmospheric carbon dioxide.—D. F. T.

Coating composition and process of making the same. M. I. Strauss. U.S.P. 1,386,380, 2.8.21. Appl., 18.5.17.

Shellac is dissolved in caustic soda, the solution filtered, acidified with sulphuric acid, and the resulting precipitate washed, dried, and dissolved in alcohol, to yield a coating composition which, after drying, is impervious to, and unaffected by, gasoline and the like. Solid pigments, such as Venetian red or the like, may be added to the composition.

Condensation product of phenol and formaldehyde and method of making same. Phenolic condensation product and method of making same. W. Achtmeyer. U.S.P. (A) 1,429,265 and (B) 1,429,267, 19.9.22. Appl., 10.3.21.

(A) 100 pts. of phenol is condensed with 100 pts. of 40% formaldehyde solution in 30—40 pts. of hot water containing 3—5 pts. of sodium tungstate and 9—12 pts. of sodium phosphate in solution, and the resinous product is separated from the watery layer. (B) A phenolic substance is condensed with methylenediphenyldiamine.—A. R. P.

Japanese lacquer; Process of drying ——. Y. Shibata and Y. Nishizawa. U.S.P. 1,429,542, 19.9.22. Appl., 29.3.20.

A Japanese lacquer preparation containing 5—30% of a complex salt of metals and ammonium is claimed.—A. R. P.

Titanium complex [pigment] and method of producing same. H. H. Buckman. U.S.P. 1,429,841, 19.9.22. Appl., 20.12.20.

Fine white titanium pigments are obtained by heating under pressure with sulphuric acid and water, finely divided ilmenite and barium sulphate; after the addition of more water and re-heating, the solid product is dried and calcined.—D. F. T.

Plastic product. W. O. Snelling. U.S.P. 1,430,036, 26.9.22. Appl., 20.10.20.

A rosin ester is applied as a substitute for chicle. —D. F. T.

Zinc-lead fume; Treatment of ——. W. G. Waring, Assr. to W. G. Battelle. U.S.P. 1,430,271, 26.9.22. Appl., 17.8.21.

Zinc-lead fume intended for use as a pigment and containing sulphur is roasted at a low temperature to remove volatile impurities and to convert the cadmium into the soluble sulphate, which can be removed by leaching with water.—H. C. R.

Painter's size; Process for the preparation of ——. F. Sichel, Kommanditges., and E. Stern. G.P. (A) 349,280, 7.11.20, and (B) 353,568, 29.12.20.

(A) The size is made by digesting a mixture of starch with wholly or partly saponified fats, resins, or waxes, with an alkaline-earth hydroxide and a salt of an alkali metal which reacts to form alkali hydroxide. The product is dried or concentrated. (B) Part of this prepared product is added to further batches of raw material, and the mixture is subjected to the above treatment.—A. R. P.

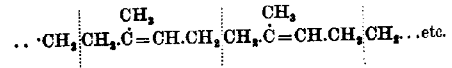
Plastic compositions; Production of —— from solid or semi-solid acid tars or the like. Plauson's Forschungsinst. G.m.b.H. G.P. 354,539, 6.12.19.

Acid tars or the like are treated at 80°—160° C., under atmospheric or increased pressure, with aldehydes in the presence or absence of phenols and/or condensation accelerators, such as sulphuric or hydrochloric acid, or starch. The products are either treated with organic solvents to extract constituents suitable for use in the manufacture of lacquers, or are used as plastic compositions. In the manufacture of the latter, sawdust is either added to the acid tar or mixed with the condensation product, or sawdust may be impregnated with extracts of the condensation product, and subsequently mixed with the insoluble residue remaining after extraction.—L. A. C.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Caoutchouc; Hydrogenation of —— and its constitution. H. Staudinger and J. Fritschi. Helv. Chim. Acta, 1922, 5, 785—806.

Purified plantation rubber was completely hydrogenised by treatment with hydrogen in presence of platinum at 270° C. and about 100 atm. With a nickel catalyst complete hydrogenation could not be obtained under these and even more severe conditions. The hydrogenated rubber has the composition $(C_5H_{10})_n$ and behaves towards bromine as a saturated compound. It forms a colourless amorphous mass, without the elastic properties of rubber but retaining its colloidal properties; it forms colloidal solutions in benzene, ether, and chloroform, but is insoluble in alcohol and acetone. It is attacked by bromine in sunlight, forming a brominated compound resembling rubber. The hydro-caoutchouc must be regarded as a high-molecular paraffin hydrocarbon with so large a molecule that C_nH_{2n+2} is practically equivalent to C_nH_{2n}. It is unattacked by vulcanising agents. This supports the view that the vulcanisation of rubber is a purely chemical process due to combination of the vulcanising substance with the rubber at the double bonds, and not an adsorption phenomenon. The distillation of both rubber and hydro-caoutchouc in a high vacuum, 0·1 to 0·3 mm., was studied. The latter, being a saturated substance, needs a higher temperature than rubber. The products obtained from rubber were isoprene, dipentene, a hydrocarbon, $C_{15}H_{24}$, containing two double bonds, probably a hydrogenated naphthalene derivative, and hydrocarbons $C_{20}H_{32}$ and $C_{25}H_{40}$. The decomposition products from hydro-caoutchouc had the composition $(C_5H_{10})_n$, the lowest obtained being a pentene and the highest $C_{50}H_{100}$. All these observations are in agreement with the theory that the rubber molecule consists of isoprene molecules condensed in a chain of the following type:—



$$\cdots CH_2 \vdots CH_2.\overset{CH_3}{\dot{C}}{=}CH.CH_2 \vdots CH_2.\overset{CH_3}{\dot{C}}{=}CH.CH_2 \vdots CH_2 \cdots \text{etc.}$$

The vertical dotted lines indicate where splitting of the molecule may occur. Rubber separated from latex by means of acetone, then extracted with a mixture of chloroform and acetone, and hydrogenated gave the same results as plantation rubber. (*Cf.* J.C.S., Nov.)—E. H. R.

Rubber latex; Experiments to preserve ——. H. P. Stevens. Bull. Rubber Growers' Assoc., 1922, 4, 457—458.

Ammonia, sodium fluoride, sodium silicofluoride, "Agrisol A" and "Agrisol B" (cresol preparations) were found to be satisfactory preservatives; the three last-named, however, were used in conjunction with caustic soda, which itself exerts a marked effect. Ammonium carbonate, pyridine, sodium carbonate, formalin, sodium sulphite, Izal, carbolic acid, and cresylic acid (the three last with alkali) were unsatisfactory. Ammonia is effective when added in the proportion of ¼ oz. of concentrated solution to one quart of latex, but it is advisable to use twice this quantity; the proportion of caustic soda used was 2¼ pts. of "saturated solution" to 100 pts. of latex, but a much smaller proportion would probably suffice. For some manufactures preservation with the volatile ammonia may be advantageous, but for the majority of purposes latex preserved with caustic soda would be just as good.—D. F. T.

Patents.

Cellular [rubber] material; Process of producing ——. K. H. Fulton. E.P. 185,477, 25.5.21.

A mixture of raw rubber, sulphur or other vulcanising agents, and finely divided charcoal is shaped into the desired form and treated under high pressure in a jacketed vessel with an inert gas such as nitrogen, whereby the gas is occluded in the particles of charcoal without changing the size of the mass. While still under pressure, the material is vulcanised and subsequently cooled by the admission first of steam or hot water, and then of a cooling medium into the outer jacket. The pressure is then reduced to 1 atm., and the material is again heated, whereby the occluded gas is liberated from the particles of charcoal, causing the mass to swell and assume a cellular structure. A hard cellular material is prepared by using Para rubber and an excess of sulphur, and only carrying the vulcanisation at first to the stage at which a soft, cellular rubber is formed, this being subsequently hardened by further heating, *e.g.*, in a press if smooth boards suitable, *e.g.*, for lining refrigerators are required. In the manufacture of tyre fillers and the like, the original mixture contains balata in addition to Para rubber, and fibrous filaments run through the material from end to end to facilitate contact between the gas and the charcoal. The final heating is performed with the tyre mounted on a rim.—L. A. C.

Vulcanised oil product. U.S.P. 1,430,034. *See* XII.

XV.—LEATHER; BONE; HORN; GLUE.

Formaldehyde-tanned leather; Chroming of ——. E. Griliches. Collegium, 1922, 199—201.

The adsorption of chromium by hide is not appreciably affected by a preliminary treatment with formaldehyde. It was much higher with normal chromium sulphate than with basic chromium solutions. The acidity of chrome tanning liquors was much higher after chroming formaldehyde-treated leather than after direct chrome tannage. The amount of acid taken up by the formaldehyde-tanned leather as compared with pelt showed a decrease of 19—31%. The results confirm the results of Stiasny and Gerngross (*cf.* J., 1920, 730 A) on the diminution in the absorption of acid by formaldehyde-treated hide powder.—D. W.

XVI.—SOILS; FERTILISERS.

Kaolin; Decomposition of —— *by organisms.* W. J. Vernadsky. Comptes rend., 1922, 175, 450—452.

Silicious diatoms accompanied by a large number of bacteria were placed in contact with clay in a nutritive medium (free from silicon) contained in a glass vessel the interior of which was lined with paraffin wax. It was found that the development of the organisms was associated with the formation of hydrated aluminium oxide, whereas in the control experiment no chemical change in the clay could be detected. The author suggests that this decomposition of silicate plays a considerable part in natural processes.—H. J. E.

Microbiological analysis of soil as an index of soil fertility. I. The mathematical interpretation of numbers of micro-organisms in the soil. S. A. Waksman. Soil Sci., 1922, 14, 81—101.

The reliability of bacterial counts when only 2 or 3 plates are used is small. Large numbers of plates should be used and the limit of error calculated. The dilutions used for counting bacteria are too high for the counting of fungi. About 1/100th dilution should be used for the latter and a special acid medium is necessary. More than one sample of soil should be taken and a composite sample drawn from among the field samples. A scale of relative reliability based on the number of samples drawn and the number of plates made is suggested. —A. G. P.

Micro-organisms in soil; Tentative outline of the plate method for determining the number of ——. S. A. Waksman and E. B. Fred. Soil Sci., 1922, 14, 27—28.

The standard method of enumerating soil micro-organisms suggested by the Society of American Bacteriologists is outlined. The media included are albuminate-agar, caseinate-agar, and soil extract-agar-gelatin. The reaction of the medium is to be adjusted to about p_H 6·8 or 6·5 after sterilisation. From 5 to 10 plates for each dilution per sample are recommended, and the number of colonies per plate counted should be between 50 and 150. The incubation temperature is 28°—30° C., except for gelatin; and the period, 8—10 days for bacteria, 14 days for actinomycetes, and 2—3 days for fungi on synthetic media.—A. G. P.

Legume bacteria; Movement of —— *in soil.* W. C. Frazier and E. B. Fred. Soil Sci., 1922, 14, 29—36.

From a study of soya beans inoculated and uninoculated with the legume bacteria, and grown in close proximity, it is concluded that the organisms move extremely slowly or not at all in soil. —A. G. P.

Soil colloids; Influence of —— on availability of salts. N. E. Gordon and E. B. Starkey. Soil Sci., 1922, 14, 1—7.

The adsorption of calcium and potassium salts by silica, iron, and alumina gels was investigated. The amount adsorbed increased, within limits, with the concentration of the salt solution. Iron and alumina gels have a considerably greater adsorptive power than silica gels. Adsorbed salts are very slowly removed from the gels by washing. The adsorption of calcium and potassium ions increases with increasing p_H values of the solutions. With the phosphate ion the reverse in the case. Change of p_H value produces considerably greater adsorption changes with potassium salts than with calcium salts.—A. G. P.

Nitrate nitrogen and p_H values of soils; Variation of —— from the nitrogen availability plots. A. W. Blair and A. L. Prince. Soil Sci., 1922, 14, 9—17.

Plots which had received various fertiliser treatments were examined periodically for nitrates and p_H values. The variation of p_H value due to fertilisers was very small on limed plots, but considerable where lime was lacking. Limed plots gave consistently higher p_H values than the unlimed. Ammonium sulphate produced the lowest p_H values in both series. The plot having the lowest p_H value showed the greatest lime requirement by the Veitch method, whilst soils with p_H 7 showed no lime requirement. Nitrate figures were at their lowest immediately after the removal of crops, and were always higher on the unlimed plots, but there was no correlation between the nitrate figures and the crop yields. Soils sufficiently acid to inhibit the growth of ordinary farm crops had very considerable nitrate contents. Nitrification decreased with temperature. Excess of available nitrate caused " lodging " of grain crops.—A. G. P.

Fertility of rice soils; Possible correlation between the —— and their titration curves. O. Arrhenius. Soil Sci., 1922, 14, 21—26.

Attempts to correlate the productivity of rice soils and their hydrogen ion concentrations were unsuccessful. Titration of soil extracts, however, showed that those soils which possessed the greater buffer capacity were the more productive. Buffer capacity was measured directly by the amounts of acid or alkali which a soil could take up without appreciable alteration in p_H value.—A. G. P.

Rock phosphate; Composting —— with sulphur in slightly alkaline calcareous soils. W. Rudolfs. Soil Sci., 1922, 14, 37—59.

The conditions governing the oxidation of sulphur in soils and the subsequent solution of added rock phosphate have been examined with a view to the commercial utilisation of the process. In a calcareous soil the oxidation of sulphur proceeded normally, and the solution of the phosphate was not retarded. Increased temperature of incubation increased the rate of oxidation and solution of phosphate, and in a calcareous soil the influence of temperature was much more evident when large amounts of soil were used. Light was slightly detrimental to the sulphur-oxidising organisms, bacterial activity was stimulated by small amounts of sulphuric acid, and by sodium carbonate in a calcareous soil poor in organic matter. In a richly organic soil sodium carbonate had no stimulating effect. Sodium bisulphate solution, acetic acid, ferrous sulphate, and aluminium sulphate failed to act as stimulants to the organisms; and sodium chloride, and, to a less extent, hydrochloric acid retarded their activity. Partial sterilisation of the soil had no beneficial effect. The amount of soil used may be reduced to 1·6—1·7%, and ammonium sulphate may be used to replace the bulk of calcareous soil poor in nitrogen. The use of sulphur in quantities comparable to the amount required in the commercial manufacture of superphosphate gave good results. The addition of sulphurous acid to produce an acid reaction at the commencement of the process considerably increased the rate of oxidation. Aeration of the mixture increased the rate of reaction, but too much air caused it to cease almost entirely. The hydrogen ion concentration at the completion of the process reached p_H 3·1—2·9, but the titratable acidity increased after this point was reached. The mixtures tended to form aggregates which varied in acidity and in available phosphate content according to their size.—A. G. P.

Potato scab; Influence of soil reaction upon the growth of actinomycetes causing ——. S. A. Waksman. Soil Sci., 1922, 14, 61—79.

Actinomyces scabies will grow in acid soils up to p_H values of 5·0—5·2, with occasional strains surviving at p_H 4·8. The saprophytic soil actinomycetes are more resistant than strains of *A. scabies*. It is possible, by treating soil with sulphur inoculated with *Thiobacillus thiooxidans*, to increase the acidity sufficiently to control the growth of *A. scabies*.—A. G. P.

Cobalt and nickel in plants. Bertrand and Mokragnatz. *See* XIXA.

Patents.

Lime-nitrogen [crude calcium cyanamide] process and product. J. M. A. Stillesen. U.S.P. 1,386,445, 2.8.21. Appl., 8.8.11. Renewed 30.11.17.

Crude calcium cyanamide is treated with water and then with carbon dioxide to convert the free lime into basic or normal calcium carbonate. To avoid risk of decomposition of the calcium cyanamide by the heat of the reaction, solid or liquid carbon dioxide is preferably used, the heat evolved in the union of lime and carbon dioxide being thus counteracted by the heat absorbed in the vaporisation and expansion of the carbon dioxide.

Fertiliser material and process of producing same. A. F. Hoffman. U.S.P. 1,428,633, 12.9.22. Appl., 23.4.18.

A fertiliser material containing basic ferric sulphate and organic matter is precipitated from acid coal mine water by partial neutralisation. —T. A. S.

Fertiliser; Treatment of calcium cyanamide for production of a ——. Bambach und Co. Chem. Ges.m.b.H. G.P. 300,022, 30.12.13. Addn. to 299,131.

A solution of sodium ammonium sulphate, prepared as described in the original patent (*cf.* p. 858 A), is treated with superphosphate, so as to produce a solution of sodium ammonium phosphate, which, on evaporation, yields a fertiliser. —A. B. S.

XVII.—SUGARS; STARCHES; GUMS.

Beet juice; Action of lime on the protein substances separated during the defecation of ——. V. Stanek. Z. Zuckerind. Czechoslov., 1922, 46, 663—669, 671—676.

Raw beet juice was limed and heated, and the effect of this treatment on the proteins thus precipitated was studied. It was found that under the conditions of liming in practice, about 11% of the precipitate may pass into solution, but part will be re-precipitated on carbonating. This hydrolytic action of lime was found to result in the formation of albumoses, peptones, and polypeptides, but it was not possible to isolate amino-acids. Decomposition products of lecithin, *e.g.*, glycerophosphoric acid and choline, were detected. Betaine could not be identified.—J. P. O.

Sucrose; Correction for the volume of the lead precipitate when using basic lead nitrate as clarifying agent in determination of ——. C. Sijlmans. Archief Suikerind. Nederl.-Indië, 1922, 30, 517—520. Int. Sugar J., 1922, 24, 496.

In the method of operating the double polarisation method recently described (J., 1921, 863 A), in which lead nitrate followed by sodium hydroxide is employed for clarification, a considerable precipitate is produced, for which it is necessary to make an allowance. This is done by making two polarisations, the new method of clarification being applied in both, but a determined amount of sucrose added in the second. In this way the volume of the lead precipitate was found to amount to 3·2 c.c. per 100 c.c., causing the result in the case of molasses to average about 1·26% too high.—J. P. O.

Sucrose; Estimation of —— *in presence of other sugars by means of the hydroxides of the alkaline earths.* A. Behre and A. Düring. Z. Unters. Nahr. Genussm., 1922, 44, 65—70.

Sucrose is estimated by heating the material (20 g.) with 1·2 g. of lime and 50 c.c. of water for 1 hr. at 60°—80° C. Other sugars are thus destroyed and the sucrose is determined polarimetrically. Barium hydroxide (4 g.) may be substituted for the lime, but in this case heating for 2 hrs. under a reflux condenser is necessary. With a 200-mm. polarimeter tube the sucrose content is given by the formula P×0·75×5.—A. G. P.

Sucrose, dextrose, lævulose, and invert sugar; Relative sweetness of ——. N. Deerr. Int. Sugar J., 1922, 24, 481.

Solutions of various sugars were diluted until they had the same sweetness as that of a 10% solution of dextrose. The following results for relative sweetness were thus obtained: sucrose, 100; dextrose, 60; lævulose, 120; and invert sugar, 95. The difference between this result for invert sugar and that obtained by Sale and Skinner (J., 1922, 776 A) may be due to the different concentration at which the liquids were tasted.—J. P. O.

Glucose-ammonia and iso-glucosamine; Crystalline ——. A. R. Ling and D. R. Nanji. Chem. Soc. Trans., 1922, 121, 1682—1688. (*Cf.* J., 1922, 151 T.)

The crystalline compound obtained by the action of ammonia on dextrose in methyl alcoholic solution is glucose-ammonia, and is identical with the product obtained in aqueous solution (*loc. cit.*). It melts at 123°—124° C., and has $[\alpha]_D = +20{\cdot}3°$. It gives all the reactions of an aldehyde-ammonia, including the formation of a primary amine on reduction, glucamine being produced when a solution in 95% methyl alcohol is subjected to cathodic reduction. Further confirmation of the structure of glucose-ammonia was obtained by condensing it with formaldehyde sodium bisulphite, when an ω-sodium sulphonate,

$$HO.CH_2.[CH(OH)]_4.CH(OH).NH.CH_2SO_3Na,$$

was formed. On recrystallising glucose-ammonia from methyl alcohol it loses 1 mol. of water with the formation of isoglucosamine, m.p. 127°—128° C. —G. F. M.

Starch; New depolymerisation product of ——. A. Pictet and R. Jahn. Helv. Chim. Acta, 1922, 5, 640—644.

When potato starch is heated in glycerin at 200°—210° C., until a sample no longer gives a colour with iodine, a new compound is formed which can be isolated by distilling off the glycerin under 2—4 mm. pressure, dissolving the residue in water, and precipitating with alcohol. The product, to which the name trihexosan is given, has the formula $(C_6H_{10}O_5)_3$, and forms a white, amorphous, slightly hygroscopic powder, $[\alpha]_D = +162{\cdot}2°$ in water. It does not reduce boiling Fehling's solution, is hydrolysed by hot dilute sulphuric acid to glucose, and forms a nonoacetyl derivative,

$$[C_6H_7O_5(C_2H_3O)_3]_3,$$

m.p. 153°—154° C. It is not identical with either of Pringsheim's triamyloses (J., 1913, 985). The existence of this compound supports the view that the starch molecule contains $C_6H_{10}O_5$ units combined in groups of three.—E. H. R.

Patents.

Sugar manufacture; System of pan boiling in —— *by using an auxiliary storage tank.* T. C. Jacobs. In part from H. M. Jacobs. E.P. 185,707, 30.3.22.

An auxiliary tank is connected with the vacuum pan system in a sugar factory and means are provided for the automatic transfer of the whole or part of the contents of any vacuum pan to the auxiliary tank for treatment by stirring or otherwise keeping it in motion while it is gradually cooling and for the automatic transfer of the virgin grain in the tank to any vacuum pan requiring "footing" for massecuites. This enables vacuum pans to be supplied with virgin grain which would otherwise be idle.—H. C. R.

Sugar juices; Process for purifying —— *by filtration and decantation.* F. Tiemann. U.S.P. 1,430,200, 26.9.22. Appl., 6.7.21.

See E.P. 161,987 of 1921; J., 1921, 633 A.

XVIII.—FERMENTATION INDUSTRIES.

Amylases of the cereal grains. The "insoluble" amylase of barley. J. L. Baker and H. F. E. Hulton. Chem. Soc. Trans., 1922, 121, 1929—1934.

The water-insoluble amylase of barley which is liberated by proteolytic action is associated with the alcohol-soluble group of proteins (hordein), since papain liberated amylase from the water-extracted residue, and from the residue after salt extraction (globulin-free material), but not from the residue from which hordein had been removed by alcohol. Since no amylase could be obtained by the action of papain on isolated hordein, nor from barley which had been boiled or heated to 120° C., it is concluded that the enzyme was pre-existent in the barley as an insoluble enzyme complex, and is not a cleavage product of some non-amylolytic protein. Amylase liberated by papain invariably exhibits only the characteristic properties of the soluble amylase of barley, and no light is therefore thrown on the appearance of the characteristic malt amylase during the germination of barley.—G. F. M.

Methyl alcohol; Detection of —— *in alcoholic drinks.* J. F. A. Pool. Pharm. Weekblad, 1922, 59, 973—979.

The method of Trillat and Wolff (J., 1900, 565), namely oxidation with bichromate, shaking with dimethylaniline, and oxidation of the aldehyde-aniline condensation product with lead peroxide, is capable of detecting 1 pt. of methyl alcohol added to 2000 pts. of various wines and spirits; about the same sensitiveness is obtained by the method of Fendler and Mannich (J., 1905, 1128), viz, oxidation with permanganate after distillation, and addition of morphene hydrochloride in strong sulphuric acid solution. Of 200 samples tested by these two methods, none showed methyl alcohol except in those cases in which it was added purposely. Methyl alcohol does not reduce permanganate more quickly than ethyl alcohol, as generally stated; this is true only of wood spirit, which contains aldehydes and other reducing agents.—S. I. L.

Yeasts from butter. Sandelin. *See* XIXA.

XIXA.—FOODS.

Wheat gluten. J. Gerum and C. Metzer. Z. Unters. Nahr. Genussm., 1922, **44**, 86—89.

Experiments are described which throw doubt on the existence of a stable insoluble compound of protein and phosphoric acid in wheat gluten. (*Cf.* Levy, Z. Unters. Nahr. Genussm., 1910, **19**, 120.) In the preparation of gluten from flour, temperature and amount of washing have little influence on the yield or physical properties of the protein. The greater part of the phosphorus in flour is washed out during the separation of the gluten. The maximum amount of phosphorus retained by the gluten was 22% of the total. By mixing rye with wheat flour the phosphorus in the gluten prepared from it was decreased. Fineness of milling also causes a reduction in the phosphorus content of the gluten. In mixed rye and wheat flours the yield of gluten decreases parallel with its phosphorus content. The ratio of phosphorus to nitrogen in gluten from pure wheat flour varies within certain limits and decreases proportionally to the amount of added rye flour. If, instead of rye, neutral indifferent substances are added to wheat flour, the yield of gluten and its phosphorus content appear to depend on the physical properties of the added material.—A. G. P.

Wheat gliadin; Rate of hydrolysis of ——. H. B. Vickery. J. Biol. Chem., 1922, **53**, 495—511.

Results are given of a large number of experiments in which measurements were made of the rate of hydrolysis of gliadin by acids of various concentrations and also by alkalis. Hydrolysis both of the amide nitrogen and of the peptide linkages proceeds more rapidly the higher the concentration of acid. In the early stages, alkalis are more effective than acids. Owing to secondary decompositions, however, considerably larger quantities of ammonia are liberated by alkalis than by acids. Hydrolysis is more rapid with barium hydroxide than with sodium hydroxide of equivalent concentration. —E. S.

Maize flour; Biochemical reaction of stale ——. J. Vintilesco and M. Haimann. Bul. Soc. Chim. Romania, 1922, **4**, 17—20. Chem. Zentr., 1922, **93**, IV., 765—766.

Commercial maize flour always has a slightly rancid taste and its behaviour on testing by Vintilesco and Popesco's reaction with hæmoglobin and guaiacum tincture (J. Pharm. Chim., 1910, **12**, 318) for rancid fats indicates that the rancidity is due to oxidation of the unsaturated fatty acids, which are present to a greater extent in maize than in wheat. Freshly milled maize flour and samples that have been kept in the dark in well-sealed vessels give a negative result with this test. If, however, the flour is exposed to the air, whether in sunlight or in the dark, the reaction becomes positive after a few days. The oil extracted from the flour with petroleum spirit reacts in the same way as the flour itself. That from the fresh flour had an iodine value of 119, while that from the flour after several days' exposure to the air had an iodine value of 102. Wheaten flour contains an oxidase which colours guaiacum tincture in the absence of hæmoglobin, and the test is therefore inapplicable.—H. C. R.

Water in meat sausages; Detection of added ——. S. Holzmann and J. Deininger. Z. Unters. Nahr. Genussm., 1922, **44**, 81—86.

The method of Feder (Z. Unters. Nahr. Genussm., 1913, **25**, 577) for the determination of added water in meat products was examined, and attempts were made to curtail the routine estimation of water, fat, and ash, and the subsequent calculation of added water. The meat ash (free from sodium chloride) was found to be uniformly 4—5% of the non-fatty organic matter. Sodium chloride may be estimated by extracting the shredded meat (5 g.) with 50 c.c. of distilled water for ½ hr. on a water bath and for 5 mins. over a free flame. The extract is neutralised and chlorides estimated volumetrically. A reliable figure for total mineral matter may be obtained by adding to the sodium chloride thus obtained, 4—5% of the non-fatty (protein) nitrogen. In a series of tests the non-fatty organic matter of meats was found to approximate fairly closely to the protein figures as determined by the Kjeldahl method. Cases of divergence may be due to changes in the character of the protein during digestion and the consequent invalidation of the protein factor 6·25. Added water in meat preparations cannot be estimated with very great accuracy by calculation based merely on an estimation of water and nitrogen, and in cases of dispute it is advisable to carry out the Feder method in its entirety. —A. G. P.

Butter and other edible fats; Semi-microchemical determination of water, fat, and sodium chloride in ——. H. Lührig. Pharm. Zentralh., 1922, **63**, 505—508.

For the determination of water the Perplex method is employed, using an ordinary analytical balance and small aluminium beakers with lip and handle or small porcelain casseroles. About 1 g. of butter or margarine is used for each test. In the case of margarine the danger of spirting is reduced by adding a little coarse pumice powder. The whole determination only takes 5—6 min., and very close agreement is obtained between the tests and in comparison with other methods. The fat is determined by extracting the residue in the beaker after the water has been boiled off, with anhydrous ether and filtering the extract into a weighed 50 c.c. conical flask, distilling off the ether, and heating to constant weight in a current of air in an oven. The residue after extraction of the fat is extracted with lukewarm water and washed on the same filter as that used for the ether extract. The sodium chloride is determined in an aliquot part of the filtrate by titration with silver nitrate in the usual way, the concentration of the silver nitrate being such that 1 c.c.=1 mg. Cl. All three determinations can be carried out in about 1 hr. —H. C. R.

Yeast types isolated from butter; Action of —— *on the constituents of milk.* A. E. Sandelin. Ann. Acad. Sci. Fennicae, 1922, **A 19**, [3]. Chem. Zentr., 1922, **93**, III., 838.

Various types of yeast isolated from butter (*cf.* Ann. Acad. Sci. Fennicae, Series A, **12**, No. 6) were examined with regard to their action on the various constituents of milk both when grown alone and in mixed cultures with *Streptococcus lactis*. All the yeasts used were *Torulæ* according to Hansen's classification with one exception, which was a *Mycoderma*. The yeasts could be divided into groups according to their action on the constituents of milk. No type was found to act on all the constituents of milk—fat, sugar, and casein. —W. H. G.

"Cyclon"; Absorption of —— by different foodstuffs. [Detection of hydrocyanic acid.] J. D. Jansen, W. Schut, and M. Wagenaar. Chem. Weekblad, 1922, **19**, 373—375.

Various foodstuffs left exposed during the fumigation of a liner were found to contain up to 700 mg. HCN per kg., the greatest absorption being found for meat and water, and nothing detectable in coffee and mustard. The analyses were based on colorimetric determinations by means of phenolphthalein, which is regenerated from the colourless reduction product by hydrocyanic acid in presence of copper acetate. The reaction will detect 0·001 mg. HCN.—S. I. L.

Boric acid in shrimps; Estimation of ——. W. M. Deerns. Chem. Weekblad, 1922, **19**, 397—400.

In the estimation of boric acid in foodstuffs by the usual method the presence of phosphates causes incorrect results. To estimate the error arising through the presence of phosphates, shrimps were mixed with a known quantity of boric acid and sodium bicarbonate, dried, and ignited in a muffle. The ash was lixiviated with water. The solution was acidified with a few drops of hydrochloric acid and boiled in a flask fitted with a reflux condenser for 20 mins. The solution was neutralised with baryta and the last traces of acid removed by a solution of potassium iodide and iodate. The boric acid was then titrated with potassium hydroxide free from carbon dioxide in presence of mannitol. In a series of experiments too much boric acid to the extent of 0·40—0·53% was indicated. The amount of phosphates in shrimps is 0·4—0·6%. The analysis of shrimps to which no boric acid had been added gave an indication of the presence of 0·59—0·57% of boric acid. To avoid the error due to phosphates, after ignition and treatment with hydrochloric acid, a solution of ferric chloride was added and the liquid neutralised with chalk and filtered. 200 c.c. of the solution was drawn off by a pipette and the test continued as described. The results obtained were correct to within 1%.—H. M.

Cobalt and nickel; Presence of —— in plants. G. Bertrand and M. Mokragnatz. Comptes rend., 1922, **175**, 458—460.

An examination of various food products of vegetable origin for traces of nickel and cobalt showed that the former is present in every case, whilst the latter is absent only from carrot and oats; further investigation may reverse the negative result obtained in these two cases. The substances examined consisted of carrot (root), onion (bulb), potato (tuber), spinach (leaf), lettuce (leaf), cress (stem with leaf), tomato (fruit), apricot (fleshy part of fruit), bean (whole green pod, also dried seed), lentil (grain), buckwheat (grain), wheat (grain, also husk), oats (grain), maize (grain), rice (polished grain), mushroom (whole). The quantity of metal per kg. of fresh substance varies in the case of nickel from 0·01 mg. to 2 mg. and in the case of cobalt from 0·005 mg. to 0·3 mg.—H. J. E.

Alfalfa [lucerne] plant; Water-soluble constituents of the ——. T. B. Osborne, A. J. Wakeman, and C. S. Leavenworth. J. Biol. Chem., 1922, 53, 411—429.

The investigation of the press-juice previously obtained (J., 1922, 74 a) has been continued. After removal of the colloid obtained by addition of 20% of alcohol, a second precipitate may be obtained by raising the alcohol content of the filtrate to 53%. This precipitate contains 8% of the original nitrogen, which is probably present as protein. The distribution of nitrogen, both before and after hydrolysis, has been determined in the two precipitates and also in the filtrate, and analyses have been made of the inorganic constituents of the three fractions. The filtrate appears to be suitable for investigating the water-soluble constituents of the juice; the present paper records preliminary experiments in this direction.—E. S.

Proteins of the lima bean, Phaseolus lunatus. D. B. Jones, C. E. F. Gersdorff, C. O. Johns, and A. J. Finks. J. Biol. Chem., 1922, 53, 231—240.

The lima bean contains 21·17% of protein (N × 6·25). By extraction with sodium chloride solution, an α- and a β-globulin were obtained, which were separated by fractional precipitation with ammonium sulphate. An albumin was also isolated. Analyses by Van Slyke's method gave the following values for basic amino-acids: α-globulin—cystine 1·60, arginine 5·67, histidine 3·71, lysine 7·84%; β-globulin—cystine 0·84, arginine 5·07, histidine 2·62, lysine 8·53%; albumin—cystine 1·07, arginine 5·74, histidine 2·54, lysine 5·97%. Positive tests were obtained for tryptophan in each case. The proteins of the lima bean are, in general, similar to those of other beans of the genus *Phaseolus* (*cf.* J., 1922, 342 a).—E. S.

Vitamin which promotes calcium deposition; Experimental demonstration of the existence of a ——. E. V. McCollum, N. Simmonds and J. E. Becker. J. Biol. Chem., 1922, 53, 293—312.

When heated for 12 to 20 hrs. in the presence of oxygen, cod liver oil no longer cures xerophthalmia in rats; its property of initiating healing in rickets, however, is not appreciably reduced. This treatment apparently destroys vitamin A but leaves intact the anti-rachitic factor, which must consequently be regarded as a fourth vitamin. Cod liver oil, shark liver oil, turbot liver oil, and butter cure xerophthalmia and also stimulate the deposition of calcium; coconut oil is deficient in vitamin A, but initiates healing in rickets; whilst cottonseed oil, maize oil, sesamé oil, and olive oil are deficient in both vitamin A and the anti-rachitic factor.—E. S.

Patents.

Food; Manufacture of ice and the use thereof for preserving ——. W. E. Gibbs. E.P. 185,986, 28.10.21.

Sodium hypochlorite in small concentration (*e.g.*, 0·025%) is added to water which is then converted into ice. Such ice is especially suitable for the preservation of fish. Other soluble hypochlorites may be used provided that they possess sufficient germicidal properties to exert a sterilising action on the fish when the ice melts and that they do not affect the appearance of the fish or impart an unpleasant flavour to it. Dilute chlorine water may also be frozen and used in a similar manner, but to prevent corrosion of iron containers from any acids formed the water should be made alkaline.—J. R.

Wheaten [flour]; Method of blending ——. C. G. Harrel, Assr. to The Campbell Baking Co. U.S.P. 1,429,504, 19.9.22. Appl., 6.9.21.

The fermentation of dough for baking purposes is controlled by determining the hydrogen ion concentration of the flour and permitting the dough in which the flour is incorporated to stand for a period of time having a definite relation to the hydrogen ion concentration.—J. R.

Dough; Method of determining condition of —— for baking products during fermentation process. C. J. Patterson, Assr. to The Campbell Baking Co. U.S.P. 1,429,526, 19.9.22. Appl., 29.8.21.

The condition of dough for baking products is ascertained by determining the hydrogen ion concentration of the mixed dough after fermentation has proceeded for a suitable time.—J. R.

Milk; Process and apparatus for acting upon ——. F. A. Plummer, Assr. to A. D. Gray. U.S.P. 1,430,403, 26.9.22. Appl., 28.4.20.

An apparatus for producing dried products from liquids, such as milk, consists of a vertical casing, the lower part of which is surrounded by a second casing. Air is introduced in tangentially oblique currents at the top of the cell, and meets the finely divided liquid under treatment, which is also introduced at the top. The current of air and suspended matter moves rapidly downwards in a cyclone and is discharged through numerous fine openings into the second chamber, which is provided with means whereby the air continues its cyclonic movement, with the result that the solids produced by evaporation of the particles of liquid are acted upon by centrifugal force and gravity and are separated from the air.—J. R.

Baking powder. B. Bleyer. G.P. 356,168, 1.4.20.

The powder comprises a mixture of a salt, such as sodium bicarbonate, which evolves gas on heating, and a compound of casein and lactic acid (*cf.* G.P. 344,707; J., 1922, 432 A). The product has a pleasant taste, is not hygroscopic, and evolves large quantities of carbon dioxide.—H. C. R.

Baking or drying substances. E.P. 185,460. *See* I.

XIXb.—WATER PURIFICATION; SANITATION.

Disinfectants; Standardisation of ——. K. Rülke. Chem.-Zeit., 1922, **46**, 897—898.

Attention is drawn to the greatly differing figures for the disinfecting power, or carbolic acid coefficient, of a disinfectant given by the Rideal-Walker test using an ordinary sterilised broth on the one hand, and milk or similar emulsion on the other. Where, for example, in the former case 0·1% of a solution of higher phenols had the same effect as 1% of carbolic acid, in the latter case a 1·25% solution of carbolic acid and 1·4% solution of the higher phenols was required. The same discrepancy is found in the case of determinations of the antiseptic power. Kobert's method of determining the antiseptic power in milk to which colloidal sulphur has been added, using bacteria which produce hydrogen sulphide, and finding the amount of disinfectant required to prevent the formation of this gas within a certain time as indicated by lead acetate paper, is recommended for use where a bacteriological laboratory is not available. A disinfectant can be sufficiently characterised by means of a curve for the disinfecting or germicidal power at 17·5° C., and a second curve for the antiseptic power under the usual conditions, but one curve alone is not sufficient. Further, a disinfectant should be standardised in respect to the particular bacteria for the destruction of which it is to be used in practice.—G. F. M.

Patents.

Turbid water or liquid; Filtration of ——. R. H. L. Pennell. E.P. 185,798, 11.5.21.

In a water purification plant especially suitable for small towns, pre-filtration is effected in stages by passing the liquid through a number of chambers containing graded filtering medium. The rate of flow of the liquid through each successive chamber is decreased by successively increasing the area of the respective chambers. The water to be filtered is led into a well which it leaves at or near the bottom and passes upwards through a catch pit wherein coarse foreign matter is deposited and from which the liquid traverses in succession a number of scrubbing and straining vessels, the liquid in each case percolating upwards before finally percolating downwards through one or more sand filters. The last filtering stage consists of sand filtration tanks working in parallel. The water is admitted from the last of the strainers to the upper surface of the sand constituting the filtering medium and passes downwards to outlet wells in communication with the bottom of the tanks. —J. R.

Sewage; Purification of —— by treatment in centrifugal separators. E. Green. E.P. 185,444, 2.4.21.

The perforated basket of a centrifugal machine is lined with segmental bags filled with porous material (*e.g.*, charcoal in asbestos bags) to form a filtering medium. When the layer of sediment is of a certain thickness, the admission of sewage is stopped automatically and the machine allowed to run to dry the cake, which when dry is broken up by a squeegee or scraper and discharged through a suction pipe without stopping the machine. The filtering medium is easily removable; when clogged it is removed and rendered permeable again by heating to a high temperature.—B. M. V.

[Sewage] sludge; Dehydrating activated ——. C. L. Peck, Assr. to The Dorr Co. U.S.P. 1,430,182, 26.9.22. Appl., 17.3.21.

The sludge is made slightly acid to methyl orange under conditions which result in gas evolution. The solid material in the sludge thereby gradually rises to the surface and forms a floating mass, of which a considerable part is above the liquid level of the sludge. Solid matter is then withdrawn from this portion of the floating mass to any desired extent. —J. R.

Disinfecting and preserving; Process for —— [with colloidal aluminium hydroxide]. E. de Haën, Chem. Fabr. "List" G.m.b.H., and M. Buchner. G.P. 356,833, 30.3.19.

Colloidal aluminium hydroxide containing a high percentage of water is prepared by adding concentrated ammonia solution to a cold 2% solution of an aluminium salt, and subsequently heating the mixture. The product on application to open wounds builds a thick scab without formation of pus, and exerts a bactericidal action due to adsorption.—L. A. C.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Morphine content of powdered opium; Loss in —— on storage. H. E. Annett and H. D. Singh. Pharm. J., 1922, **109**, 304—305.

Samples of dry powdered opium stored for four years lost about 3% of morphine calculated on the dry weight of the opium, the amount of the loss being irrespective of the original morphine content. The destruction of the morphine may possibly be due to the action of oxidising enzymes, which have been shown to be present. There is considerable evidence that moist opium does not undergo any change on storage.—G. F. M.

Atropine; Volatilisation and hydrolysis of —— in toxicology. P. Hardy. J. Pharm. Chim., 1922, 26, 220—226.

Considerable losses of atropine take place in aqueous solution in consequence of hydrolysis and also by reason of the fact that the alkaloid is volatile in steam. With suitable methods of extraction, however, these losses may be obviated and accurate estimations of atropine may be made if proper precautions are taken.—H. J. E.

Yohimbine; Determination of —— in yohimbé bark. A. Schomer. Pharm. Zentralh., 1922, 63, 385—386.

A method described previously (J., 1921, 320 A) yields better results, especially in the case of barks of low yohimbine content, when the yohimbine hydrochloride is crystallised from a cold solution. The brown residue containing the hydrochloride (obtained as described) is treated with 5 c.c. of ether, the latter is evaporated, the residue then dissolved in 3 c.c. of cold absolute alcohol and the solution kept at 0° C. for 18 hrs. The crystals which form are collected, washed with chloroform, then with ether, dried at 100° C., and weighed. —W. P. S.

Amygdalin; The biose of ——. Constitution of the disaccharides. VI. W. N. Haworth and G. C. Leitch. Chem. Soc. Trans., 1922, 121, 1921—1929.

The methylation of amygdalin by means of methyl sulphate in presence of sodium hydroxide resulted in the formation of the methyl ester of heptamethylamygdalinic acid, a crystalline compound, m.p. 91° C., $[\alpha]^{15}_{D} = -51{\cdot}7°$ in ethyl alcohol. Graded scission of this compound by dilute acid gave three cleavage products, namely, *dl*-mandelic acid, tetramethylglucose of the usual butylene oxide form, and a trimethylglucose which was readily converted on the one hand into tetramethylglucose, and, on the other hand, by oxidation with dilute nitric acid into the lactone of trimethylsaccharic acid, indicating that both terminal positions in the hexose chain were unoccupied by methyl groups, and were therefore the positions of attachment of the aromatic complex and the other hexose residue. This evidence shows that the amygdalin biose is, apart from stereochemical reservations, structurally identical with maltose and quite definitely cannot be cellobiose. As regards the stereochemical formulation of the biose, the results based on the selective action of enzymes are somewhat anomalous, but favour the view that maltose is actually a glucose-α-glucoside, and amygdalin itself would then be mandelonitrile-β-maltoside. Should it ultimately be found, however, that the biose is a β-glucoside, this would not, of course, affect the structural formula above ascribed to the sugar, but it might point to its identity with isomaltose or gentiobiose.—G. F. M.

Saffron; Detection of colouring matter of ——, in investigations relating to laudanum poisoning. M. Guerbet. J. Pharm. Chim., 1922, 26, 218—220.

The facts that crocin, the colouring matter of saffron, gives an insoluble substance, crocetin, when hydrolysed by heating with acid, *e.g.*, dilute hydrochloric acid, and that crocetin gives with concentrated sulphuric acid an intense blue coloration changing to violet and brown, may be utilised for detecting poisoning by preparations of laudanum containing saffron. The method admits of the subsequent detection and estimation of meconic acid and the opium alkaloids in the solution from which the crocetin has been separated by filtration. —H. J. E.

Chemical constituents of green plants. XX. Acids present in the cherry (Prunus avium). H. Franzen and F. Helwert. Z. physiol. Chem., 1922, 122, 46—85.

Malic acid is much the most important acid of the cherry. There are present also traces of oxalic acid, and small quantities of succinic acid, citric acid, lactic acid, and of unsaturated acids. —W. O. K.

Muscarine; Isolation of ——, the potent principle of Amanita muscaria. H. King. Chem. Soc. Trans., 1922, 121, 1743—1753.

About 0·12 g. of pure muscarine aurichloride was isolated from 25·5 kg. of fresh *A. muscaria* after a long and tedious process which consisted essentially of several precipitations of the clarified alcoholic extract first with aqueous, and then with alcoholic mercuric chloride, and finally with phosphotungstic acid. The precipitated bases consisted chiefly of choline and muscarine in the proportion of about 20:1, and the former was largely removed by fractionation of the *d*-hydrogen tartrates. Fractionation was continued by means of the aurichlorides, and finally large delicate leaflets of pure muscarine aurichloride were isolated. The whole operation was controlled physiologically by following the distribution of activity by observations of the effects produced on an isolated loop of rabbit's intestine. Pure muscarine chloride was found to be about seven times as active as arecoline, and five times as active as acetylcholine. Physiological assay assigns a content of 0·4 g. of muscarine chloride to the extract from 25·5 kg. of fresh fungus. Muscarine chloride has a molecular weight of about 210; it is quite stable towards alkali and cannot therefore be an ester of choline, nor is there any evidence for the accepted formula with one oxygen atom more than choline, or that it is a quaternary base. It appears to be an alkaloidal base of considerable complexity.—G. F. M.

Animal nucleic acid; Preparation and analysis of ——. P. A. Levene. J. Biol. Chem., 1922, 53, 441—447.

The author's method for the preparation of animal nucleic acid has been improved. The ground glands (10 lb.) are boiled for 35 mins. with 5 l. of water containing 250 g. of sodium hydroxide. The mixture is then neutralised with acetic acid, treated with a colloidal solution of iron (50 c.c.), filtered, and left overnight. Addition of 2 vols. of methyl alcohol containing 2% of hydrochloric acid to the solution precipitates the nucleic acid. The method has been applied to thymus gland, spleen, kidney, pancreas, and liver. In the case of liver the product contains considerable amounts of glycogen and must be further purified. Nucleic acids from the above organs have the same elementary composition, which corresponds with that of a hexose tetranucleotide. Estimations of the purine bases also agree with the tetranucleotide theory.—E. S.

Mercuration in the aromatic series. II. Thymolmercuriacetates and their derivatives. E. Mameli and A. Mameli-Mannessier. Gazz. Chim. Ital., 1922, 52, II., 1—16. (*Cf.* J., 1922, 518 A.)

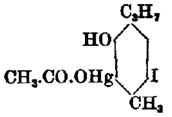
The action of mercuric acetate on thymol under various conditions yields, besides the thymoldimercuriacetate already known, also two new compounds, thymol-*o*- and thymol-*p*-monomercuriacetates,

$$C_3H_7.C_6H_2(OH)(CH_3).Hg.O.CO.CH_3.$$

A number of the corresponding salts in which the acetoxy group is replaced by another acid radicle, are also described. (*Cf.* J.C.S., Nov.)—T. H. P.

Mercuration in the aromatic series. III. Mercurated derivatives of p-iodothymol. E. Mameli. Gazz. Chim. Ital., 1922, 52, II., 18—23.

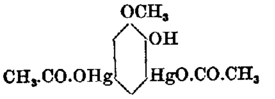
The action of mercuric acetate on *p*-iodothymol, which has only one free ortho-position with respect to the hydroxyl, readily yields the monomercuri-derivative, *p*-iodothymol-*o*-mercuriacetate,



from which the corresponding mercurichloride, mercuribromide, mercurihydroxide and internal oxide are obtainable. (*Cf.* J.C.S., Nov.).
—T. H. P.

Mercuration in the aromatic series. IV. Dimercurated derivatives of guaiacol. E. Mameli. Gazz. Chim. Ital., 1922, 52, II., 23—27.

The action of mercuric acetate on guaiacol yields mono- and di-mercuriacetates in proportions varying with the experimental conditions. Guaiacol-*o.p*-dimercuriacetate,



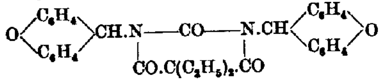
and the corresponding chloride, nitrate, and internal oxide are described. (*Cf.* J.C.S., Nov.)
—T. H. P.

Aniline arsenates. E. Paternò. Gazz. Chim. Ital., 1922, 52, II., 28—31.

When aniline is treated cold with aqueous arsenic acid it always yields dianiline arsenate, and this, when distilled either in a vacuum at 60° C. or in a current of steam or when left in a desiccator over sulphuric acid, loses aniline to form the monoaniline salt, m.p. 154° C. The melting point of the dianiline salt varies, for different samples and different methods of heating, from about 140° C. to about 150° C., and cannot be ascertained exactly, the salt readily undergoing change. In aqueous solution the monoaniline and dianiline salts are hydrolysed to two and three molecules respectively. The maximum solubility of aniline in water is about 3·7% at −0·6° C., and that of water in aniline about 2·8% at −5·4° C.—T. H. P.

Veronal and hypnotics derived from barbituric acid; Reaction of ——. R. Fabre. J. Pharm. Chim., 1922, 26, 241—249.

Veronal, and the malonylureas generally, readily condense with xanthydrol to form crystalline dixanthyl derivatives, *e.g.*,



$$O\left\langle{}^{C_6H_4}_{C_6H_4}\right\rangle CH.\underset{|\qquad\qquad\qquad}{N\text{———}CO\text{———}}\underset{|}{N}.CH\left\langle{}^{C_6H_4}_{C_6H_4}\right\rangle O \atop CO.C(C_2H_5)_2.CO$$

when boiled therewith for a few minutes in acetic acid solution. Similar derivatives are not formed by other hypnotics, and the reaction is therefore valuable for the characterisation and identification of the malonylureas. It can easily be carried out with as little as 0·01 g. of the hypnotic, or with the crude product as isolated by the usual methods from the viscera in toxicological investigations. The dixanthyl derivatives are easily characterised by their melting points, which may be directly determined on the crystals deposited from the acetic acid solution, after washing them with small quantities of boiling alcohol, recrystallisation being unnecessary. The melting points of the dixanthyl derivatives of the principal malonylureas are as follows:—veronal 245°—246° C., phenylethylmalonylurea (gardenal) 218°—219° C., diallylmalonylurea (dial) 242°—243° C.—G. F. M.

Methylguanidine and ββ-dimethylguanidine; Preparation of —— by the interaction of dicyanodiamide and methylammonium and dimethylammonium chlorides respectively. E. A. Werner and J. Bell. Chem. Soc. Trans., 1922, 121, 1790—1794.

The reaction for the preparation of guanidine salts by heating dicyanodiamide with an ammonium salt (J., 1920, 801 A) has been extended to the preparation of methyl- and dimethyl-guanidine hydrochlorides. Thus, fusion of an intimate mixture of dicyanodiamide and dimethylammonium chloride for 3 hrs. at 180° C., and extraction of the product with alcohol gave a nearly quantitative yield of dimethylguanidine hydrochloride. Methylguanidine hydrochloride prepared in a similar way is a very hygroscopic salt. If the fusion is carried out at lower temperatures considerable quantities of dimethyldiguanide hydrochloride are present in the reaction product. This substance is not to be regarded as an intermediate product of the reaction; it is, on the contrary, produced by a reversible change from guanidine, and the mechanism of the formation of guanidine from dicyanodiamide previously put forward (*loc. cit.*) is still in the authors' opinion the correct one.
—G. F. M.

Piperitone. IV. Interaction of dl-piperitone and semicarbazide, and the isolation of pure dl-piperitone. J. Read and H. G. Smith. Chem. Soc. Trans., 1922, 121, 1863—1872.

A specimen of piperitone prepared by fractional distillation from the oil of *Eucalyptus dives* was converted into the semicarbazone by interaction with semicarbazide hydrochloride (a) in cold aqueous alcoholic solution for 2 days, (b) in cold aqueous alcoholic solution in presence of sodium acetate, and (c) in boiling aqueous alcoholic solution in presence of sodium acetate. From preparation (a) a yield of 36% of the α-semicarbazone, m.p. 226°—227° C., was obtained and a further 34% yield of the more strongly basic β-semicarbazone, m.p. 174°—176° C. on the addition of ammonia to the mother liquor. Preparation (b) gave a mixture of the two semicarbazones, and (c) a 62% yield of the α-semicarbazone and only a very small amount of the β-compound. A semicarbazide-*dl*-piperitone of the constitution $C_9H_{16}:C(OH).NH.NH.CO.NH_2$ was the product of the reaction of *dl*-piperitone and semicarbazide hydrochloride in alkaline medium. This substance forms glistening leaflets, m.p. 186°—187° C., yields a stable hydrochloride, and represents a definite intermediate additive stage in the semicarbazone formation. From the semicarbazones the ketone was regenerated by steam distillation in presence of 20% of oxalic acid. For the preparation of pure *dl*-piperitone by this method a preliminary purification of the fractionation product by means of sodium bisulphite was necessary. A colourless, optically inactive product was then obtained having the following characters:—b.p. 113° C. at 18 mm., sp. gr. at 20°/4° C. 0·9331, $n_D^{20}=1·4845$, mol. refractivity 46·70.—G. F. M.

Isoeugenol; Electrolytic oxidation of ——. A. Lowy and C. M. Moore. Trans. Amer. Electrochem. Soc., 1922, 65—76. [Advance copy.]

Attempts to convert isoeugenol into vanillin by electrolytic oxidation (*cf.* E.P. 1624 of 1895; J., 1896, 49), using both aqueous sodium hydroxide and dilute sulphuric acid in the cathode chamber, failed in all cases to yield more than traces of vanillin, resinous products of indefinite composition being the main products.—L. A. C.

Isoprene; Addition of hydrogen halide to ——. H. Staudinger, W. Kreis, and W. Schilt. Helv. Chim. Acta, 1922, 5, 743—756.

When isoprene combines with 1 mol. of hydrogen bromide, addition takes place at the α and δ positions, with production of dimethylallyl bromide, $(CH_3)_2C{:}CH.CH_2Br$. This condenses readily with sodium malonic ester to form ethyl dimethylallylmalonate from which, by hydrolysis, dimethylallylmalonic acid $(CH_3)_2C{:}CH.CH_2.CH{:}(COOH)_2$ is obtained, m.p. 95·5°—96° C. The halogen of dimethylallyl bromide is exceedingly reactive, and the compound reacts readily with guaiacol forming an ether which on heating isomerises to *p*-dimethylallylguaiacol, an oil, b.p. 140° C. at 10 mm. With magnesium, dimethylallyl bromide reacts to form, as principal product, the hydrocarbon tetramethyldiallyl, $(CH_3)_2C{:}CH.CH_2.CH_2.CH{:}C(CH_3)_2$, b.p. 45°—50° C. at 11 mm. (*Cf.* J.C.S., Nov.)

—E. H. R.

Isoprene dibromide. H. Staudinger, O. Muntwyler, and O. Kupfer. Helv. Chim. Acta, 1922, 5, 756—767.

By the action of bromine on isoprene in carbon bisulphide solution a dibromide is formed having the constitution $CH_2Br.C(CH_3){:}CH.CH_2Br$. When treated with alcoholic sodium methoxide this loses hydrogen bromide forming a mixture of monobromoisoprenes which could not be separated. The monobromoisoprenes and also dibromoisoprene, obtained by removal of 2 mols. of hydrogen bromide from isoprene tetrabromide, gave no rubber-like polymerisation product. (*Cf.* J.C.S., Nov.)

—E. H. R.

Terpin; Melting point of commercial ——. J. M. Clavera. Anal. Fís. Quím., 1922, 20, 243—246.

The melting point of freshly crystallised terpin hydrate, with rapid heating, is 118·2° C. Anhydrous terpin has m.p. 104·7° C. (*Cf.* J.C.S., Nov.)—G. W. R.

Sulphurised hydrocarbons [ichthyol]; Sulphonated derivatives of the naturally occurring ——. C. Pépin and G. Reaubourg. J. Pharm. Chim., 1922, 26, 258—261.

As the therapeutic value of ichthyol is largely dependent on the amount of "sulphidic" sulphur it contains, as distinguished from total sulphur, which comprises in addition sulphonic and sulphatic sulphur, it is desirable that more precise standards should be laid down for commercial ichthyol preparations, and the following are suggested. Colour, brownish red; completely soluble in water, and the solution after evaporation at 100° C. to constant weight should give an extract weighing at least 50% of the weight of the original product. On ignition there should be no residue. After precipitation by albumin and hydrochloric acid, the addition of barium chloride to the filtrate should only produce a slight opalescence, indicating almost complete absence of ammonium sulphate. The sulphidic sulphur, which can only be estimated indirectly by subtracting from the total sulphur the sulphonic plus sulphatic sulphur, should be at least 15% of the dry residue. Lastly the presence of unsaturated compounds should be indicated by decolorisation of bromine water.—G. F. M.

Reaction of amino nitrogen with nitrous acid. Dunn and Schmidt. *See* XXIII.

Patents.

Dialkylaminoalkyl compounds; Manufacture of aliphatic ——. Farbw. vorm. Meister, Lucius, und Brüning. E.P. 167,781, 13.8.21. Conv., 13.8.20.

Aliphatic dialkylaminoalkyl compounds are obtained by the interaction of halogeno-alkyl-dialkylamines and the alkali salts of β-ketonic acids and like compounds of the type $R.CO.CHR_1.X$, where R and R_1 are hydrogen atoms or any other radicles, and X is an electro-negative group. For example, ethyl α-diethylaminoethylacetoacetate

$$CH_3CO.CH{<}\begin{matrix}C_2H_4N(C_2H_5)_2\\CO.OC_2H_5\end{matrix}$$

a colourless strongly alkaline liquid, b.p. 130°—132° C. at 10 mm., is obtained by boiling chloroethyldiethylamine with an alcoholic solution of the sodium compound of ethyl acetoacetate. The same compound can also be obtained by the action of diethylamine on ethyl α-bromoethylacetoacetate. The preparation of the following compounds is also described: diethylaminoethylmalonic diethyl ester, b.p. 145°—150° C. at 10 mm. pressure; ethyl diethylaminoethylcyanoacetate, b.p. 135° C. at 12 mm. pressure; *bis*-diethylaminoethyldiketohexamethylene-diethylcarboxylate, diethylaminoethylacetonediethylcarboxylate, diethylaminoethylcamphorcarboxylic acid methyl ester hydrochloride, m.p. 184°—185° C., and diethylaminoethylacetylacetone, b.p. 137°—139° C. at 20 mm. pressure.

—G. F. M.

Nicotinic acid; Manufacture of dialkylamides of ——. O. Y. Imray. From Society of Chemical Industry in Basle. E.P. 184,625, 7.6.21.

Dialkylamides of nicotinic acid are prepared by treating a halide or ester of the acid with a dialkylamine. *Example.* Nicotinic acid chloride is heated with an equivalent quantity of diethylamine hydrochloride for 2 hrs. at 160° C. The mass is dissolved in water, mixed with concentrated potassium hydroxide solution, and extracted with ether. The ether is distilled off, and the crude diethylamide distilled in a vacuum. It is a yellowish oil, b.p. 280° C., readily soluble in water and organic solvents, and is precipitated from aqueous solution by concentrated alkali hydroxide. The dipropylamide of nicotinic acid is a yellow oil, b.p. 184° C. at 17 mm., and the piperidide a thick oil boiling at 310° C.—G. F. M.

Cyanamide; Method of and apparatus for producing a solution of —— *from calcium cyanamide.* Wargons Aktiebolag, and J. H. Lidholm. E.P. 186,020, 17.5.22. Conv., 1.12.21.

In the ordinary method of preparing a solution of cyanamide by the continuous addition of calcium cyanamide to water or to a dilute solution of calcium cyanamide and treatment with carbon dioxide, the bulk of the solution increases during the operation and the formation of dicyanodiamide may commence in the storage tank before the alkaline liquor passes on to the carbon dioxide treatment. This is avoided by adding the cyanamide to the circulating liquor in a relatively small vessel, whence it passes immediately to the combined pump and agitator in which it is treated with carbon dioxide. After cooling, the solution passes to a large storage tank in which it accumulates.—C. I.

Anæsthetic compound. O. Kamm and E. H. Volwiler. U.S.P. 1,388,573, 23.8.21. Appl., 14.6.20.

Diallylaminoalkyl esters of benzoic acid or its substitution products are prepared by the interaction of benzoyl chloride or its substitution products with a diallylaminoalkyl alcohol. The γ-diallylaminopropyl ester of *p*-aminobenzoic acid is obtained from γ-diallylaminopropyl alcohol (b.p. 215°—217° C. at 755 mm.; prepared by condensing trimethylenechlorhydrin and diallylamine) and forms a hydrochloride of m.p. 138° C. The β-diallylaminoethyl ester of *p*-aminobenzoic acid forms a hydrochloride of m.p. 158°—160° C. The products possess anæsthetic properties.

Hydroxylamines; Salts of aromatic ——. N. Sulzberger. U.S.P. 1,390,260, 6.9.21. Appl., 18.12.18.

An aromatic hydroxylamine is treated with an organic acid. Phenylhydroxylamine oxalate prepared in this way is of value as a photographic developer.

Aromatic aminoalcohols; Process of preparing optically-active ——. A. Gams and E. Wybert, Assrs. to Soc. of Chem. Ind. in Basle. U.S.P. 1,423,101, 18.7.22. Appl., 14.10.21.

Optically-active salts of aminoketones are reduced to the salts of the corresponding optically-active amino-alcohols, and these are subsequently separated from each other and converted into the free bases.—L. A. C.

Urea; Process of manufacturing ——. C. Bosch and W. Meiser, Assrs. to Badische Anilin u. Soda Fabrik. U.S.P. 1,429,483, 19.9.22. Appl., 9.7.20.

A mixture of ammonia and carbon dioxide in suitable proportions is heated under pressure so as to prevent the separation of ammonium salts, and the compressed gaseous mixture is transferred at the same temperature to a reaction vessel, in which the temperature is reduced so as to form a melt, which is kept at a temperature suitable for the production of urea.—J. S. G. T.

Urea; Manufacture of —— from ammonia and carbon dioxide. N. W. Krase. U.S.P. 1,429,953, 26.9.22. Appl., 3.3.21.

Ammonium carbamate is heated to 140°—165° C. under pressure in the presence of an aqueous liquid. (*Cf.* J., 1922, 610 A.)—L. A. C.

Aldehydes and anhydrides; Process of manufacturing —— from di-esters. F. W. Skirrow, Assr. to Shawinigan Laboratories, Ltd. U.S.P. 1,429,650, 19.9.22. Appl., 8.11.20.

An oxide of sulphur is used as a catalytic or decomposing agent in the decomposition of di-esters to form aldehydes and anhydrides.—L. A. C.

Amines; Process of making substituted ——. C. B. Chatfield. U.S.P. 1,429,714, 19.9.22. Appl., 5.3.19.

Substituted amines are prepared by gradual reaction under atmospheric pressure between a bromide of the substituting radicle and the amine in the presence of an alkali hydroxide, which neutralises the hydrogen halide liberated by the reaction.—L. A. C.

Esters; Process of making ——. W. H. Rodebush, Assr. to U.S. Industrial Alcohol Co. U.S.P. 1,430,324, 26.9.22. Appl., 8.5.19.

Esters are prepared by heating a mixture of ethylene dichloride, a salt of a fatty acid, and ethyl alcohol to 160°—180° C. under a pressure of about 150 lb. per sq. in.—L. A. C.

Powdered sulphur; Process for making an exceedingly fine —— incorporated with charred sugar. P. Mochalle. G.P. 355,120, 22.9.20.

An aqueous suspension of "sulphur-sugar" (prepared by heating a mixture of 1 pt. of sulphur and 3 pts. of sugar, and treating the product with 20 times its weight of water) is subjected to the action of a current of air at 40° C. for a long time, whereby the solution becomes acid and gradual decomposition takes place. The charred sugar adheres to the surface of the sulphur particles, which are then separated and dried. The dry sulphur forms a fine, floury, yellowish-grey powder, can easily be suspended in water, and is in consequence better suited for use in medicine and skin therapeutics than the usual sulphur suspensions. —H. C. R.

[*Organic*] *silver compounds; Preparation of complex* ——. F. Hoffman-La Roche und Co. A.-G. G.P. 356,912, 14.12.20. Conv., 1.12.20.

Silver compounds readily soluble in water and of therapeutic value are prepared by heating thioacyl derivatives of aromatic amines with organic or inorganic silver salts. Silver nitrate solution is added, drop by drop, to a solution of thioglycolaminophenol in aqueous sodium hydroxide, and silver thioglycolaminophenol containing 37·2% Ag is precipitated by subsequent addition of alcohol. Thioglycolaminophenol, m.p. 105° C., is prepared by reaction between chloroacetylaminophenol and aqueous sodium disulphide. Chloroacetylaminosalicylic acid, prepared by treating aminosalicylic acid with chloroacetyl chloride, on treatment in alkaline solution with sodium disulphide and subsequent acidification yields thioglycolaminosalicylic acid, m.p. 223° C. The acid is converted into the sodium salt by the action of sodium in alcoholic solution, and is then treated with silver nitrate or acetate, yielding silver thioglycolamino-sodium-salicylate. Similar products, containing 6·1% Ag, are prepared from thioisovaleryl- and thiopropionylaminosalicylic acids. The products in aqueous solution yield no precipitate on the addition of sodium chloride, hydrogen sulphide, or ammonium sulphide.—L. A. C.

Squills (Scilla or Urginea maritima); Process for extracting a therapeutic drug from ——. C. W. Rose and L. Rosenthaler. G.P. 357,043, 14.3.14.

The plant is first extracted with ethyl or methyl alcohol, acetone, or ethyl acetate, the solvent evaporated, and the extract dissolved in an aqueous solution of an alkali carbonate or bicarbonate. The solution is filtered, evaporated to dryness, and the residue again extracted with ethyl or methyl alcohol, acetone, or ethyl acetate, and the solvent removed under vacuum. The residue is soluble in water to a clear solution, and is valuable as a drug in cases of heart failure. It can be taken internally or injected, and is sometimes even more effective than digitalis preparations.—H. C. R.

ar-Tetrahydro-β-naphtholcarboxylic acid and its esters and acyl derivatives; Preparation of ——. Tetralin Ges.m.b.H. G.P. 357,663, 23.5.17.

Potassium ar-tetrahydro-β-naphthoxide, after drying by heating in a current of hydrogen at 150°—160° C., is treated with carbon dioxide under pressure at 160°—170° C. After absorption of 1 mol. of carbon dioxide the product is dissolved in water, and tetrahydro-β-naphthol-*o*-carboxylic acid, m.p. 177°—178° C., after crystallisation from dilute alcohol, is precipitated by the addition of hydrochloric acid. The product can be employed as a drug or as an intermediate in the manufacture of dyestuffs, while its esters and acyl derivatives can be used as solvents and drugs or in the manufacture of perfumes. The methyl ester has b.p. 184°—185° C. at 20 mm., and the acetyl-derivative, prepared by the action of acetic anhydride in the presence of sulphuric acid on the acid at 100° C., melts at 142°—143° C.—L. A. C.

Methylsulphites of secondary aromatic-aliphatic amines; Manufacture of ——. Farbw. vorm. Meister, Lucius, und Brüning. E.P. 164,002, 30.5.21. Conv., 31.5.20.

See U.S.P. 1,426,348 of 1922; J., 1922, 786 A. [Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 16,713 of 1897 and 6991 of 1909.]

Thymol; Manufacture of ——. J. Y. Johnson. From Badische Anilin und Soda Fabrik. E.P. 186,202, 18.7.21.

SEE U.S.P. 1,412,937 of 1922; J., 1922, 438 A.

Alcohol; Process for the production of —— from gas containing ethylene. C. A. Basore. Reissue 15,211, 25.10.21, of U.S.P. 1,385,515, 26.7.21. Appl., 2.9.21.

Solutions containing oxygen. E.P. 185,659. *See* VII.

XXI. — PHOTOGRAPHIC MATERIALS AND PROCESSES.

Silver bromide emulsions; Effect of colloids on ——. R. Schwarz and H. Stock. Z. wiss. Phot., 1922, 22, 26—32.

THE influence of catalysts on the photochemical decomposition of pure silver bromide has been investigated, the amount of decomposition being determined by the method previously described (J., 1921, 791 A). Platinum sol delays the inversion point and solarisation; silver sol and silicic acid sol act as positive catalysts, and aluminium hydroxide as a negative catalyst. Ferric hydroxide and stannic acid coagulated the emulsion.—W. T.

[Potassium] sulphite-quinol [developer]; Ageing and decay of ——. J. Pinnow. Z. wiss. Phot., 1922, 22, 72—80.

A BRIEF review is given of the changes which potassium sulphite-quinol undergoes by the action of the oxygen of the air. Potassium quinolmonosulphonate is a slow and comparatively weak developer. No evidence was obtained of the formation of the sulphonic acid in the sulphite-quinol mixture at room temperatures.—W. T.

Actinometers; Chemistry of ——. A. Benrath and A. Obladen. Z. wiss. Phot., 1922, 22, 47—64.

THE mercuric chloride-ammonium oxalate actinometer was found to be reliable only within narrow limits. The ferric chloride and oxalic acid-uranyl acetate actinometers gave results in good agreement. Electrolytes retard the reduction of ferric chloride and the decomposition of oxalic acid. The authors argue that this is caused by a reduction in the ionisation and that the ferric and oxalate ions are the photochemically active parts.—W. T.

Ultra-violet absorption; Simple method for the measurement of ——. C. Winther, B. Rasmussen, and E. Schreiner. Z. wiss. Phot., 1922, 22, 33—46.

THE photographic method of Merton (Trans. Chem. Soc., 1913, 103, 124) has been adapted for the quantitative measurement of ultra-violet absorption. An improved fluorometer has been constructed for extinction measurements of certain wave lengths and the accuracy of the instrument has been tested by thermo-electric controls.—W. T.

PATENTS.

Colour photography. H. C. J. Deeks, Assr. to American Raylo Corp. •U.S.P. 1,430,059—61, 26.9.22. Appl. (A) 25.6.14, (B) 11.10.16, (C) 17.11.16. Renewed (A) 9.11.20, (B,C) 9.4.21.

(A) A COLOURED photographic print is made by dyeing a film containing a volatile solvent by bringing it into contact with a photographic element bearing a dye insoluble in water but soluble in the volatile solvent. (B) A colour sheet for making coloured photographic positives for transfer by a suitable agent consists of a base carrying a medium which can be sensitised. This medium contains a dye soluble in the agent, and with the dye a protective material also soluble in the agent, but inert to the treatment to which the colour sheet is submitted to prepare it for transfer; so that the pigment resulting from the combined dyestuff and protective material will not affect nor be affected by the treatment, but will yield to the transfer agent. (C) The pigment used in making coloured photographs is a combination of a dyestuff soluble in water and alcohol, together with a material soluble in alcohol but insoluble in water. The pigment will thus retain its colour in aqueous solutions but will give it up in alcohol or alcohol-containing solutions.—W. C.

Printing plates; [Photographic] process for producing ——. E. Albert. U.S.P. 1,430,347, 26.9.22. Appl., 19.5.14.

A PLATE which has an etching ground and overlying sensitive bichromated colloid layer is treated, after exposure, with a solvent, which permeates only the unexposed portions of the coating, removing these portions and their underlying etching grounds, but not affecting the exposed parts of the sensitive film nor the etching ground beneath those parts.—W. C.

[Photographic] coating composition and process. L. D. Wood. U.S.P. 1,430,484, 26.9.22. Appl., 1.7.22.

FOR the reproduction of sound waves which have been photographically recorded, a sensitive compound is used, consisting of 20 pts. of potassium platinum-barium-cyanide crystals, 10 pts. of sodium tungstate, 70 pts. of selenium crystals, 34 pts. of salt, 33 pts. of sulphur, and 33 pts. of phosphorus. It is prepared by melting a mixture of potassium platinum-barium-cyanide crystals, sodium tungstate, and selenium crystals, adding a mixture of salt, sulphur, and phosphorus, heating the molten mass for about 30 mins., or until the flame colour of both barium and potassium rises from the mass, and then crystallising by immersing the mass in water at about 40° F. (4° C.).—W. C.

Films. U.S.P. 1,429,174 and 1,429,179. *See* V.

Salts of aromatic hydroxylamines. U.S.P. 1,390,260. *See* XX.

XXII.—EXPLOSIVES; MATCHES.

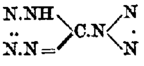
Primers; Microscopy of small arms ——. E. M. Chamot. Pamphlet. Ithaca, New York, 1922. 61 pp.

THE most important causes of the defective functioning of American military primers during the war are enumerated, and photomicrographs of typical primers of this class and also of sections of early primers and cartridge cases are given. The method of manufacture of primers is outlined and the instruments used in their routine microscopical inspection are fully described and illustrated. A binocular dissecting microscope of the Greenough type was used for the inspection of primers, and a comparison eye-piece attached to two chemical microscopes was found useful for comparing different lots of the constituents of primer compositions. The apparatus used for making photomicrographs of primers is also illustrated, as also are all the various tools used in the dissection of primers. Full details are given of methods for removing the primers from the cartridge cases, removing the anvils, and sectioning the primers, which can be accomplished without much risk of igniting them. Many photomicrographs of sectioned primers (chiefly of the loose anvil type) are given, illustrating common defects likely to cause miss-fires. The microscopy of the components of primer compositions is touched on and photomicrographs of samples of the commoner ingredients shown. The defects brought to light by microscopical inspection of primers during the war are analysed. Of these 28·5% were defects in assembly and other mechanical imperfections; 25% poorly compressed or with thick pellets of composition, and 12·6% due to the flame produced not being hot enough. —H. C. R.

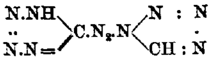
Patents.

Initial primers and a process for their manufacture. H. Rathsburg. E.P. 185,555, 27.6.21.

An initial priming composition for detonators or percussion caps is afforded by one or more explosive salts of tetrazol or triazol compounds or their derivatives mechanically mixed or crystallised with another explosive constituent. The most important salts are those of lead and cadmium. An example of a filling for a blasting detonator is 1 g. of tetryl, 0·15 g. of the lead or cadmium salt of tetrazylazoimide,



and 0·15 g. of the lead salt of azotetrazol,



—H. C. R.

Burning compositions; Binder for ——. Torch fuse-lighter. E.P. Aurand, Assr. to Atlas Powder Co. U.S.P. (A) 1,388,501 and (B) 1,388,502, 23.8.21. Appl., 5.5.21.

Nitrostarch gelatinised with acetone, amyl acetate, butyl acetate, or other solvent, is used as a binder for (A) black powder or other compositions for rockets, flares, signals, etc., or (B) mealed black powder or similar mixtures for fuse-lighters.

Explosive composition and the manufacture thereof. E. M. Werner, Assr. to The Hoynesite Explosives Co. U.S.P. 1,430,272, 26.9.22. Appl., 15.11.21.

A composition which includes in its ingredients an alkali chlorate mixed with a solution of nitrobenzol and resin.—H. C. R.

Explosive; Preparation of an —— from ammonium nitrate and carbonaceous material. Verein Chem. Fabr. in Mannheim. G.P. 346,224, 19.12.16. Addn. to 334,547 (J., 1922, 789 A).

In addition to, or in place of, ammonium nitrate and oxalate and the amino-bases specified in the chief patent, ammonium perchlorate is added to the mixture. The resulting product is safer to handle and more easily detonated.—A. R. P.

Fuse for blasting with liquefied gas and method of producing the same. A. Kowastch. U.S.P. 1,424,487, 1.8.22. Appl., 19.7.20.

See E.P. 148,534 of 1920; J., 1921, 872 A.

XXIII.—ANALYSIS.

Shaking machine for large quantities of fluid [; Laboratory ——]. H. Franzen. Z. physiol. Chem., 1922, **122**, 86—87.

An apparatus is described suitable for stirring up large amounts of lead precipitates in aqueous suspension, whilst treating them with carbon dioxide or hydrogen sulphide.—W. O. K.

Calorimetric determinations. P. E. Verkade. Chem. Weekblad, 1922, **19**, 389—393.

The special benzoic acid obtainable from the *Institut International d'Etalons physico-chimiques*, The University, Rue des Sols, Brussels, should always be used for standardising bombs. The heat of combustion accepted for this material is 6324 cals. per g. weighed in air. (*Cf.* J.C.S., Nov.)—S. I. L.

Ferrocyanide; Influence of the alkalis on the titration of some metals with ——. W. D. Treadwell and D. Chervet. Helv. Chim. Acta., 1922, **5**, 633—639.

The electrometric titration of zinc with potassium ferrocyanide was described by Treadwell and Weiss (J., 1920, 137 A). It is now found that when cadmium or zinc salts are titrated with potassium ferrocyanide in neutral or weakly acid solution, the sharpness of the end point can be greatly increased by having present a small amount of a rubidium or preferably a cæsium salt. The cæsium salt replaces potassium in the precipitate. Thus a zinc salt with potassium ferrocyanide gives $Zn_3K_2[Fe(CN)_6]_2$, but in presence of a cæsium salt the precipitate has the composition $ZnCs_2Fe(CN)_6$. With sodium ferrocyanide in neutral solution the precipitate is the simple zinc salt $Zn_2Fe(CN)_6$. Lead nitrate can be titrated electrometrically with potassium ferrocyanide in neutral solution, but the precipitate, $Pb_2Fe(CN)_6$, is sensitive to acid. Consequently it is possible to titrate zinc in presence of lead in hot acid solution. In presence of a cæsium salt the lead is precipitated by ferrocyanide in the form of the double salt $Pb_3CS_2[Fe(CN)_6]_2$. (*Cf.* J.C.S., Nov.)—E. H. R.

Arsenic; Microchemical detection of ——. A. Piutti and E. Boggio-Lera. Gazz. Chim. Ital., 1922, **52**, II., 48—55.

For the detection of traces of arsenic the most suitable reagent is molybdic acid. With solutions containing 0·02—0·004 mg. of arsenic per c.c. a mixture of 1 c.c. of 3% ammonium molybdate solution, 10 c.c. of 3·4% ammonium nitrate solution, and 39 c.c. of 40% nitric acid (29° B., sp. gr. 1·251) is used, whilst with smaller concentrations of arsenic this mixture is diluted five times with 40% nitric acid. A drop of the arsenical solution is placed on a warm microscope slide, evaporated to one-third of its volume over a very small flame, treated with a drop of the molybdic reagent, and evaporated either on a water-bath or with great care over a small flame. When the drop is diminished to one-half its volume, the slide is tilted, the tilting being gradually increased; the evaporation should occupy at least 6—7 minutes. The cold residue is treated with a drop of a solution containing 5 g. of ammonium nitrate and 4 c.c. of nitric acid per 100 c.c. of water, covered with a cover-glass and examined under a magnification of at least 250 diameters. In presence of arsenic acid the edge of the drop is seen as a thin yellow line composed of characteristic, sulphur-yellow crystals. With practice, 0·001 mg. of arsenic per c.c., that is 0·00005 mg. per drop, is detectable in this way. If animal organs are to be examined, these should be destroyed in the usual way and the arsenic precipitated as sulphide, the latter being purified and then oxidised by means of nitric acid, which must be subsequently eliminated completely.—T. H. P.

Copper, thiocyanates, and pyridine; Sensitive reaction for ——. G. Spacu. Bul. Soc. Stiinte Cluj, 1922, **1**, 284—291. Chem. Zentr., 1922, **93**, IV., 737.

A compound insoluble in water and having the formula $CuPy_2(CNS)_2$ (Py=pyridine) is formed on adding a neutral solution of a thiocyanate and a few drops of pyridine to a neutral solution of a copper salt. The pyridine should be added before the thiocyanate solution, as otherwise a dark precipitate of copper thiocyanate is thrown down in concentrated solutions. In employing the reaction

to detect copper, strongly acid solutions must be evaporated and feebly acid solutions neutralised by the addition of pyridine, care being taken to avoid the addition of excess, as the precipitate is soluble in pyridine. The reaction is sensitive to 1:300,000 as a test for copper, to 1:2000 for pyridine, and 1:50,000 for thiocyanates. The sensitiveness can be increased to 1:800,000 for copper by shaking the mixed solutions with several drops of chloroform, which assumes an emerald green coloration.
—L. A. C.

Chlorides and bromides; Detection of —— in the presence of thiocyanates. G. Spacu. Bul. Soc. Stiinte Cluj, 1922, **1**, 302—305. Chem. Zentr., 1922, **93**, IV., 735.

Pyridine (8-10 drops) and excess of a neutral copper sulphate solution are added to a neutral solution containing thiocyanates, and after separating the precipitate of $CuPy_2(CNS)_2$ (*cf.* preceding abstract), the solution can be tested for chlorides and bromides by the usual methods.—L. A. C.

Phosphoric acid; Separation of —— in qualitative analysis. N. Tarugi. Boll. Chim. Farm., 1922, **61**, 545—552.

Gattermann and Schindhelm's method for the elimination of phosphoric acid by treatment with stannic chloride (J., 1917, 165) is unsatisfactory, since an appreciable proportion of the phosphoric acid remains unprecipitated and the precipitate contains portions of the iron, chromium, calcium, barium, etc. Further, a definite ratio between phosphate and stannic chloride is unattainable when the amount of the former is unknown.—T. H. P.

Radioactive indicators. F. Paneth. Z. angew. Chem., 1922, **35**, 549—552.

Use has been made of radioactive isotopes of metals such as lead and bismuth for indicating the presence of minute and unweighable quantities of these elements or their compounds. Quantities of the radioactive isotopes of the order of a millionth of a milligram are easily detected by the electroscope. Once mixed with the inactive isotope, they cannot be separated by chemical means, so that the presence of the radioactive isotope indicates the presence of the inactive one also. Practical applications have been made in analytical chemistry in determining the solubility of very sparingly soluble substances (*cf.* J., 1913, 866, 1131) and the study of adsorption phenomena. In electrochemistry it has been established by this method that an interchange of metallic ions occurs in solution on mixing two salts of the same metal, but that no such interchange occurs when one or both of the compounds are unionised. The actual deposition of an unweighable quantity of metal on the electrode before the minimum potential of electrolysis is reached has also been established. In colloid chemistry the active surface of powders has been measured for the first time by the use of a radioactive indicator (*cf.* J., 1922, 485 A), and the distinction between crystalloid and colloid in diffusion through parchment membranes has been studied down to a dilution of 10^{-11} g.-mol. per litre. In inorganic chemistry the conditions for the preparation of bismuth and lead hydrides (*cf.* J., 1920, 747 A) were studied by this means and the method was successfully applied to the measurement of the gas-tightness of rubber fabrics for gas masks.
—H. C. R.

Protein precipitants. A. Hiller and D. D. van Slyke. J. Biol. Chem., 1922, **53**, 253—267.

With the object of ascertaining the extent to which proteins and protein products are precipitated by different protein precipitants, the action of a number of these substances both on blood and Witte's peptone has been studied. The results with the latter substance indicate that tungstic acid and picric acid precipitate protein intermediate products relatively completely without precipitating the amino-acids; trichloroacetic acid removes proteins only, nearly all the protein products passing into the filtrate; whilst metaphosphoric acid, colloidal iron, and mercuric chloride occupy an intermediate position with regard to their action on protein products. Using blood, all the substances studied removed proteins completely, and all, with the exception of alcohol, allowed similar amounts of amino-acids to pass into the filtrates. The recovery of added, mixed monoamino-acids was, however, incomplete in the cases of metaphosphoric acid and alcohol.—E. S.

Aliphatic amino nitrogen; Influence of position and of temperature upon the reaction of —— with nitrous acid. M. S. Dunn and C. L. A. Schmidt. J. Biol. Chem., 1922, **53**, 401—410.

The rate at which nitrous acid deaminises aliphatic amino-acids depends on the position of the amino group; the greater the distance of this from the carboxyl the more slowly the reaction proceeds. In all cases a decrease in temperature causes a diminution in the rate, but, contrary to the statement of Sure and Hart (J. Biol. Chem., 1917, **31**, 527) the deamination of the ϵ-amino group of lysine is not completely inhibited at 1° C. Casein is deaminised more slowly than lysine at ordinary temperatures.

Patent List

The dates given in this list are, in the case of Applications for Patents, those of application and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given: they are on sale at 1s. each at the Patent Office, Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, 15 days after the date given.

I.—GENERAL; PLANT; MACHINERY.

Applications.

Eley. Furnaces. 28,665. Oct. 21.

Farbw. vorm. Meister, Lucius, u. Brüning. Apparatus for absorbing gases etc. by charcoal. 27,311. Oct. 9. (Ger., 25.11.21.)

Fothergill. Evaporators. 27,288. Oct. 9.

Grönqvist. 28,039. *See* X.

Holmes. Preparation of a solution. 27,915. Oct. 14.

Lawrence Patent Water Softener and Sterilizer Co., and Stevens. Heating liquids and softening or sterilising water. 28,254. Oct. 18.

Leigh. Crates for acid carboys. 28,255. Oct. 18.

Macconochie. 28,424. *See* II.

Marks (Kohlenscheidungs Ges.). Method of heating at moderate temperatures. 28,082. Oct. 16.

Neil and Neil. Furnaces. 28,443. Oct. 19.

Newby. Separation of moisture from pulverulent, granular, etc. materials. 28,355. Oct. 18.

Pellissier. Pulverisers. 28,199. Oct. 17. (Fr., 27.10.21.)

Petitpierre. Storing gases or inflammable liquids. 27,852. Oct. 13. (Belg., 20.10.21.)

Reynard, Tapping, and Thornley. Clarification and filtration of slimes etc.

Sinkinson. Filter washers. 27,707. Oct. 12.

Technical Research Works, and Lush. Method of activating and re-activating metallic catalysts. 28,600. Oct. 20.

Complete Specifications Accepted.

9356 (1921). Cannon. Furnaces. (186,639.) Oct. 18.

9653 (1921). Ward, Nielsen, and Lang. Treatment of gases, oil vapours, or gaseous mixtures. (186,945.) Oct. 25.

13,564 (1921). Miller and Lloyd. Grinding or crushing machines. (186,956.) Oct. 25.

16,279 (1921). Marshall. Discharging or charging devices for rotary dryers, kilns, furnaces, retorts, etc. (186,974.) Oct. 25.

17,951 (1921) and 3617 (1922). Bleloch and Stockman. *See* X.

18,100 (1921). A.-G. Kummler u. Matter. Preventing corrosion in evaporating and distilling apparatus. (166,129.) Oct. 18.

18,653 (1921). Bologa. Stills. (187,007.) Oct. 25.

22,885 (1921). British Thomson-Houston Co. (General Electric Co.). Chemical apparatus for precipitation purposes. (187,090.) Oct. 25.

29,020 (1921). Mather. Settings for stills etc. (186,849.) Oct. 18.

34,284 (1921). Lilienfeld. Manufacture of colloidally-soluble substances and of suspensions or emulsions. (173,230.) Oct. 25.

34,350 (1921). Maschenenfabr. Haas Ges. Neuwerk. Tunnel dryer with air circulation. (173,234.) Oct. 25.

19,192 (1922). Hall. Centrifugal separators. (183,133.) Oct. 25.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Applications.

Accioly. Apparatus for treating mineral oil. 28,438. Oct. 18.

Appleby and Bentley. Gas-producers, retorts, etc. 27,821. Oct. 13.

Berg (Berg). Gas production. 27,425. Oct. 10.

Carpenter, and South Metropolitan Gas Co. Purification of coal gas. 28,605. Oct. 20.

Cureton and Rowlson. Combined press and retort for the manufacture of coke. 28,167. Oct. 17.

Danner. Emulsified liquified petrolatum. 28,134. Oct. 17.

Grönqvist. Production of incandescent heating conductors. 28,038. Oct. 16.

Johnson and Lucas. Gas-producers. 27,676. Oct. 12.

Macconochie. Dry centrifugal gas-cleaner. 28,424. Oct. 19.

Neath. Manufacture of gas from coal and oil. 28,459. Oct. 19.

Petitpierre. 27,852. *See* I.

Plauson's (Parent Co.), Ltd. (Plauson). Cracking and refining oils. 28,328. Oct. 18.

Reynard, Tapping, and Thornley. Fuel briquettes etc. 27,314. Oct. 9.

Soc. Ricard, Allenet et Cie. Rendering soluble liquid fuel mixtures of petrol and alcohol. 27,800. Oct. 13. (Belg., 28.12.21.)

Spencer. Grids for gas-purifiers. 27,970. Oct. 16.

Wilputte. Coke-oven decarbonisation. 27,273. Oct. 9.

Complete Specifications Accepted.

9653 (1921). Ward and others. *See* I.

10,132 (1921). Biddison. Combustible gas. (162,646.) Oct. 25.

13,174 (1921). Dunstan and Thole. Treatment of petroleum and petroleum distillates. (186,955.) Oct. 25.

17,918 (1921). Clewlow. Apparatus for dewatering and compressing peat. (186,690.) Oct. 18.

18,116 (1921). Hennebutte. Dry distillation process. (165,794.) Oct. 18.

18,405 (1921). Brodsky. Distillation of carbonaceous materials and utilising the gases for heating. (186,724.) Oct. 18.

18,493 (1921). Fuller-Lehigh Co. Manufacture of carburetted water-gas. (171,079.) Oct. 25.

19,289 (1921). Walkey and Bargate. Desulphurising petroleum and similar oil. (186,738.) Oct. 18.

19,537 (1921). Woodall, Duckham, and Jones, Duckham, and Kent. Total gasification of fuel. (186,742.) Oct. 18.

21,597 (1921). Foster. Gasification of coal and other carbonaceous material. (187,076.) Oct. 25.

III.—TAR AND TAR PRODUCTS.

Application.

* Barnard. Manufacture of benzidine. 27,305. Oct. 9.

IV.—COLOURING MATTERS AND DYES.

Applications.

Scottish Dyes, Ltd., Thomas, and Thomson. Colouring-matters. 27,328. Oct. 9.

Scottish Dyes, Ltd., and Thomas. Dyestuffs. 28,596. Oct. 20.

Complete Specifications Accepted.

8516 (1921). Soc. Chem. Industry in Basle, and Straub. Manufacture of chromium compounds of azo dyestuffs. (186,635.) Oct. 18.

32,234 (1921). Imray (Soc. Chem. Industry in Basle). Manufacture of β-thionaphthisatin. (186,859.) Oct. 18.

15,081 (1922). British Dyestuffs Corp., Green, and Saunders. Manufacture of intermediates for the production of colouring-matters. (186,878.) Oct. 18.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Applications.

Clavel. Treatment of cellulose derivatives. 28,457. Oct. 19. (Fr., 27.10.21.)

Plauson's (Parent Co.), Ltd. (Plauson). Production of paper from peat. 28,327. Oct 18.

Riechers and Riechers. Treatment of threads of artificial silk, etc. 28,615. Oct. 20.

Complete Specifications Accepted.

18,497 (1921). Acheson. Graphitised vulcanised fibre and methods in preparing same. (172,924.) Oct. 18.

34,257 (1921). Claessen. Manufacture of elastic flexible sheet material from nitrocellulose. (174,331.) Oct. 25.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Applications.

Broomfield and Russell. Waterproofing. 28,139. Oct. 17.

Johnson (Badische Anilin u. Soda Fabrik). Treatment of cellulose esters for dyeing. 28,691. Oct. 21.

Scholefield, and Yorkshire Dyeware and Chemical Co. Manufacture and use of a colloidal substance for dyeing and scouring animal fibres etc. 27,984. Oct. 16.

COMPLETE SPECIFICATIONS ACCEPTED.

24,573 (1921). Linnemann. Apparatus for treating with liquid fibrous or artificial filamentary materials. (169,695.) Oct. 18.

32,885 (1921). La Fayette. Apparatus for treating yarns with dyes or other liquids. (182,758.) Oct. 25.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

APPLICATIONS.

Brewster. Recovering and concentrating acetic acid from pyroligneous acid. 28,093. Oct. 16. (U.S., 19.10.21.)

Chem. Fabr. in Billwarder, and Hasenclever. Production of chrome-alum. 27,717-8. Oct. 12. (Ger., 12.10.21.)

Hartman. 28,032. *See* XI.

Howles and McDougall. Manufacture of lead arsenate. 27,828. Oct. 13.

Mourgeon. Ammonia manufacture. 27,696. Oct. 12.

Williams. Manufacture of salts derived pyrogeneously from metallic orthophosphates. 28,381. Oct. 18.

COMPLETE SPECIFICATIONS ACCEPTED.

15,428 (1921). Krebitz. *See* XII.

17,514 (1921). Manuf. de Prod. Chim. du Nord Etabl. Kühlmann. Mechanically-operated furnaces for roasting pyrites or like ores. (167,464.) Oct. 18.

18,806 (1921). Schmiedel and Klencke. Production of sulphuric acid. (187,016.) Oct. 25.

19,217 (1921). Holmes and Co., Adam, and Cooper. Manufacture of sulphate of ammonia. (187,035.) Oct. 25.

22,170 (1921). Langheinrich. Purification of graphite. (187,080.) Oct. 25.

27,114 (1921). Woodlands (Pátek). Production of hydrogen peroxide. (186,840.) Oct. 18.

34,281 (1921). Clerc and Nihoul. Manufacture of magnesia from dolomite. (173,502.) Oct. 25.

4610 (1922). Deuts. Gold- u. Silber-Scheideanstalt, and Liebknecht. Production of solutions containing hydrogen peroxide. (186,871.) Oct. 18.

VIII.—GLASS; CERAMICS.

APPLICATION.

Grönqvist. 28,039. *See* X.

COMPLETE SPECIFICATIONS ACCEPTED.

16,048 (1921). Frohman. Refractory material. (186,968.) Oct. 25.

30,884 (1921). Deussing. Production of artificial meerschaum. (172,004.) Oct. 25.

31,099 (1921). Feldenheimer and Plowman. Treatment of clay. (186,855.) Oct. 18.

IX.—BUILDING MATERIALS.

APPLICATION.

Woodroffe. Wood substitute. 28,527. Oct. 20.

COMPLETE SPECIFICATIONS ACCEPTED.

18,844 (1921). Dehn (Studebaker Corp.). Treatment of wood. (187,018.) Oct. 25.

32,671 (1921). Young, and Robertson Co. Fire-resisting asphalt or like hydrocarbonaceous material. (186,861.) Oct. 18.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

APPLICATIONS.

Barron, Halliwell, and Hindley. Hardening surfaces of tools. 28,528. Oct. 20.

Crémer. Apparatus for electrolysis of metals. 28,242. Oct. 17. (Belg., 18.10.21.)

Grönqvist. Production of metallic conducting and, as catalysts, metallic-acting surface layers on refractory stone. 28,039. Oct. 16.

Grönqvist. Production of scale-proof surface layers on metals. 28,040. Oct. 16.

Hanciau. Recovery or extraction of gold, platinum, etc. 27,342. Oct. 9.

Harris. Apparatus for refining or separating metals. 28,370. Oct. 18.

Hennes. Preparation of ores etc. for leaching. 27,452, 27,458-9. Oct. 10.

Keet. Concentrator for ores etc. 28,208. Oct. 17.

McBride. Drying ores, concentrates, etc. 28,250. Oct. 17.

Metals Production, Ltd., and Perkins. Recovery of lead from lead sulphate. 27,608. Oct. 11.

Metals Production, Ltd., Perkins, and Taplin. Leaching copper etc. 27,609. Oct. 11.

Mordey. Electromagnetic separation or concentration of minerals. 28,499. Oct. 19.

Motte. Electric depositing, welding, and cutting. 27,593. Oct. 11. (Belg., 13.1.22.)

Rees. Recovery of metal from dross. 28,046. Oct. 16.

Roper. Foundry cupolas. 27,935. Oct. 14.

Saltrick. Iron and steel alloys. 27,553. Oct. 11.

Saltrick. Alloy steels. 27,554. Oct. 11.

Saltrick. Nickel alloys. 27,555. Oct. 11.

Smidth & Co. Agglomeration of ore etc. 27,934. Oct. 14. (Sweden, 20.10.21.)

Soc. Anon. Cockerill. Furnaces for direct reduction of ores. 28,584. Oct. 20. (Belg., 30.3.22.)

Soc. Anon. Cockerill. Treatment of ores containing iron etc. 28,618. Oct. 20. (Belg., 18.5.22.)

Soc. Ferrosilite. Solder for cast iron. 28,051. Oct. 16. (Fr., 20.4.22.)

Technical Research Works, and Lush. 28,600. *See* I.

COMPLETE SPECIFICATIONS ACCEPTED.

17,514 (1921). Manuf. de Prod. Chim. du Nord. *See* VII.

17,951 (1921) and 3617 (1922). Bleloch and Stockman. Apparatus for crushing or reducing minerals, ores, etc. (186,693.) Oct. 18.

18,263 (1921). Gillott. Alloy iron. (186,962.) Oct. 25.

18,748 (1921). Smith. Treatment and concentration of ores etc. (166,888.) Oct. 25.

20,857 (1921). Vivian. Flotation processes for concentrating ores etc. (186,760.) Oct. 18.

22,884 (1921). British Thomson-Houston Co. (General Electric Co.). Aluminium alloys. (187,089.) Oct. 25.

24,658 (1921). Jones (Soc. Anon. Le Nickel). Manufacture of pure nickel. (187,111.) Oct. 25.

25,545 (1921). Goldschmidt A.-G. Bearing metal alloy. (169,703.) Oct. 18.

34,406 (1921). Westinghouse Lamp Co. Preparation of rare metals. (173,236.) Oct. 25.

XI.—ELECTRO-CHEMISTRY.

APPLICATIONS.

Crémer. 28,242. *See* X.

Dutt and Godfrey. Leclanché batteries. 28,684. Oct. 21.

Hartman. Ozone generators. 28,032. Oct. 16.

Hill. Electric accumulators. 27,575. Oct. 11.

Motte. 27,593. *See* X.

Complete Specification Accepted.

18,363 (1921). Kohlmeyer. Electric storage batteries. (186,987.) Oct. 25.

XII.—FATS; OILS; WAXES.

Applications.

Burrows. Mixing ingredients for manufacture of soap. 27,539. Oct. 11.

Kammermann. Apparatus for extracting oils and greases from vegetable substances. 27,560. Oct. 11. (Belg., 9.8.22.)

Complete Specifications Accepted.

9652 (1921). Schicht A.-G., and Grün. Manufacture of nutritious fats. (160,840.) Oct. 18.

I.—GENERAL; PLANT; MACHINERY.

Evaporation of a liquid into a gas. W. K. Lewis. Chem. and Met. Eng., 1922, **27**, 112—114.

The author, in developing the theory of the evaporation of a liquid into a gas, assumes a long tunnel having non-conducting walls, through which flows unsaturated air at a such a low, constant mass velocity that the heat generated by friction may be neglected. The bottom of the tunnel contains a mat or wick kept constantly wet by water from below. The water is furnished to the wick at every point at a temperature equal to the temperature of the water on the upper surface of the wick at that point Humidification of the air takes place during its passage through the tunnel and if this is sufficiently long a state of equilibrium will be reached between the water and the air. At any point in the tunnel a constant set of conditions exists, namely, what is equivalent to a stationary film of air insulating the water from the main body of air and through which heat is diffused from the air to the water. At the same time water vapour is diffusing in the opposite direction through this film into the air. The heat necessary for evaporation can only be supplied by diffusion from the air. These considerations are expressed mathematically in the following equations: $-dW/Ad\theta=k'(p_w-p)$, $dQ/Ad\theta=h(t-t_w)$, and $dQ=-r_w dW$, whence $(p_w-p)=h(t-t_w)/k'r_w$, where W=wt. of liquid evaporated, A=area of liquid in contact with gas, θ=time, p=partial pressure of vapour, t=temperature, r=latent heat of vaporisation, k'=coefficient of diffusion, h=surface coefficient of conductivity of heat between gas and liquid. If P be the total pressure of vapour and vapour-free gas (*i.e.*, the barometric pressure) and H be the absolute humidity of the gas, then by expressing p in terms of P, and neglecting small quantities a close approximation to the last equation is $(t-t_w)=Kr_w(H_w-H)/h$, where $K=29k'P/18$. In considering the changes in humidity and temperature of the air as it moves along the tunnel, it is pointed out that for any movement of the air from the point under consideration there will be a drop in temperature of say dt and an increase in humidity of dH. The heat given up by the cooling must correspond to the heat of evaporation of the water taken up, that is $-Sdt=r_w dH$, S being the number of heat units necessary to change by one degree the temperature of unit weight of vapour-free gas plus the vapour it contains. If S and t_w are constants integration of this equation gives $H=St/r$ +constant. If the tunnel is sufficiently long saturation will occur at a certain point, and if at this point the temperature and humidity be denoted by t_e and H_e respectively, then insertion of these limits gives $(H_e-H)=S(t-t_e)/r_w$ and for this to be identical with $(H_w-H)=h(t-t_w)/kr_w$, H_e must equal H_w, $t_e=t_w$, and $S=h/k$; *i.e.*, the coefficient of heat transfer divided by the coefficient of vapour diffusion through the gas film is constant and equal to the humid heat of the gas. From the formula $S=h/k$ it is possible to predict the performance of a given apparatus, such as a humidifier, water cooler, gas scrubber, air dryer, or a light oil stripping column, for heat transfer or for diffusion.—S. G. U.

Melting point; Relation of —— to boiling point. R. Lorenz and W. Herz. Z. anorg. Chem., 1922, **122**, 51—60.

The ratio of the absolute melting point to the normal boiling point has been calculated for a large number of elements and compounds (inorganic and organic). The mean of all the results was found to be 0·62.—W. T.

Hardness of solid substances and its relationship to chemical constitution. A. Reis and L. Zimmermann. Z. physik. Chem., 1922, **102**, 298—358.

The hardness and the resistance to erosion (by a fine stream of mercury) of crystalline substances run parallel, but the erosion time (time required to produce a given effect) increases more rapidly than the hardness. The hardness depends on the face examined and on the direction of the scratch. In the case of salts which have lattices maintained by the electrostatic attractions of the ions, the hardness is determined by the charges and the distances between the ions. In compounds which have not a salt-like structure the hardness varies with the strength of the residual affinity of the molecules exerted outwardly. In mixed crystals the hardness is greater than the mean of the components and in some cases it is greater than that of the harder constituent. The hardness of compressed pastilles approaches that of the crystals of the substance. The tendency of a substance to form large crystals is to a certain extent a function of the chemical constitution and is often parallel with the hardness. (*Cf.* J.C.S., Nov.)—J. F. S.

Patents.

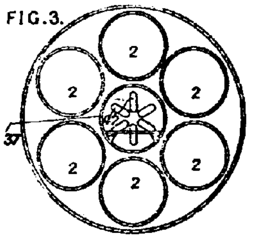
Centrifugal separators; Apparatus for cleaning the bowls of ——. Aktiebolaget Separator. E.P. 181,686, 13.4.22. Conv., 17.6.21.

The bowl is inverted in a tank or vessel and the slime or other adherent dirt removed by jets of steam or pressure water.—B. M. V.

Drying matter containing moisture; Rotary multiple cylinder for ——. J. and S. Buxton. E.P. 185,823, 9.6.21.*

Inside a large cylindrical tube (see fig.), which is mounted on roller bearings and can be rotated by worm gearing, are a number of smaller tubes (drying compartments), 2. Each of these may be fitted with a screw conveyor to move the material from the charging to the discharging end of the plant. Completely surrounding the drying compartments are narrow passages through which flow hot gases or steam. In the case of cylindrical drying tubes these passages may be formed by other tubes, through which air is drawn. In one type of plant steam is blown into the heating passages; the material is fed into the plant at one end and the cold air enters the air tubes at the same end of the plant. Both material and air pass along their respective tubes and are discharged into a chamber at the other end, where the material is removed by a worm conveyor whilst the warm air is drawn back through the drying tubes by means of a fan placed in the chimney,

FIG.3.



---

* The illustrations in the abstracts marked* are reproduced from the Illustrated Official Journal (Patents), by kind permission of the Controller of H.M. Stationery Office.

which is erected at the changing end of the plant. Any moisture formed by the condensation of the steam in the heating passages is automatically removed by a device placed at the lower end of the casing. In another type of plant the front portion of a central tube is used as a furnace, the hot gases from which are delivered at the other end of this tube direct to a chimney. In the portion of this tube between the furnace and the chimney are one or more tubes, 42, providing a means of communication between the atmosphere and the chamber into which the dried material is discharged from the drying compartments. A fan situated at the charging end of the plant and discharging into the chimney draws air through these tubes and causes the hot air to flow as a counter current over the material passing through the drying compartments, 2.—S. G. U.

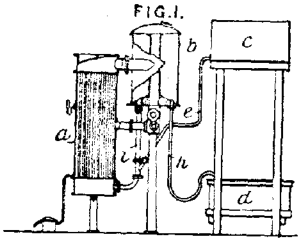
Drying machine. P. J. Shampay. U.S.P. 1,429,976, 26.9.22. Appl., 18.3.20. Renewed 27.2.22.

Round a tube termed the heater element rotates a vertical hollow shaft fitted with blades, forming a fan. This is housed centrally within a cylindrical casing, at the bottom of which is a series of fixed holders to which the goods to be dried are attached at one end. At the upper end of the casing is a horizontal disc capable of being moved along the axis of the casing. The goods to be dried are attached at the other end to the periphery of this disc.—S. G. U.

Evaporators and distilling apparatus. Blair, Campbell and McLean, Ltd., and J. L. Ferguson. E.P. 185,873, 23.6.21.*

A calandria, *a*, of the short vertical tube type, is connected in the usual manner with a separator, *b*. The steam in the separator passes down a vertical internal pipe, which after leaving the separator is fitted with two branches, one connected with the exhaust and the other with a pump, fan, or injector, which compresses a portion of the steam and returns it to the heating space of the calandria. Two outlets are provided at the bottom of the separator. One of these, *h*, is connected either direct or through a heat exchanger with the concentrated liquor tank, *d*. The other, *i*, is coupled to a nozzle placed in the weak liquor inlet pipe, so that some of the hot concentrated liquor can be mixed with the weak liquor entering the calandria. In another type of plant the weak liquor on leaving the heat exchanger mentioned above enters a second heat exchanger placed below the calandria, wherein it is further heated by the condensed steam from the calandria before passing to the mixing nozzle.
—S. G. U.

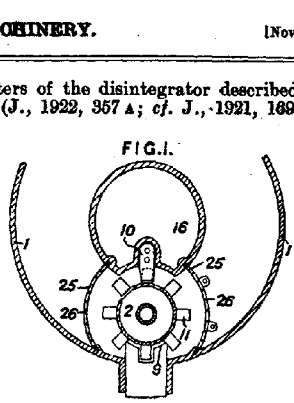
FIG. I.



Disintegrators; High-speed ——. Plauson's (Parent Co.), Ltd. From H. Plauson. E.P. 185,878, 25.6.21.*

By fitting a pair of curved apertured plates, 26, which form part of a cylindrical surface, concentric with the beater shaft, 2, and close up to the tips of the beaters of the disintegrator described in E.P. 176,002 (J., 1922, 357 A; *cf.* J., 1921, 169 A) it has been found possible to diminish the formation of eddy currents and so reduce the power required to drive the mill by about 25%.—S. G. U.

FIG. I.



Grinding or crushing machine. J. W. Spensley. E.P. 186,462, 18.7.21, 23.2.22, and 13.4.22.

In a high-speed centrifugal disc mill or disintegrator with horizontal discs, one fixed, the other rotating, and each provided with intercalating rings of vertical pins, the horizontal discharge takes place substantially all round the circumference, the outlet being obstructed only by the small bosses or pillars necessary to secure the upper portion of the mill; the outer wall of the casing is at such a distance from the discs that sticky substances cannot accumulate sufficiently to obstruct the outlet. The fixed disc is preferably the upper one.—B. M. V.

Liquids; Apparatus for heating or cooling ——. G. L. Lebeau. E.P. 186,218, 5.8.21.

The apparatus consists of two cylinders, one inside the other, with an annular space between. Liquid is passed into the top of the outer cylinder through a pipe connected with a spraying device that distributes it in even films over the inner surface of the outer and the outer surface of the inner cylinder. The inside of the inner and the outside of the outer vessel are heated or cooled by means of a suitable liquid, so that the films of liquid in the annular space between them are rapidly brought to the desired temperature.—A. R. P.

Insulating material against loss or gain of heat. H. Arquint. E.P. 186,492, 17.8.21.

An organic substance which may be used as ropes or plaited work or as powder, is covered or mixed with clay, mortar, or the like, and after application to the article to be insulated is incinerated by heat, by treatment with acids or the like, or electrically.
—B. M. V.

Melting pot. J. B. McClain, Assr. to R. Meier. U.S.P. 1,423,501, 18.7.22. Appl., 25.10.20.

A pot of parabolic formation is provided with a flange for supporting it in a furnace. A horizontal outlet spout is provided at the bottom of the pot and there is a space around the spout for the circulation of heat so that the spout and the wall of the pot above it may be heated. A detachable nozzle can be inserted in the spout, and an internal valve, operated by a wheel above the pot, is provided for closing the nozzle.—T. A. S.

Gaseous mixtures; Apparatus for separation of ——. P. E. Haynes, Assr. to The Linde Air Products Co. U.S.P. 1,429,903, 19.9.22. Appl., 12.4.19.

An apparatus for fractionating gaseous mixtures by a process involving liquefaction of at least a part of the mixture, comprises a gas compressor, an expansion nozzle, a receptacle for collecting liquid issuing from or formed at the expansion nozzle, and a heater for the receptacle. The heater is connected with the compressor and with the expansion nozzle by conduits, in each of which is a cooler, both of these coolers being refrigerated by gases which have passed the expansion nozzle.

Filter. J. S. Kleithline. U.S.P. 1,430,234, 26.9.22. Appl., 18.8.21.

Inside a cylindrical shell having removable ends is placed a second perforated cylindrical shell having only one end removable. The cylinders are fixed together at the mid points of their lengths in such a manner that a liquid in passing from one end to the other of the outer shell must flow through the perforated cylinder, which is filled with a filtering material. An inlet valve is provided at one end of the outer shell and an outlet valve at the other. —S. G. U.

Fire-extinguishing composition. E. A. Louder, Assr. to Boyce and Veeder. U.S.P. 1,430,745, 3.10.22. Appl., 20.11.19.

The composition consists of carbon tetrachloride mixed with about 10% of carbon bisulphide. —B. M. V.

Crystals; Apparatus for the production of ——. C. C. Haferkamp, Assr. to The Diamond Match Co. U.S.P. 1,430,900, 3.10.22. Appl., 28.10.20.

An apparatus for producing crystals from hot liquors consists of a number of superposed, spaced annular units encircling a shaft capable of rotation. Two sets of vanes are mounted on the shaft, those of one set rotating in the spaces between the external flat surfaces of adjacent units, and those of he other set within the circular openings of the units. A cooling agent is circulated through the units.—A. J. H.

Furnaces; Rabble stones for mechanical roasting and calcining ——. Rheinisch-Nassauische Bergwerks- und Hütten-A.-G., W. Hocks, and G. Stohn. E.P. 178,059, 6.7.21. Conv., 7.4.21. Addn. to 163,023.

Furnaces. H. B. Cannon. E.P. 186,639, 29.3.21.

See U.S.P. 1,371,774 of 1921; J., 1921, 288 a.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Stone dusting of [coal] mines. (Part II.) F. S. Sinnatt, A. McCulloch, and J. R. Lomax. Lancs. and Cheshire Coal Research Assoc., Bull. 11, 1922, 27 pages and 3 plates.

The tendency of a coal dust to explode is proportional to the fineness of division of the dust. Thus a coal dust of 1/100 to 1/150-mesh ignited at 1350° C., whilst the same coal ground to pass through a 220-mesh sieve ignited at 850° C. The sensitiveness to inflammation is also inversely proportional to the percentage of volatile organic matter present in the coal, and there is a gradual transition from lignite to anthracite in this respect. The current required to ignite a sample of raw coal (1/200-mesh) was 11·5 ampères, whilst to ignite the pyridine extract a current of only 10·5 ampères was required, as contrasted with 15·0 ampères for the residue from the extraction. It is a fallacy to believe that carbonate minerals such as limestone possess a greater effect in preventing explosions than other minerals of the nature of shale on account of their carbon dioxide content. The temperature at which the carbon dioxide is given off is too high for this action to take place sufficiently rapidly. The presence of moisture tends to prevent explosions of dusts, and experiments carried out in America have proved that the presence of 30% of water in any bituminous coal dust renders it practically non-explosive. It is, however, very difficult thoroughly to wet fusain, which may constitute 20—50% of mine dusts. Fusain and ash have a retarding action on the liability of coal dust to explode. A quantity of 3 oz. of coal dust per cubic yard of air space is sufficient to cause a dust explosion. The least percentage of inert matter in mixtures with coal which will inhibit explosions is given as follows: for boiler ashes, 57; quicklime, 50; ground shale, 43; Chance mud, 38—40; gypsum, 33—35; magnesia, 28—30; anhydrous sodium carbonate, 12—13; soda crystals ($5H_2O$), 10; sodium bicarbonate, 9—10; and Glauber salts, 8. Fine grinding of the inert material produces the most effective results as regards retarding explosions. The analyses of seven shales are quoted, together with photomicrographs of inferior shale, mudstone, dust from inferior shale, shale suitable for stone dust, and dust prepared from the latter shale. Results (unpublished) obtained by Sinnatt and Grounds on the weathering of shale are also quoted, in which it is shown that weathering facilitates the grinding of shale, and that artificial weathering, *i.e.*, alternate heating and cooling, accelerates the breaking down of the shale to a greater degree than natural weathering.—A. G.

Spontaneous combustion of coals and lignites. E. Erdmann. Brennstoff-Chem., 1922, 3, 257—262, 278—283, 293—299.

A historical survey of the subject is given. An attempt to test the liability to spontaneous combustion by treatment with ozonised air was unsuccessful. An apparatus was devised to measure relative initial combustion temperatures (*cf.* Dennstedt and Schaper, J., 1913, 11). The sample (2—4 g.), in which was inserted the bulb of a thermometer, was placed in a glass vessel immersed in an oil bath, and a current of air or oxygen preheated to the same temperature was passed through the sample. The bath was gradually heated until the temperature of the coal began to exceed that of the bath. The lowest (constant) temperature at which the coal must be heated in order that, when subjected to the action of a current of air or oxygen, it should heat up ultimately to inflammation was taken as the initial ignition temperature. Various factors governing spontaneous combustion of brown coals were studied by tests in this apparatus. Increase in concentration of ozone and oxygen accelerated the ignition of the specimen. The inflammability was considerably increased when the size of the grains was diminished. When the moisture content of a coal was increased, its inflammability decreased. Wetting may, however, promote ignition in practice by removing the carbon dioxide which has collected in a pile and facilitating fresh access of oxygen. Weathering was shown to diminish the tendency to ignition, especially of finely divided brown coal, which after 8 days would no longer ignite in cold ozonised oxygen, while the ignition temperature in oxygen was also raised. This effect of weathering is in contrast to that found by Dennstedt and Schaper. The inflammability was also reduced by maintaining the coal for some time a little below its ignition temperature. The inflammability of various lignites and vegetable products was studied to identify, if possible, the active component. No connexion with the percentage of carbon, hydrogen, or oxygen could be traced. It is a question rather of the kind of grouping. Unsaturated compounds are a doubtful cause; polyhydric phenols are more probable active ingredients. The residue, after extraction of bitumen from lignites, is exceedingly prone to ignition. The practical conclusions arrived at are that excess of air and external sources of heat should be avoided, while provision of means of conducting heat away from storage heaps is beneficial. Wetting is not helpful, but a covering of wet fine coal which seals off the air is beneficial. Carbon dioxide and flue gases may also be used for excluding air. The application of these ideas to lignite briquettes is considered.—H. J. H.

Sulphur compounds of coal, their behaviour on distillation, and the sulphur compounds of coke. J. P. Wibaut. Brennstoff-Chem., 1922, **3**, 273—278. (*Cf.* J., 1922, 13 A, 281 A.)

The work of the author and others on this subject is critically reviewed. A method has been elaborated for distinguishing between pyritic sulphur and organic sulphur in coal and coke. When coal containing both mineral and organic sulphur was carbonised, the former was diminished, while the organic sulphur content increased. The carbon apparently fixed some of the sulphur given up by heated pyrites. The formation of carbon sulphides was confirmed by synthetic experiments starting from sugar charcoal and sulphur, and they are regarded as similar to the " physico-chemical complexes " of carbon and oxygen visualised by Rhead and Wheeler (*cf.* J., 1913, 276) in their study of the absorption of oxygen by carbon. The compounds are thermally very stable, and it seems improbable therefore that coke can be desulphurised on a manufacturing scale.—H. J. H.

Lignite; Gasification of ——. E. Dubois and G. Müller. Z. Ver. Deuts. Ing., 1922, **66**, 821—824. Chem. Zentr., 1922, **93**, IV., 854—855.

The high water content of lignite causes difficulties in using it in gas-producers, and it is necessary to dry it before use. In carrying out the drying care must be taken not to reduce the lignite to powder as its subsequent behaviour in the producer is influenced by the size of the lumps, and for this reason they must be subjected to as little movement as possible. High temperatures cannot be employed, and hence a large heating surface is necessary to secure efficient drying; this is best obtained by leading a warm mixture of gases directly through the mass of lignite. A lignite dryer and gas-producer plant designed on these lines and the results obtained with it are described. The lignite used gave the following results on analysis:—Water, 58·7%; ash, 2·23%; carbon, 24·4%; hydrogen, 1·92%; nitrogen, 0·25%; oxygen, 12·2%; sulphur, 0·28%; calorific value, 1945—2400 cals.; tar, 2·05%. The efficiency of gasification was 73·9%, or, with tar recovery, 76·7%. The efficiency of the whole plant, deducting the heat equivalent of the power consumed, was 68·7%.—H. C. R.

Methane; Use of —— in steel cylinders as a fuel and starting-gas for internal combustion engines. J. Bronn. Autotechn., 1922, **11**, 6—8. Chem. Zentr., 1922, **93**, IV., 855.

The chief advantages to be obtained in using methane as a motor fuel are that it is always ready for use even in the most severe cold weather, as it remains gaseous even at the pressure (150 atm.) of the steel cylinders, and its cheapness. Near where it is produced it is 6—7 times cheaper to use than petrol or benzol, and it can be obtained in sufficient quantity, since one ton of coal gives 55 cub. m. of methane as against 8 kg. of benzol, and 1 cub. m. of methane is the equivalent of 4·5 kg. of benzol.
—H. C. R.

Gas engines; Gas requirements of, and composition of exhaust gases from, large ——. D. Rauert. Stahl u. Eisen, 1922, **42**, 1545—1553.

The efficiencies of two-stroke and four-stroke cycle gas engines are compared with reference to the loss of fuel in the exhaust gases. The importance of correct sampling of the exhaust gases so as to prevent any admixture with the external atmosphere, sucked back into the exhaust tube, is emphasised. The loss of fuel in the exhaust gases with the two-stroke cycle is mainly due to inefficient scavenging of the cylinder. The percentage loss decreases with increasing load until the latter is about 75% of the full load, though the absolute loss remains approximately constant. With the gas engines examined the loss under a 75% load was about 10%, but this increased as the load was further increased until as much as 30% was lost when the engine was operating on a slight overload. The loss due to incomplete combustion during the working stroke decreases continuously as the load increases, varying from 30% at quarter load to 1 or 2% at full load. Only the latter loss is operative with four-stroke engines which are in consequence more efficient from this point of view.—W. P.

Paraffin wax; Oxidation of ——. H. Siebeneck. Petroleum, 1922, **18**, 1193—1196.

A paraffin wax from lignite producer tar, of m.p. 54° C., was exposed to the action of oxygen for a period of 55 hrs., as described previously (J., 1922, 282 A). The paraffin wax used (150 g.) contained no acids or esters, and its saponification value was *nil*. Its ultimate analysis was 85·23% C, 14·62% H, and 0·15% O. The temperature of the experiment was 135° C. Products of cracking were found early in the experiment. The absorption of oxygen after 12 hrs. was 9·39%, the acid value of the product 6·19 and the ester value 16·64. After the 12th hour carbon dioxide was evolved, the oxygen content fell to 2·94%, the acid value was doubled, and the ester value and the saponification value increased. After 33 hrs. the ester value fell, the acid value increased, while the saponification value remained approximately constant at about 102. At the conclusion of the experiment the ester value had fallen to 49·16 and the acid value had again risen a little. The rapidity of the reaction diminished towards the close of the experiment owing to the increase in the viscosity of the material to five times the original value. The products of oxidation most likely to find commercial use are the wax-like substances formed in the second phase of the process, between 12 hrs. and 33 hrs.—H. M.

Patents.

Coal; Treatment of —— [by flotation]. F. G. Price, and Minerals Separation, Ltd. E.P. 186,143, 20.6.21.

In the froth-flotation treatment of coal, the addition of various substances aids the separation of the constituents of bituminous coal. Starch solutions, tannic acid, gelatin, glue, albumins, caramel, and dextrin inhibit the flotation of fusain, which may thus be separated from clarain and vitrain. The use of starch is preferred and many varieties have been found to be efficacious. A solution containing 2% of starch and 2% of caustic soda may be used, not more than ¼ lb. of starch being necessary per ton of coal. Good results have also been obtained with ½ lb. of glue, 1 lb. of tannic acid, or ¼ lb. of egg albumin per ton of coal. Ordinary frothing agents, such as cresol, may be added, but may not always be necessary. In treating dirty coals it is advisable to carry out a preliminary concentration to remove ash and shale. A large-scale test was carried out on dross, which gave an exceedingly friable coke useless for metallurgical purposes. The dross contained 21·5% of ash, 26·0% of volatile matter, and 47·0% of fixed carbon. 120 tons of the dross was treated by flotation, the reagents used being 0·4 lb. of cresol, 0·6 lb. of paraffin oil, and 0·25 lb. of starch per ton. The concentrates weighed 80 tons and contained 6·2% of ash, 26·6% of volatile matter, and 53·2% of carbon, and were substantially free from fusain. On coking, an excellent metallurgical coke was produced.—W. P.

Smokeless fuels and coke; Production of ——. S. R. Illingworth. E.P. 186,085, 24.3.21.

Smokeless fuel is manufactured by blending two coals, so that the mixture has a content of resinic matter (soluble in boiling phenol or boiling pyridine and also in chloroform) not less than 5% but preferably not less than 8% of its weight. The mixture is heated to a temperature not exceeding 500° C., or to a temperature 50°—100° above the minimum temperature at which the resinic matter in the blend is destroyed. Coal may be blended with coke, semi-coke, or an ore such as iron ore. The smokeless fuels produced may be further carbonised and converted into a true coke.—W. P.

Peat or similar fuel; Utilisation of surplus power from hydro-electric plant for the preparation of ——. N. Testrup, and Techno-Chemical Laboratories, Ltd. E.P. 186,137, 20.6.21.

The peat is made into a paste on preheating rollers and then dried in a thin uniform film on heated drums. Vapours given off are compressed and heated and passed into the drums to be used as the heating medium. Surplus electric power is used for compressing the vapour, and peat fuel appliances are installed for use when this surplus power is not available.—W. P.

Gas producers. W. Climie. E.P. 186,262, 15.6.21.

The producer consists of two concentric casings separated by a water and steam space, to which are connected headers, adjacent to the producer, these headers being also connected with each other by means of pipes, surrounded by casings. On leaving the producer, the gas is passed through these casings (and if necessary through other similar tubes or passages), the walls of which are swept by brushes in order to filter out suspended matter from the gas. The brush sweepings are discharged through a valve-controlled outlet.—A. G.

Gas-producing apparatus. W. E. Elliott. U.S.P. 1,430,633, 3.10.22. Appl., 17.1.20.

A retort is situated lengthwise above a number of coal-burning compartments, and means are provided for conducting the gases from the compartments to one end of the retort, for introducing air at certain points inside the retort, and for retarding the passage of gas therethrough. A suction pipe communicates with the retort.—A. R. M.

Gas purification. H. F. Smith, Assr. to Gas Research Co. U.S.P. 1,430,696, 3.10.22. Appl., 9.11.18.

Sulphur dust is eliminated from gas generated in a producer using anthracite or similar fuel, by spraying water into the gas before it passes out of the generating chamber.—A. R. M.

Exhaust gases of internal combustion engines; Utilisation of the ——. A. Scherhag. E.P. 167,155, 17.6.21. Conv., 28.7.20.

The exhaust gases are taken up by a centrifugal fan at a point near the outlet of the engine and are mixed with fresh air (up to 400 times the volume of the combustion gases). The fan produces a separation of oily and sooty matter, and the hot mixture is used for the production of hot water supplies, air heating, evaporation or other industrial purpose. The temperature of the mixture is regulated solely by the amount of fresh air sucked into the system. For the purpose of evaporation or for heating water the exhaust gases are blown directly through the liquid, whilst for heating rooms or drying chambers the hot gas is blown directly into the room or chamber.—A. G.

Oily pastes or emulsions [*lubricants*] *from mineral and other oils; Manufacture of* ——. Plauson's (Parent Co.), Ltd. From H. Plauson. E.P. 185,779, 6.4.21.

Emulsions of oil and water are prepared with the aid of a colloid mill (E.P. 155,836; J., 1922, 357 A). These emulsions are of pasty nature and can be used in the same way as Stauffer fat. The water content can be increased to 4 to 8 times that of the oil if 1—3% of a finely powdered solid, *e.g.*, magnesium or barium carbonate or oxide, be added. Graphite or talc or other solid lubricants can be incorporated. If it is desired to incorporate a large amount of water, as for making boring pastes and soap-like lubricants, suitable protective colloids or agents as paraffin wax, glycerin, etc. can be used. The advantage of the process consists in the fact that all the materials used are neutral.—T. A. S.

Hydrocarbon oils and other oils and fats; Process of increasing the consistency of ——. H. M. Frentrup and P. Kiederich. E.P. 185,782, 12.4.21.

A salve-like mass is made from pale spindle oil by adding to it castor oil and fish oil which have been partially hydrolysed by means of sulpho-aromatic acid. The hydrolysis of the vegetable and animal oil must not be carried beyond 50%. A salve melting at 72° C. is made by adding 100 kg. of pale spindle oil (sp. gr. 0·890—0·910) to 5·75 kg. of castor oil which has been partially hydrolysed by Twitchell reagent and to which 1·75 kg. of fish oil has been added. To the mixture 8 kg. of caustic lye (40%) is added and the mass stirred with a spatula.
—T. A. S.

Petroleum oil; Process of treating [*cracking*] ——. R. Cross, Assr. to Gasoline Products Co. U.S.P. 1,423,500, 18.7.22. Appl., 2.5.21.

Oil is heated to cracking temperature by passing it through a tube heated in a furnace. After leaving the tube the oil is maintained at cracking temperature, under the pressure of the evolved gases, in an insulated "reacting chamber." The process is continuous, oil and gas being continuously removed from the reacting chamber. Cracking takes place in the liquid phase.—T. A. S.

Oils; Apparatus for cracking ——. W. B. D. Penniman. U.S.P. (A) 1,429,622 and (B) 1,429,623, 19.9.22. Appl., 25.4. and 5.5.17.

(A) Stills in series are internally heated by means of a hot fluid, the fluid supply being thermostatically controlled. Oil is passed through the system in the opposite direction to the flow of heating fluid. (B) Oil is heated in a still by means of a steam coil. The vapours from the still pass through two chambers containing steam coils. The supply of steam to the various parts of the apparatus is thermostatically controlled.—T. A. S.

Hydrocarbons; Process for the constructive conversion of ——. H. R. Berry. U.S.P. 1,429,910, 19.9.22. Appl., 10.8.22.

Heated gas containing hydrogen and carrying hydrocarbon vapours is caused to flow in counter current to films of relatively cool oil. The pressure and temperature are so controlled that lower-boiling hydrocarbons are produced without the formation of carbon deposits.—T. A. S.

Hydrocarbons; Process and apparatus for producing lighter hydrocarbons from heavier ——. C. V. Woegerer, Assr. to J. R. and W. H. Clarke. U.S.P. 1,429,992, 26.9.22. Appl., 8.5.20.

Hydrocarbons are cracked by atomising them with water and lime and then with steam under pressure and at a temperature below 500° F. (260° C.). They are then allowed to settle under pressure to allow unconverted oil and lime to separate, and finally condensed under pressure.—T. A. S.

[*Paraffin*] *wax-sweating apparatus.* C. S. Dickens, T. E. Schley, and J. W. Newton, Assrs. to Magnolia Petroleum Co. U.S.P. 1,429,721, 19.9.22. Appl., 13.11.20.

WAX is carried by an endless foraminous belt through a series of chambers heated to sweating temperature. Each chamber may be heated to any desired temperature.—T. A. S.

Hydrocarbon; Method of separating —— from aluminium chloride. E. V. Owen, Assr. to The Hoover Co. U.S.P. 1,430,109, 26.9.22. Appl., 21.1.22.

MATERIAL containing aluminium chloride and hydrocarbon is delivered to a bath of liquid material maintained at a temperature sufficiently high to vaporise the aluminium chloride but not the hydrocarbon. —T. A. S.

Dehydrator; Central circulating —— for petroleum oils. Stratifying dehydrator. W. Meredith, Assr. to Petroleum Rectifying Co. U.S.P. (A) 1,430,245 and (B) 1,430,246, 26.9.22. Appl., 14.3. and 30.4.21.

(A) A HOLLOW cylindrical electrode is disposed centrally in a cylindrical container which is also an electrode. Means are provided to cause emulsion to enter the bottom of the inner electrode and pass outwards over the top into the space between the electrodes. A potential difference is maintained between the electrodes. (B) A charged electrode is supported in and surrounded by the emulsion to be treated. Means are provided for surrounding the electrode with a fluid envelope of higher dielectric strength than the emulsion to be treated.—T. A. S.

Dehydrator [*for petroleum emulsions*]. *Adjustable field dehydrator. Double field dehydrator.* (A) H. C. Eddy and J. T. Worthington, (B, C) H. C. Eddy, Assrs. to Petroleum Rectifying Co. U.S.P. (A) 1,430,294, (B) 1,430,295, and (C) 1,430,296, 26.9.22. Appl., (A) 2.3.21, (B, C) 25.6.21.

(A) EMULSIONS are treated in a tank fitted with a cylindrical electrode concentric with the tank, and means are provided for imparting a rotary movement to the body of emulsion. (B) A flat electrode moving in its own plane is suspended in a tank which is also an electrode. (C) A hollow electrode is suspended centrally in a tank which is also an electrode and has a member projecting centrally into the inner hollow electrode.—T. A. S.

Electrical dehydrators [*for petroleum emulsions*]; *Starter for ——. Method of automatic dehydration.* F. W. Harris, Assr. to Petroleum Rectifying Co. U.S.P. (A) 1,430,301 and (B) 1,430,302, 26.9.22. Appl., 1.11.20 and 31.5.21.

(A) AN emulsion is drawn from a bulk supply and passed through an electric field at such a rate that a permanent short circuit in the field is prevented. The coarse emulsion so formed is then submitted to the action of a second electric field in which the disruption of the current paths occurs automatically without mechanical agitation. (B) The dehydrator consists of a tank fitted with electrodes and means for closing the oil inlet valve to the tank on failure of the current supply.—T. A. S.

Fuel briquettes; Artificial ——. W. W. Strafford. U.S.P. 1,430,767, 3.10.22. Appl., 11.4.22.

PATENTS.

Low-temperature tar and semi-coke; Production of —— by distilling bituminous material, such as coal or lignite. Deutsche Erdöl-A.-G. G.P. 356,591, 7.2.19.

THE mixture of steam, gas, and tar obtained by passing a mixture of superheated steam and coal gas over coal, lignite, or the like, is cooled to a temperature sufficiently low to condense the tar, but high enough to prevent condensation of the steam. The residual gases are raised to their original temperature, and again circulated through the distillation apparatus.—L. A. C.

Coal, shale, and other bituminous material; Process for distilling ——. K. Prinz zu Löwenstein, A. Irinyi, and T. Kayser. G.P. 356,820, 4.8.20.

IN distilling bituminous material in apparatus provided with an internally heated screw-conveyor, the adhesion of the material to the conveyor is prevented by scrapers moving up and down independently of one another, the supports for the scrapers being in a chamber, situated on the upper side of the conveyor, in which the products of distillation are collected.—L. A. C.

[*Gas-filled*] *electric incandescence lamps* [; *Preventing blackening of the bulbs of ——*]. N. V. Philips' Gloeilampenfabrieken. E.P. 168,598, 27.8.21. Conv., 2.9.20.

BLACKENING of the bulbs of gas-filled electric incandescence lamps, having a filament not less than 0·1 mm. in diam., is prevented by placing a substance capable of generating a small amount of oxygen during the operation of the lamp, more especially an alkali nitrate or nitrite, on the small plate of mica customarily employed in these lamps. The quantity of oxygen generated must be just sufficient for the oxidation of the tungsten sputtered from the filament. A small quantity of phosphorus may likewise be present in the lamp. [Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 102,141; J., 1917, 1000.]—J. S. G. T.

Tungsten; Manufacture of —— [for lamp filaments]. The General Electric Co., Ltd., and C. J. Smithells. E.P. 186,497, 23.8.21.

Tungstic acid is mixed with a substance which will introduce into the resulting metal an oxide (*e.g.*, thoria) that is not reduced by hydrogen, and with a compound of an alkali metal, the proportions of each being so adjusted that the tungsten oxide before reduction contains 1—0·5% of thoria and 0·3—0·03% of sodium chloride or 0·5—0·05% of cæsium chloride. The resulting filament when burnt in the form of a closely wound spiral in an inert gas develops crystals of tungsten that extend for several coils, thereby increasing the strength of the filament.—A. R. P.

III.—TAR AND TAR PRODUCTS.

Benzene from phenols; Experimental plant for producing ——. F. Fischer, H. Schrader, and K. Zerbe. Brennstoff-Chem., 1922, 3, 289—292.

The apparatus was constructed to study on a larger scale the reduction of phenols by hydrogen to benzene and homologues (*cf.* J., 1920, 511 A, 740 A). The gas was saturated with vapour in passing through a vessel containing heated phenols and thence passed into an iron tube coated internally with tin. This tube was 3 m. long, 28 cm. diam., and could be heated in a special gas furnace to 800° C. The gas and vapour leaving the tube traversed two condensers cooled by water and a freezing mixture respectively and afterwards two vessels charged with activated carbon. The gas was metered before and after passing the apparatus, which was capable of dealing with 12 kg. of phenol per hour. The volatile reaction products were recovered from the carbon by a current of superheated steam. The results obtained are to be published separately.
—H. J. H.

Phenol; Action of sodium carbonate in promoting the hydrogenation of ——. Catalytic action at solid surfaces. E. F. Armstrong and T. P. Hilditch. Proc. Roy. Soc., 1922, A 102, 21—27.

Treatment of phenol at 180° C. with hydrogen under a pressure of 80 lb. per sq. in., in the presence of finely-powdered nickel and sodium carbonate gives a yield of 95% of cyclohexanol and some cyclohexanone. Sodium carbonate has an accelerating action on the change, which is dependent on the amount present, until an optimum quantity is reached amounting to about 25% of the weight of nickel used; an excess above the optimum retards the hydrogenation. This optimum quantity depends only on the relationship with the nickel catalyst. It is suggested that the stimulation of the reaction by sodium carbonate is not a true catalysis but the restoration of the nickel to its normal function by the suppression of a retardation which is probably of the nature of a poisoning of the nickel catalyst by the phenol.—J. F. S.

Nitration of hydrocarbons [anthracene and naphthalene] in a basic or neutral medium. M. Battegay and P. Brandt. Bull. Soc. Chim., 1922, 31, 910—915.

A mixture of 25 g. of pyridine and 100 c.c. of nitrobenzene is treated with 12 g. of nitric acid (sp. gr. 1·52) which has been freed from nitrous acid, the whole being cooled in ice. To this mixture 20 g. of finely divided anthracene is added and nitration is effected by heating to 125° C. for 4—5 hrs. The product is poured into 500 c.c. of water, which should remain neutral. After addition of alkali the pyridine and nitrobenzene are removed by steam-distillation, the liquid is filtered, and the residue freed from alkali by washing, then dried, and extracted with alcohol. On evaporation of the alcoholic extract, 9-nitroanthracene crystallises and is purified by recrystallisation. The filtrate contains nitroanthrone,

$$C_6H_4\left<\begin{matrix}CO\\CH(NO_2)\end{matrix}\right>C_6H_4$$

The nitration of naphthalene may be effected in a somewhat similar manner, zinc chloride being used as a dehydrating agent, with production of α-nitronaphthalene and also of nitrophthalic acid.
—H. J. E.

Patent.

Naphthalene; Process of purifying ——. D. F. Gould, Assr. to Barrett Co. U.S.P. 1,431,394, 10.10.22. Appl., 15.12.20.

See E.P. 172,937 of 1921; J., 1922, 662 A.

IV.—COLOURING MATTERS AND DYES.

Dyestuffs; Methods of determining the fastness of ——. B. Setlik. Chim. et Ind., 1922, 8, 541—543.

A résumé of the tests which are necessary and the methods to be followed in order to obtain a correct estimate of the fastness of a dyestuff under the conditions to which it is likely to be subjected. According to the material on which the dyestuff is used and the purpose for which the article is to be used, tests must be made (a) for wool, for fastness to light, to acids, to water, to washing, to fulling, to sulphur dioxide, to friction, to ironing, to hot water, to perspiration, and to mud and dust; (b) for cotton, for fastness to light and air, to washing, to chlorine and peroxides, to perspiration, to mercerisation, to ironing, and to dressing; (c) for silk goods, for fastness to light, water, washing, perspiration, and mud and dust. To test fastness to light, bands or skeins of material dyed different shades with the same dyestuff are exposed to sunlight with free access of air on both sides, one half being protected for comparison. Fastness to acid is tested by impregnating the material, alone or plaited with white material, with sulphuric acid of 5° B. (sp. gr. 1·036), drying at 80° C., rinsing with dilute soda and water and again drying; fastness to water by soaking for 3 hrs., or boiling for 10 mins., preferably in contact with white material; to washing by warming for ½ hr. in a solution of 10 g. of neutral soap and 1 g. of soda per litre; to perspiration by warming for 24 hrs. at 40° C., steeping in 5% acetic acid several times during this period, and wringing out the excess of acid each time before replacing in the warm water. Mud and dust are often alkaline, and their effect is simulated by making a splash on the material with milk of lime, drying, and brushing off.—G. F. M.

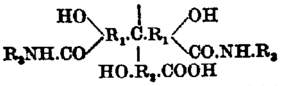
Sugar charcoal; Adsorption [of Methylene Blue] by activated ——. F. E. Bartell and E. J. Miller. J. Amer. Chem. Soc., 1922, 44, 1866—1880.

Ash-free sugar charcoal will completely adsorb a certain maximum amount of Methylene Blue and still leave the solution neutral. During this process of adsorption a considerable quantity of hydrochloric acid is set free but is readily and completely adsorbed by the charcoal. Adsorption of quantities of Methylene Blue greater than the above-mentioned maximum results in the liberation of more hydrochloric acid than can be removed from solution by adsorption.—J. F. S.

Patents.

Mordant-dyeing colouring matters; Manufacture of new ——. Durand & Huguenin, S.A. E.P. 166,530, 11.7.21. Conv., 15.7.20. (*Cf.* U.S.P. 1,403,888; J., 1922, 170 A.)

New mordant dyestuffs, having the probable general formula



(R_1 and R_2 are benzene nuclei which may be substituted by a CH_3 group, and R_2 is a benzene nucleus which may be substituted by NO_2, halogens, or CH_3 groups, and is also in every case preferably substituted by a sulpho group) are prepared by oxidising 1 mol. of a methylene-di-*o*-hydroxycarboxylic acid of the benzene series, substituted in each of its carboxyl groups by an arylamine or substituted arylamine containing nitro, halogen or methyl groups, with 1 mol. of the same or another *o*-hydroxycarboxylic acid. The methylenediarylido-*o*-hydroxycarboxylic acid is formed by condensing an *o*-hydroxycarboxylic acid with an arylamine either before or after condensation with formaldehyde. Oxidation is effected by means of nitrous acid, and anilidosalicylic acid, anilido-*o*-cresotinic acid, and *p*-nitroanilidosalicylic acid are suitable intermediates. The dyestuffs are suitable for dyeing chromed wool in red shades, but give dull and weak tints when used in printing. On sulphonation, however, the dyestuffs are improved in strength and fastness so that they are then suitable for printing together with a chromium mordant. A red dyestuff is prepared by the following method: 106·5 pts. of anilidosalicylic acid dissolved at 20°—25° C. in 700 pts. of sulphuric acid of 66° B. (sp. gr. 1·84) is stirred with 7·5 pts. of paraformaldehyde for several hours. 34·5 pts. of salicylic acid is added and the mixture is afterwards oxidised by the gradual addition, at 30°—50° C., of 30 pts. of sodium nitrite. The mass is then cooled, poured into ice water, and the dyestuff is filtered off, washed, and dried (yield 135—140 pts.). Sulphonation is effected by heating at 90°—95° C. for 1—2 hrs. a solution of the dyestuff in five times its weight of sulphuric acid of 66° B. —A. J. H.

Brown [*sulphur*] *dyestuffs.* Soc. Chim. de la Grande Paroisse. E.P. 169,687, 12.8.21. Conv., 30.9.20.

Brown dyestuffs having a reddish tinge are prepared by treating with alkali polysulphides the 2.4.8- and 2.4.5-trinitro-α-naphthols obtained by successive treatment of the corresponding isomeric dinitronaphthalene compounds with fuming sulphuric acid and dilute nitric acid. For example, 10 kg. of either or both of these trinitronaphthols, 40 kg. of crystalline sodium sulphide, 4 kg. of sulphur, and 8 l. of water are heated at 150° C. until the water has evaporated, whereby the mass thickens and a considerable amount of ammonia is evolved. The temperature is then raised to 170° C. and when evolution of hydrogen sulphide ceases, the product is dissolved in 300 l. of water and the dyestuff precipitated by addition of an acid. The dyestuff obtained from 2.4.8-trinitro-α-naphthol is redder than that produced from the 2.4.5-trinitro-derivative. The sulphur dyestuffs thus produced are fast to light and do not bleed.—A. J. H.

Yellow colouring matters for dyeing animal fibres; Manufacturing ——. F. Günther, Assr. to Badische Anilin und Soda Fabrik. U.S.P. 1,430,899, 3.10.22. Appl., 9.7.20.

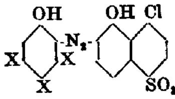
Yellow water-soluble dyestuffs, capable of dyeing wool in even shades of excellent fastness, are made from an aromatic aldehyde and a compound of *o*-nitraniline. The dyestuff molecule has the position para to the NH_2 group unoccupied and is substituted, in the aldehyde residue, by at least one sulphonic acid group.—A. J. H.

Brominated indigoes; Method of making ——. C. J. Strosacker and H. J. Rupright, Assrs. to The Dow Chemical Co. U.S.P. 1,431,606, 10.10.22. Appl., 1.9.20.

Dry indigo is treated, at 50°—90° C. and under approximately atmospheric pressure, in the absence of any diluent or any other reagent, with from 15 to 25% excess of bromine above that theoretically necessary to form the desired substitution product. —J. S. G. T.

[*o-Hydroxy-*]*azo dye.* W. Herzberg and O. Scharfenberg, Assrs. to Akt.-Ges. für Anilin Fabrik. U.S.P. 1,431,655, 10.10.22. Appl., 30.8.21.

o-Hydroxyazo dyestuffs of the general formula



capable of dyeing chrome-mordanted wool in blue shades of very good fastness and which by reduction yield 8-chloro-2-amino-1-hydroxynaphthalene-5-sulphonic acid, and 2-amino-3.4.5-trihalogenated-1-hydroxybenzene are claimed. The alkali salts of these dyestuffs are dark powders soluble in water to form blue solutions, which become violet and red by addition of sodium carbonate and caustic soda respectively and which yield a brownish-orange precipitate by addition of an organic or inorganic acid. —A. J. H.

[*Vat*] *dye.* W. Herzberg and G. Hoppe, Assrs. to Akt.-Ges. für Anilin-Fabrik. U.S.P. 1,431,656, 10.10.22. Appl., 30.8.21.

New dyestuffs, obtained by condensation of naphthosultam-3.4-phenazine with a halogenated quinone derivative, are capable of dyeing fibrous material in yellow to orange shades, fast to chlorine and soap, from an alkaline hydrosulphite vat. The dyestuffs are yellow to orange crystals or powders, slightly soluble in organic solvents but soluble in concentrated sulphuric acid with an orange-red colour.—A. J. H.

Colour lake. U.S.P. 1,431,081. *See* XIII.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Clothes-moth (*Tineola biselliella, Hum.*)*; Researches on* ——. E. Titschack. Z. techn. Biol., 1922, **10**, 1—168. Chem. Zentr., 1922, **93**, III., 945—947.

A zoological study was carried out for F. Bayer u. Co. (*cf.* G.P. 347,723; J., 1922, 541 A) concerning the behaviour of moth toward fifty-two materials, and also the influence of chemical reagents in gaseous, liquid and solid form, temperature, light, moisture, reduced pressure and shaking on the eggs, larvæ and moth. The results obtained with various chemical reagents are tabulated.—A. J. H.

Cellulose. VII. Cellulose copper compounds. K. Hess, E. Mesmer, and E. Jagla. Ber., 1922, **55**, 2432—2443.

It is shown by interpretation of the effects of copper hydroxide and ammonia on the specific rotation of cellulose in the light of the law of mass action that the soluble complex copper compounds of cellulose probably contain the metal and carbohydrate in the ratio, $1Cu:2C_6H_{10}O_5$, but that a different multiple of the $C_6H_{10}O_5$ group is also possible. The isolation of the compound $Na_2[C_{12}H_{18}O_{10}Cu]$, formed by the action of caustic soda on a cuprammonium solution of the biose-anhydride from cellulose (*cf.* Hess, J., 1922, 9 A) or by the action of caustic soda and copper hydroxide on cellulose (*cf.* Normann, J., 1906, 652), considerably strengthens the first conception. (*Cf.* J.C.S., Nov.)—H. W.

Lignin; Reduction of —— and of carbohydrates with hydriodic acid and phosphorus. R. Willstätter, L. Kalb, and G. von Miller. Ber., 1922, 55, 2637—2652.

Lignin obtained from pine or red beech by treatment with hydrochloric acid (sp. gr. 1·21) in accordance with the method of Willstätter and Zechmeister (J., 1913, 822), is converted by hydriodic acid (sp. gr. 1·7) and red phosphorus under pressure at 250° C. into a product which is separated by ether into a non-homogeneous, insoluble portion of high melting point and a soluble portion which is further separated by means of alkali into a feebly acidic product (C 76·50, H 10·39%) and a mixture of hydrocarbons. The latter is separated by successive treatment with acetone and glacial acetic acid into a solid and a liquid hydrocarbon fraction, each of which is free from oxygen. The composition of the mixture approximates to a mean value corresponding with the formula, $CH_{1\cdot4}$; the liquid portion is somewhat richer, the solid somewhat poorer in hydrogen. The liquid hydrocarbons have sp. gr. 0·9 and 1·0 respectively for the fractions of lowest and highest boiling point. The lowest observed molecular weight is 167, the highest 842 (for the solid portion). The two mixtures are an interrelated analogous (not homologous) series, the properties of which are reminiscent of hydroaromatic hydrocarbons. Further treatment of the residue insoluble in ether (see above) with hydriodic acid and phosphorus yields almost exclusively solid hydrocarbons. The latter together with liquid hydrocarbons in the approximate ratio 3:1 are similarly derived from the acidic substance. The hydrocarbons are themselves practically unchanged by further treatment with hydriodic acid and phosphorus. Hexitol, dextrose, xylose, cellulose, and the humus-like substance obtained by the action of hydrochloric acid on dextrose, give mixtures similar to those obtained from lignin when treated with hydriodic acid and phosphorus under like conditions. *n*-Hexyl iodide is not an intermediate product of the change. It appears therefore that the constitution of lignin must be closely related to that of the carbohydrates. (*Cf.* J.C.S., Nov.)
—H. W.

Sulphite liquors; Analytical methods for ——. R. Sieber. Zellstoff u. Papier, 1922, 2, 199—201. (*Cf.* J., 1921, 382 A).

Good results for the free acidity are obtained by Höhn's method when methyl red is used instead of phenolphthalein as indicator. The combined sulphurous acid cannot accurately be calculated from a determination of the total calcium, because the suggested correction for SO_4 of 0·16% is not a reliable constant. The estimation of the sulphate cannot be omitted when carrying out Sander's method (J., 1921, 256 A), and it is necessary to work in an atmosphere of carbon dioxide. This can be generated in the reaction flask from sodium carbonate solution, the corked flask being provided with a small dropping funnel and a delivery tube dipping into a beaker of water. Hydrochloric acid is first introduced through the dropping funnel into the sodium carbonate, and when all the air has been expelled the sulphite liquor is introduced through the funnel. Oxidation of the sulphurous acid might be inhibited by a negative catalyst, such as stannic chloride, and the necessity of a carbon dioxide atmosphere might thus be avoided. The author has devised a method for the rapid filtration of barium sulphite by means of a filter-pump funnel. For this purpose the filter plate is covered with a thick paper filter and a measured quantity of a suspension of kieselguhr of exactly known concentration is first distributed over the filter with very gentle suction. This kieselguhr forms a filter bed which retains the barium sulphate completely even when freshly precipitated, and filters very rapidly. A correction is made for the weight of the dry ignited kieselguhr. In the spent liquors the completely free sulphurous acid is determined by distillation without acidification; this is better than the direct titration with iodine. Total sulphur in spent liquors is determined by a sodium peroxide method: 5 c.c. of the liquor is treated with concentrated sodium hydroxide solution in a nickel crucible and the alkaline liquid evaporated to dryness on an electric hot-plate. A mixture of 3 g. each of sodium carbonate and peroxide is mixed with the powdered residue and the whole is carefully heated over a small flame, combustion being avoided. Afterwards a further 0·5 g. of peroxide is added and the mass brought to fusion. Sulphate is then determined in the melt after dissolving in water and treating with bromine.
—J. F. B.

Sulphite wood pulp; Reddening of —— and its cure. E. Heuser and S. Samuelsen. Papierfabr., 1922, 20, 1249—1254, 1285—1288, 1321—1326.

The red coloration is liable to develop not only in underboiled sulphite pulps but also in easy-bleaching varieties. The presence of a certain amount of moisture is necessary for the development of the red colour, which then appears under the influence of light and air or other mild oxidising agents. It is destroyed by excess of oxidising agents and permanently disappears in the operation of bleaching. The action of reducing agents such as hydrosulphite, discharges the red colour, but this reappears on subsequent oxidation; similarly, the discharge which is effected by dilute mineral acids and by alkalis is only temporary and the red colour returns after the pulp is washed. It would seem that the substance which produces the red coloration is fixed on the original cellulose in the reduced form; none of the attempts to separate it by extraction were successful. Very similar reactions are shown by vanillin and protocatechuic aldehyde; these substances are allied to lignin, and the conclusion arrived at is that the chromogenic substance is derived from the lignin or lignosulphonic acid, possibly modified by the digestion process and fixed on the cellulose either by aldol condensation or after the manner of a dyestuff. The problem of destroying the tendency to reddening without having recourse to a definite bleaching of the pulp has been solved, by the observation that, whereas with the majority of oxidising agents a substantial quantity is required for the permanent destruction of the colouring matter, in the case of potassium persulphate in acid solution, 0·5% is sufficient. The pulp is treated with 0·5% of its air-dry weight of the persulphate and 0·5% of aluminium sulphate and left in the stuff-chest for 9 hrs. It is then ready for use by simple draining without washing. The treated pulp is in no sense bleached, but the lignin residues are so far changed that the tendency to subsequent reddening is completely eliminated.—J. F. B.

Cellulose derivative [butyrate] and process of preparing same. A. D. Little, Inc., Assees. of G. J. Esselen and H. S. Mork. E.P. 182,820, 9.3.21. Conv., 10.4.20.

When butyric acid containing small quantities of water is used as the catalyst carrier (*cf.* U.S.P. 1,425,580; J., 1922, 748 A), the mixture separates into two layers, the lower of which contains practically the whole of the catalyst. This separation is prevented by the addition of small quantities of such substances as methyl, ethyl, or butyl alcohol, acetone or the like. A suitable impregnating bath has the following composition: sulphuric acid (sp. gr. 1·84) 0·5—0·6%, alcohol 5—7·5%, butyric acid 94·5—91·9%. The cellulose is soaked for 90 mins. in this solution, pressed until it contains 1¼ times its weight of solution, and esterified as described in E.P. 167,143 (J., 1922, 748 A).—D. J. N.

Cellulose ether solvent and composition. Composition containing cellulose nitrate and cellulose ether and solvent used therein. S. J. Carroll, Assr. to Eastman Kodak Co. U.S.P. (A) 1,431,905 and (B) 1,431,906, 10.10.22. Appl., 1.4.21 and 25.4.21.

(A) A viscous composition consists of an alkyl ether of cellulose dissolved in a solvent containing 90—10 pts. of xylene and 10—90 pts. of a lower monohydroxy aliphatic alcohol (*cf.* U.S.P. 1,429,188; J., 1922, 807 A). (B) The composition consists of nitrocellulose and cellulose ether dissolved in a mixture containing methyl alcohol, ethyl acetate, and chloroform.—A. J. H.

Asbestos paper, sheets and the like, and articles made therewith. N. Sulzberger. E.P. 186,409, 24.6.21.

Pure asbestos paper (containing no organic binders) is made by drying a pulp containing 50 pts. of long-fibre asbestos and 6 pts. of a colloidal solution of aluminium silicate prepared with the aid of tannic acid and ammonia. Alternatively, asbestos sheets containing an organic binder and preferably an oxidising agent such as sodium nitrate or nitrocellulose, are heated at a temperature sufficient to destroy the organic binder. Asbestos material prepared by this process is suitable for cigarette wrappers, insulating materials, and carriers for catalysts.—A. J. H.

Parchment paper or vulcanised fibre and process for making some [from nitrocellulose]. B. Herstein. U.S.P. 1,429,427, 19.9.22. Appl., 6.4.20.

Sheets of nitrocellulose paper containing not more than 4·5% of nitrogen are superimposed, and cemented together by the gelatinising action of an alkali.—D. J. N.

Flax fibre; Process for recovering [making high-grade paper pulp from] ——. R. E. Rindfusz and V. Voorhees, Assrs. to American Writing Paper Co. U.S.P. 1,430,115, 26.9.22. Appl., 15.11.19.

Flax tow is digested with alkaline solutions under pressure, washed, treated at the ordinary temperature with a solution containing an oxy-acid of nitrogen, and again subjected to an alkaline treatment to complete the removal of ligneous shive material.—D. J. N.

Metallised paper [for making electric cables]. M. Höchstädter. E.P. 186,363, 29.3.21.

Metallised paper, more especially for use in the manufacture of electric cables in accordance with E.P. 7766 of 1914, is prepared by spraying a continuous conducting layer of molten metal upon paper. The nozzles of the spraying apparatus are capable of oscillation transversely to the direction of motion of the paper during the spraying process. Preferably spelter is used as the sprayed metal, and after leaving the spraying apparatus the paper is passed between rollers to be smoothed and perforated. The resulting material is highly porous and cables constructed therefrom can be impregnated with liquids in the usual manner.—J. S. G. T.

Paper; Method of removing ink from print ——. H. R. Eyrich and J. A. Schreiber. E.P. 186,372, 17.5.21.

See U.S.P. 1,421,195 of 1922; J., 1922, 628 A. Bentonite is a very fine-grained clay and its action is apparently that of a protective colloid, which forms a fine suspension in the alkaline liquid and renders the particles of pigment capable of removal through the matted fibres on the surface of the drum washer.

Graphitised vulcanised fibre and methods in preparing the same. E. G. Acheson, jun. E.P. 172,924, 7.7.21. Conv., 14.12.20.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Cotton mercerised by means of sodium hydroxide or sodium chromite (alkaline chrome mordant); Some important but overlooked properties of ——. J. Pokorny. J. Soc. Dyers and Col., 1922, 38, 248—250.

Mercerisation imparts to cotton slightly basic properties whereby it attracts acid dyestuffs (including direct cotton dyes) containing sulphonic or carboxylic groups, from cold or hot acidified solutions. Hanks of mercerised cotton dyed in acid and alkaline solutions of Benzopurpurine 4B acquired the same brightness and depth of shade. This property of mercerised cotton is diminished by treatment with hot dilute acids, so that it is probably due to the formation of an active but labile basic compound. The formation of this basic compound increases with the strength of caustic soda used in mercerisation. Cotton also obtains stronger basic properties when simultaneously mordanted and mercerised by means of Koechlin's alkaline chrome mordant, and is then capable of fixing from cold or hot dilute, neutral or slightly acid dye-baths, all kinds of acid colours in much deeper shades than those obtained by the usual direct dyeing methods. The more sulphonated the dyestuff, the easier is the dyeing, *e.g.*, dark indigo shades are obtained by dyeing alkaline chrome-mordanted cotton in cold or hot dilute solutions of Diamine Sky Blue. Under these conditions, Eriochrome Azurol B and Alizarin Saphirol B yield dyeings very fast to hot soaping, but the fastness of other dyestuffs varies considerably. In most instances, the dye-liquor, even in the cold, is easily exhausted. The shade of alkaline chrome-mordanted cotton dyed in the cold with dyestuffs containing hydroxyl groups in special positions (*e.g.*, Eriochrome Azurol B) is altered in tone and becomes much faster to soap when steamed without pressure. The mordanted cotton may be further mordanted by steeping it in solutions containing suitable metallic salts. Technically valuable shades have been obtained by impregnating alkaline chrome-mordanted cotton with diazo or tetrazo solutions and subsequently treating it with solutions (not alkaline) containing suitable naphtholic compounds. Alternatively the mordanted cotton may first be impregnated with intermediates such as H-acid, J-acid, and chromotropic acid and then treated with suitable diazo or tetrazo solutions. For example, an orange shade, fast to soap (faster after steaming), is produced on alkaline chrome-mordanted cotton when it is steeped in 50 c.c. of a solution (not alkaline) containing 1·38 g. of salicylic acid and 0·85 c.c. of caustic soda of 76° Tw. (sp. gr. 1·38), afterwards rinsed and then immersed in a solution of diazotised *p*-nitraniline and subsequently soaped. Under the same conditions, the colour is not retained by unmordanted cotton.—A. J. H.

Dyeing of woollen piece goods; New process for obtaining special effects in the ——. F. Münz and R. Haynn. Chem.-Zeit., 1922, **46**, 945—946.

When wool is treated with acetic anhydride in the presence of a catalyst, such as hydrochloric acid, phosphoric acid, organic sulphonic acids, and particularly sulphuric acid, it retains its physical properties (except that it can be more easily "milled") but permanently resists acid dyestuffs, so that the production of white effects in dyed piece goods is possible. The treated wool contains no sulphuric acid and when heated with 50% sulphuric acid yields no acetic acid by hydrolysis. The injurious action of the sulphuric acid on the wool may be diminished without reducing its catalytic action by neutralising a part of it with a weak organic base such as pyridine or dimethylaniline. The wool may also be padded with sulphate of aluminium or chromium, or other easily dissociated salts of sulphuric acid. Previously dyed wool may also be treated (only shades obtained by means of acid alizarin dyestuffs are considerably changed), but the consequent decrease in fastness to washing, milling, etc., must be corrected by an after-chroming treatment. The process is carried out in rotating water-jacketed closed aluminium drums. For 1 kg. of wool, 1 l. of acetic anhydride, 4 l. of acetic acid, 140 g. of sulphuric acid (monohydrate), and 77 g. of dimethylaniline are used, but for 1 kg. of dyed wool, the sulphuric acid and dimethylaniline are replaced by 60 g. of sulphuric acid (monohydrate). The wool is treated for 1½ hrs. at 57°—58° C., and is then washed and dried, but dyed wool, after washing, is treated with a solution containing 20% of chromium acetate of 20° B. (sp. gr. 1·16) and 4% of formic acid (85%) for ¾ hr. at 75° C. and is then washed and dried. Acetic acid used in the treatment is recovered as a 30% solution and is suitable for use in the mordanting and dyeing of wool.—A. J. H.

Dyed fabrics; Influence of gases on the fastness of ——. E. Ristenpart and P. Wieland. Textilber., 1922, **3**, 397. (*Cf.* Ristenpart, J., 1921, 505 A.)

Although Schiff's reagent is admitted to be suitable for use in the determination of formaldehyde in the distillate obtained by steam distillation of fibrous materials containing formaldehyde, the statement of Heermann (J., 1922, 290 A) that this reagent is at least as sensitive as Cohn's reagent (a mixture of sulphuric acid and resorcinol) is disputed. Moreover, in the testing of materials for formaldehyde, unreliable results may be obtained if the material is directly immersed in Schiff's reagent. The difficulty of producing dyed fabrics fast to formaldehyde is increased by the discovery that compound shades are not necessarily fast even when produced by means of dyestuffs which are individually fast to formaldehyde. In explanation of this fact, it is suggested that the formaldehyde molecule suffers internal rearrangement to form

$$\begin{matrix}\mathrm{H}\\\mathrm{H}\end{matrix}\!>\mathrm{C}<^{\mathrm{O}-}$$

and is thereby able to unite with two molecules of dyestuff. It is recommended that all packing materials for dyed goods should be free from formaldehyde.—A. J. H.

Fastness of dyestuffs. Setlik. *See* IV.

Patents.

Dyeing silk black. O. Y. Imray. From Gebr. Schmid. E.P. 174,947, 3.2.22.

In a rapid process for weighting silk which is to be dyed black, the silk is weighted by the usual tin-phosphate process and is then treated in a boiling foam bath containing hæmatein and silkworm chrysalides. For example, 100 kg. of tin-weighted silk is immersed for 15—30 mins. in a boiling foam bath containing 2000 l. of water, 70 kg. of hæmatein, and 20 kg. of silkworm chrysalides previously boiled in 50 l. of water. Alkaline substances such as soap, sodium carbonate, alkali silicate, soda-lye, or potash-lye may be added, and the exhausted bath may also be used, after addition of an aniline dyestuff, for dyeing the treated silk.—A. J. H.

Fixing of [*ice-*] *colours upon textile fibres.* G. Aris. E.P. 186,086, 24.3.21.

In the fixing of ice colours (*e.g.*, Para Red) on fabrics prepared with a phenolic salt (*e.g.*, sodium β-naphtholate), the addition to the diazo solution of 0·5—5% of a diazotisable azo derivative of the amine used as the diazo component, increases the affinity of the fibres for the ice colour subsequently formed. Hence, printing pastes to which this addition is made, can be diluted 16% and a corresponding reduction can also be made in the strength of the β-naphthol solution. For a developing solution containing diazotised aniline, aminoazobenzene is a suitable azo derivative to add.—A. J. H.

Dyeing; Fast ——. V. Villiger and H. Von Krannichfeldt, Assrs. to Badische Anilin- und Soda-Fabrik. U.S.P. 1,431,136, 3.10.22. Appl., 9.9.20.

See E.P. 168,447 of 1920; J., 1921, 730 A.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Nitric acid; Air-bleaching of ——. W. G. Whitman and L. Evans. Chem. and Met. Eng., 1922, **27**, 686—688.

The rate of removal of lower oxides of nitrogen existing in a concentration, N, in nitric acid solution, is given by the equation $-dN/d\theta = \beta N$, where β is a constant for a given temperature and rate of flow of air. The results of laboratory experiments are given confirming this equation and establishing that β varies directly with the rate of flow of air and with the temperature, being doubled with each rise of 5° C. The advantage of bleaching at a high temperature is thus very great, and there is also a saving of nitric acid, the vapour pressure of which rises much more slowly than does the partial pressure of the lower oxides existing in a 1% solution. Values for β, the "bleaching coefficient," for given conditions obtained in laboratory experiments were found to be within 10% of the results of plant practice.—C. I.

Ammonia; Oxidation of ——. The work of the Sheffield [U.S.A.] experiment station. H. A. Curtis. Chem. and Met. Eng., 1922, 27, 699—703.

An account is given of data obtained in 1918 on an experimental plant with a capacity of 500 lb. of nitric acid per day. The conclusions reached include the following:—An alloy of platinum with 1% of iridium is as efficient a catalyst as pure platinum. The optimum temperature for the reaction is higher than usually believed and, in the absence of heat exchangers, electrical heating of the gauze is indispensable. The highest oxidation efficiencies (above 90%) were obtained with a gauze temperature of about 800°—880° C. The improved efficiency obtained by using two gauzes electrically insulated from each other, of which the first only is heated, is partly but not entirely due to heat conservation. Ammonium nitrate solution cannot be substituted for water in the absorption towers, as it is decomposed. An activated charcoal catalyst placed in the absorption system after the first or second tower and maintained at a temperature above the dew point of the gas passing, increased the rate of oxidation of the nitric oxide fourteen times. This catalyst cannot be placed earlier in the system, as in concentrated nitric oxide (10%) it burns. A survey of future lines of advance in this process is given.—C. I.

Nitric oxide; Comparison of methods for the estimation of ——. A. Klemenc and C. Bunzl. Z. anorg. Chem., 1922, 122, 315—331.

Nitric oxide was prepared according to the method of Emich (Monatsh., 1892, 13, 73); the product contained about 1%of impurity and was purified by fractionation, using liquid air. The estimation of the gas by passing it over heated copper was found to give reliable results. Unreliable values were obtained by combustion with hydrogen in the Drehschmidt platinum capillary (Von Knorre and Arndt, J., 1899, 1156), by the method of Baudisch and Klinger (J., 1912, 1178), and by absorption with ferrous sulphate. Good results were obtained by absorption of the gas with acid bromate or *N*/5 permanganate and estimation of the excess of absorbent. The last-named method can also be used in the presence of carbon dioxide and other gases. —W. T.

Liquid sulphur dioxide; New system of making —— in South America. H. J. Paoli. Giorn. Chim. Ind. Appl., 1922, 4, 349—352.

Large quantities of liquid sulphur dioxide are used in South America, especially in Argentina, for making ice, for refrigerating machinery in the frozen meat industry, in the manufacture of wine, and for the disinfection and preservation of fruit. The method of manufacture used in the Sarandi (Buenos Ayres) works of Sociedad de Productos Quimicos "La Sulfurica," started in 1914, is described. Sulphuric acid being ruled out by its high price and pyrites by its inaccessibility, sulphur is used as raw material. The products of combustion of the sulphur are passed from the burners through a leaden pipe to the base of a packed tower, down which falls a fine water spray. The acid solution obtained passes into a coil enclosed in a heater through which steam circulates under pressure, and overflows into a gasifying tank heated by the furnace used for the sulphur burners, part of the sulphur dioxide being thus liberated. The liquid is then heated in a fire-heated boiler, into which the heater also may be discharged; here the last traces of sulphur dioxide are expelled. If the pressure in the heater is increased, the quantity of heat also increases, so that the spray descending the tower may be increased until the whole of the sulphur dioxide is absorbed and the liquid delivered into the gasifier almost at the boiling point. The rest of the plant consists of cooling coils for the gas, a coke tower, a sulphuric acid filter for drying the gas, and a compressor. With normal working 150 pts. of sulphur yields 270 pts. of the liquid anhydride. Details of the plant are given.—T. H. P.

Sulphur dioxide; Solubility of —— in suspensions of calcium and magnesium hydroxides. W. T. Smith and R. B. Parkhurst. J. Amer. Chem. Soc., 1922, 44, 1918—1927.

The solubility of sulphur dioxide in water, milk of lime, and milk of magnesia has been determined at partial pressures of sulphur dioxide up to 760 mm. and temperatures from 5° C. to 60° C. Varying proportions of calcium and magnesium hydroxide were used in suspensions of a total alkalinity of 1 g.-equiv. per l. The concentration of sulphur dioxide as sulphurous acid is proportional to its partial pressure. With solutions of the same alkali concentration the percentage salting-out effect (*i.e.*, 100 times the ratio of the difference between the solubility of sulphur dioxide in water and as free sulphurous acid in the solution under examination to the solubility of sulphur dioxide in water under the same conditions of temperature and pressure) increases with, but more than in proportion to, the temperature. With solutions of constant temperature the percentage salting-out effect increases with the alkali concentration but is less than proportional to it. Varying proportions of calcium and magnesium hydroxide have no effect on the equilibrium concentration of sulphur dioxide as sulphurous acid. —J. F. S.

Sulphur tetroxide; Existence of ——. F. Meyer, G. Bailleul, and G. Henkel. Ber., 1922, 55, 2923—2929.

When sufficient energy is imparted, the action of the silent electric discharge on a mixture of sulphur dioxide and oxygen leads to the formation of more highly oxidised substances than sulphur heptoxide. It is essential that a relatively large excess of oxygen or ozone should be present and that the temperature should be kept low. The most fully oxidised product yet obtained corresponds with the formula, $SO_3,2SO_4$, but it is improbable that the limits of oxidation have yet been reached. Berthelot's sulphur heptoxide (Comptes rend., 1878, 86, 20, 288) is probably a mixture of sulphur trioxide and sulphur tetroxide in equimolecular proportions. (*Cf.* J.C.S., Dec.)—H. W.

Ammonium carbonate-carbamate equilibrium. C. Faurholt. Z. anorg. Chem., 1922, 122, 132—134.

A reply to Wegscheider's theoretical paper (Z. anorg. Chem., 1921, 121, 110). The author shows that his results for the above equilibrium (*cf.* J., 1922, 292 A) are in fair agreement with those obtained by Burrows and Lewis and Fenton. The disagreement between Wegscheider's conclusions and those of the present author is largely due to different values for the ionisation-constant of carbamic acid. According to Wegscheider this acid is so weak that its ammonium salt is completely hydrolysed in aqueous solution, whereas the author found by colorimetric estimation of hydrogen ions that the ammonium salt is not hydrolysed to any appreciable extent.—W. T.

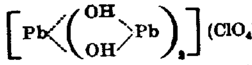
Calcite and aragonite; Solubilities of ——. H. L. J. Bäckström. Med. K. Vetenskapsakad. Nobelinst., 1922, 4, [11], 1—11.

The solubilities of calcite in the form of Iceland spar and of synthetic aragonite in water in presence of carbon dioxide were determined at 9°, 25° and 35° C. As the point of equilibrium is approached, either from the supersaturated or from the undersaturated side, the reaction becomes very slow, especially in the case of calcite, but the following figures in g. p. l. are probably accurate to 0·1%: calcite, 1·30 at 9°, 0·943 at 25°, and 0·765 at 35° C.; aragonite, 1·46 at 9°, 1·066 at 25°, and 0·876 at 35° C. The most probable value of the transition temperature, calculated from these figures, is -43° C. (*Cf.* J.C.S., 1921, ii., 317).—E. H. R.

Basic lead salts; Constitution of ——. R. Weinland and R. Stroh. Ber., 1922, 55, 2706—2718.

The presence of polynuclear cations in several forms has been established by preparative substitution in the case of lead salts. Thus, in the basic perchlorates

$$\left[\mathrm{Pb}{<}\begin{matrix}\mathrm{OH}\\ \mathrm{OH}\end{matrix}{>}\mathrm{Pb}\right](\mathrm{ClO_4})_2,\ 1\cdot5\mathrm{H_2O}\quad \text{and}$$



$$\left[\mathrm{Pb}{<}\left(\begin{matrix}\mathrm{OH}\\ \mathrm{OH}\end{matrix}{>}\mathrm{Pb}\right)_2\right](\mathrm{ClO_4})_2,$$

the perchlorate residues could be replaced by other acid radicles by double decomposition. The stability of the metal-ol cations in aqueous solution is not comparable with that of the typical metallic ammines, since the above basic perchlorates are to some extent decomposed into new basic salts when their solutions are diluted. The presence of such lead-ol complexes in basic lead acetates has also been established by the substitution method in the case of the basic lead acetate of the German Pharmacopœia V.; one such ion is identical with that contained in the first perchlorate mentioned above. Lead acetate may be regarded as the acetate of a polynuclear lead acetato cation. In aqueous solution more than one such cation is undoubtedly present since the action of perchloric acid on lead acetate in neutral or acetic acid solution yields the perchlorates of four different acetato cations.
—H. W.

Rare earths; Separation of —— by basic precipitation. III. Quantitative separation of cerium from the other earths. W. Prandtl and J. Löschl. Z. anorg. Chem., 1922, 122, 159—166.

The separation is based on the fact that the ceric hydroxide is a weak base and its salts are largely hydrolysed. Cerous nitrate mixed with the nitrates of the other rare earths was oxidised by triammino-trinitrato-cobalt in acid solution and a quantitative precipitation of ceric hydroxide was obtained, $Ce(NO_3)_3 + [Co(NO_2)_3(NH_3)_3] + 4H_2O = Ce(OH)_4 + Co(NO_3)_2 + 3NH_4NO_3 + HNO_3$. The formation of free acid prevents the precipitation of the other rare earths.—W. T.

Rare earths; Separation of —— by basic precipitation. IV. W. Prandtl and J. Rauchenberger. Z. anorg. Chem., 1922, 122, 311—314.

The influence of cadmium nitrate on the equilibria between the nitrates of the rare earths and ammonia in ammonium nitrate solutions of various concentrations has been investigated. The conditions were the same as in previous investigations (J., 1922, 292 a). The presence of cadmium nitrate increased considerably the amount of rare earths, especially lanthanum, kept in solution, this increase being much more marked than in presence of zinc nitrate.—W. T.

Hydrogen gas; Spontaneous incandescence of substances in atomic ——. R. W. Wood. Proc. Roy. Soc., 1922, A 102, 1—9.

Metals, certain oxides, and other substances when introduced into a stream of atomic hydrogen are raised to incandescence, owing to the surface of the substance acting as a catalyst in bringing about the re-combination of the atoms. Fire-polished glass surfaces have a comparatively feeble catalysing power, but fractured surfaces cause the re-combination of the atoms, and are strongly heated.—J. F. S.

Patents.

Green chrome oxide; Process of making ——. A. L. D. d'Adrian. U.S.P. 1,429,912, 19.9.22. Appl., 5.11.21.

Alkali chromate (100 pts.) is heated with ammonium sulphate (50 pts.) to 400° C. for from 15 mins. to 2 hrs. The product is lixiviated with water to remove the soluble constituents.—T. A. S.

Lithium and potassium [salts]; Process for extracting —— from lithium-potassium ores and also forming potassium alum from such ores. G. E. Bailey and A. E. Sedgwick. U.S.P. 1,430,877, 3.10.22. Appl., 14.2.21.

Lithium-potassium ore is mixed with potassium sulphate and heated to a temperature not exceeding 1500° F. (about 815° C.).—L. A. C.

Hydrogen peroxide; Method of producing solutions containing ——. Deutsche Gold- und Silber-Scheideanstalt vorm. Roessler, and O. Liebknecht. E.P. 186,871, 16.2.22.

See G.P. 355,866 of 1916; J., 1922, 754 a.

Separating hydrocarbon from aluminium chloride. U.S.P. 1,430,109. *See* IIa.

VIII.—GLASS ; CERAMICS.

Silica; Influence of heat on the microscopic properties of —— in its different mineral forms. J. T. Robson. J. Amer. Ceram. Soc., 1922, 5, 670—674.

The refractive indices of sand, quartz rock, chalcedony and flint alone and when used in a porcelain body of the composition felspar 20%, kaolin 45%, silica 35%, were determined before and after firing to cone 13 and 14. Flint and chalcedony were transformed into cristobalite before sand and quartz rock, which appeared to alter at about the same temperature.—H. S. H.

Porcelains; Talc as a flux for high-tension insulator ——. R. Twells, jun. J. Amer. Ceram. Soc., 1922, 5, 675—684.

A typical high-tension insulator body of the general formula 0·21 K_2O, 1·0 Al_2O_3, 4·45 SiO_2 was used as a standard, the K_2O being partially replaced by MgO and the RO content being varied between 0·14 and 0·30 equivalent, talc being used as the source of magnesia. The bodies were fired to temperatures below cones 9 and 13 and were tested for absorption and transverse strength. The results at cone 10½ showed that a small addition of talc greatly decreased the percentage of felspar necessary for vitrification, but additional small amounts of talc had much less effect than the first small addition. About 0·16 equivalent of RO was needed for vitrification at this temperature when small percentages of talc were used. The transverse strength in properly vitrified bodies was increased by the addition of MgO at the expense of K_2O. Vitrified bodies of this general type showed little improvement, if any, over regular triaxial porcelain. It is suggested that the effect of replacing the felspar entirely, or almost entirely, by talc, and the use of higher temperatures to obtain vitrification should be tried.—H. S. H.

Terra cotta; Data on viscosity of Indiana clay slip with electrolytes in regard to the casting of ——. H. E. Davis. J. Amer. Ceram. Soc., 1922, 5, 702—712.

Slips were prepared with Indiana clay, using as electrolytes sodium carbonate, sodium silicate, a mixture of sodium carbonate and silicate in equal proportions, gallic acid and tannic acid. The relative viscosities were determined with a flow viscometer and by measuring the thickness of wall cast in a given time. Sodium carbonate proved the most suitable electrolyte. It produced maximum fluidity in the slip, which did not settle out heavily, and on casting produced a uniformly thicker wall than that obtained by using other electrolytes. Tannic acid was very satisfactory, but so much was required that its use was not commercially practicable. —H. S. H.

Enamels; Wet process —— *for cast iron.* R. R. Danielson and H. P. Reinecker. J. Amer. Ceram. Soc., 1922, 5, 647—669.

The effect of varying composition and treatment on wet process enamels for cast iron has been studied, compositions used in dry process enamelling having served as the basis for the work. Sintering of most ground coat frits was found desirable in order to obtain the best adherence to the castings. Clay gave the best results as a mill addition for the ground coats, flint and felspar being less satisfactory. Excessive additions of clay or flint produced flaking, while felspar tended to develop blistering. About 15% of clay or 10% each of clay and flint are recommended for mill additions for the ground coats. Excessive additions of any one flux were not desirable and the best results were obtained when sodium, lead, and boric oxides were combined in more or less definite proportions. Sodium oxide in excess of about 10% gave rise to blistering. Boric oxide increased the firing range of the ground coats and was preferable to lead oxide on that account, although it tended to promote crawling of ground coats high in boric oxide if they were applied somewhat heavily. The composition of the best ground coats developed are given. Cover enamels were smelted in the usual way. The mill additions consisted of 5% of clay, 8% of tin oxide, 45% of water, all based on the weight of the dry frit. For the best results the cover enamel must be adapted to the ground coat in refractoriness. Boric acid increased the firing range of the enamels but tended to promote crawling, although this was less pronounced in the case of the more fusible compositions. Boric oxide improved the opacity when substituted for such fluxes as sodium and lead oxides. Cryolite increased the opacity but additions above 10%, based on the melted weight, tended to promote crawling. The compositions of the best cover enamels developed are given. —H. S. H.

Patents.

Annealing [glass, porcelain, metals], and apparatus used therein. A. Hilger, Ltd., and F. Twyman. E.P. 186,160, 21.6. and 14.11.21.

A process of annealing depending on the deformation of a rod of the substance to be annealed when maintained under stress has been described (E.P. 114,183; J., 1918, 242 A). The time of relaxation of a substance is determined by subjecting a piece of the same substance as that to be annealed to heat, maintaining the piece under sufficient stress to deform it a determined amount, and either periodically removing the stress or applying a further stress tending to increase the deformation so that the piece ceases to support the stress at any desired degree of annealing before the annealing process is completed. An apparatus is described for ascertaining the time of relaxation of a substance maintained under stress a definite amount, means being provided for adding additional stress. (*Cf.* J., 1921, 468 A.)—H. S. H.

Glass-tank furnace. J. E. Hurley. U.S.P. 1,390,614, 13.9.21. Appl., 15.6.20.

The walls of a glass-tank furnace are composed of tanks containing water. The inner walls of the tank are lined with fibrous material (wood) spaced from the walls by means of corrugated wire mesh or the like, and the space so formed between the lining and the wall communicates by suitable openings with the interior of the tank. With this arrangement there is a continuous circulation of water from the interior of the tank through the space between the walls and the wooden lining, and the latter is protected against the action of the heat of the furnace.—A. C.

Glass; Process of, and mixture for making ——. A. L. D. d'Adrian. U.S.P. 1,430,725, 3.10.22. Appl., 21.7.21.

A bromine salt is added to the mixture usually employed for making glass.—J. S. G. T.

Plastic moulding material [clay]; Process of preparing ——. O. Gerlach and C. B. Lihme, Assrs. to The Industrial Research Laboratories. U.S.P. 1,390,435, 13.9.21. Appl., 15.12.17.

The necessity for ageing clay mixtures, in order to attain the requisite plasticity, prior to moulding, is obviated by addition of sulphite-cellulose waste liquor to the mixture. The tendency of the plastic mixture to tear or break when being forced into the mould, owing to adhesion to parts of the moulding apparatus, is overcome by addition of a small quantity of ground petroleum coke to the clay mixture.

Metallic [zirconium] oxide; Article of fused —— *and process of producing the same.* A. L. D. d'Adrian, Assr. to A. L. Duval d'Adrian Chemical Co. U.S.P. 1,430,724, 3.10.22. Appl., 25.2.21.

Fused zirconium oxide is ground, mixed with a suitable binder, and moulded to shape. The moulded article is heated to a dull red heat between spaced carbon electrodes, and finally to a temperature of about 2500° C. by passing current through it, whereby the particles of oxide become fused together.—J. S. G. T.

Kiln for burning refractory bricks (silica etc.), particularly those with a lime bond. H. Koppers. G.P. 356,037, 6.7.21. Addn. to 347,672.

In a kiln of the type described in the principal patent (J., 1922, 548 A), the firing chamber is operated on the intermittent principle and the preheating and cooling chambers continuously. The preheating and cooling chambers slope down towards the cool ends so that by means of the natural upward draught the air and the waste gases form layers of uniformly decreasing temperature. The heating and cooling processes are thus completely under control and a high degree of efficiency is obtained.—G. F. M.

Sheet glass; Apparatus for drawing ——. W. J. Mellersh-Jackson. From Libbey-Owens Sheet Glass Co. E.P. 186,479, 28.7.21.

Tank furnaces principally for use in glass manufacture; Bridge walls for ——. R. Haddan. From Corning Glass Works. E.P. 186,547, 24.12.21.

IX.—BUILDING MATERIALS.

Patents.

Impregnation of wood. Soc. de Recherches et de Perfectionnements Industriels. E.P. (A) 168,048, 26.7.21, and (B) 179,129, 27.7.21. Conv., 20.8.20 and 19.4.21.

(A) By mixing an ionised non-colloidal solution with the emulsion to be injected into wood for its preservation, a state of deferred precipitation of the antiseptic from the emulsion is obtained. (B) The degree to which precipitation of the antiseptic is retarded is regulated by varying the quantity and concentration of the ionised solution.—J. B. P.

Bricks; Process for making —— and their products. G. B. y Hernandez. U.S.P. 1,430,991, 3.10.22. Appl., 27.9.20.

Cement, fine gravel or sand, and coal scoria are added to a pasty mixture of quicklime and an astringent solution, and the mixture finely pulverised, moulded to shape, and dried.
—J. S. G. T.

Asphalt or like hydrocarbonaceous material; Fire-resisting ——. J. H. Young, and H. H. Robertson Co. E.P. 186,861, 6.12.21.

Insulating and building material, and method of producing same. T. A. Eklund and C. G. Löfveberg. U.S.P. 1,392,127, 27.9.21. Appl., 11.3.20.

See E.P. 140,431 and 142,111 of 1920; J., 1921, 149 A.

Paint for use with magnesium oxychloride cements. E.P. 186,231. *See* XIII.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Iron-bearing materials; Sintering ——. R. L. Lloyd. Min. and Met., Oct., 1922, 17—19.

Iron blast-furnace flue dust, owing to its carbon content, on sintering in a Dwight-Lloyd furnace usually gives sinter of a very good quality; but if the carbon (coke) content is too high the sinter becomes very friable. The furnace works at its maximum capacity and the product is strongest and most massive when the fines contain 8% of coke; dust containing larger percentages should be mixed with pyrites cinders or fine ores to reduce the carbon to 8% For fine iron-ore concentrates from 8 to 3% of coke fines is sufficient according to whether the ore is magnetic or non-magnetic. The product in all cases is a coke-like mass of ferrosoferric oxide, Fe_3O_4, which is exceedingly porous and eminently suitable for blast-furnace work, being very quickly and smoothly reduced by the gases; in addition practically all the sulphur in the ore is removed in the process.—A. R. P.

Cast-iron; Modification of —— by heat treatment. J. Durand. Comptes rend., 1922, 175, 522—524.

An attempt to determine the conditions which cause the increase in volume of castings and to estimate the degree of importance of the various factors affecting it. The experiments were carried out by means of a dilatometer and the samples used measured 50 mm. in length and 8 mm. in diameter. A diagram is given which shows the growth of a specimen of known composition which was submitted to 5 cycles of temperature change (between 600° and 900° C.), and the author points out its agreement with the results obtained by Charpy (Soc. Chim. de France, May 16, 1908). The increase becomes smaller on each successive heating, as the amount of free graphite deposited, which is the cause of the increase in volume, has increased at each stage. As the growth varies inversely with the rate of heating and directly as the silicon content, it is only of importance when the silicon is high and the casting is heated slowly. It follows that stresses will be set up in the material if the temperature varies from one point to another during heating.—H. J. E.

Graphitisation in a carbon tool steel. H. S. Rawdon and S. Epstein. Chem. and Met. Eng., 1922, 27, 650—651.

A peculiar type of black fracture in an annealed tool steel (*cf.* Green, J., 1922, 713 A) was examined. Three distinct zones, a light-coloured casing, a black interior, and a light-coloured pencil of material at the axis were evident even in the sawn face of the bar. Under progressive hardening treatments, the light-coloured layer showed a martensitic structure, and globular cementite, which later dissolved in the matrix. In the dark-coloured area, each black spot acted as the centre for the formation of martensite in the ferrite matrix, and after severe treatment the black nuclei (graphite?) persisted. A troostitic structure was shown in the centre portion after mild hardening, changing to martensite under more severe conditions. In the initial state of the material all the carbon in the black zone was in the graphitic form, and no other feature of composition pointed to the unusual behaviour of the specimen.—C. A. K.

Alloys of electrolytic iron with carbon and manganese; Preparation and mechanical properties of vacuum-fused ——. R. P. Neville and J. R. Cain. Trans. Amer. Electrochem. Soc., 1922, 203—218. [Advance copy.]

Alloys containing 0—1·6% C and 0—1·6% Mn were prepared from electrolytic iron by melting in a magnesia crucible *in vacuo*. The ultimate strength was increased by carbon up to 1% but not uniformly with the carbon content. The presence of manganese in the carbon steels increased the strength. The addition of carbon rapidly and progressively decreased the reduction in area and elongation to a value little above zero when the carbon content was 1%, but the value of the proportional limit was influenced to a less degree. Manganese had only a slight effect on the properties of iron in the absence of carbon, but the effects of manganese and carbon were each influenced by the presence of the other. The first addition of manganese served to deoxidise the metal, forming oxides which separated the grains and tended to decrease the strength.—C. A. K.

Blister copper bars and pigs; Water in ——. A. R. Ledoux. Min. and Met., Oct., 1922, 7—9.

The upper surface of pigs of blister copper is generally very porous, and attention is drawn to the possibility of shipments that have been exposed to rain containing considerable quantities of water which does not dry out after exposure to sun. In some shipments examined, the water content amounted to between 4 and 16 lb. per ton. The moisture content of a shipment is determined by drying a selected number of bars at 300°—600° F. (150°—315° C.), in a small gas- or oil-fired furnace.
—A. R. P.

Copper-nickel ores of the Rustenburg district (South Africa). J. A. Ortlepp. J. Chem. Met. Soc., S. Afr., 1922, 23, 23—31.

Microscopical examination and photomicrographs of polished specimens showed the ore to have been formed by magmatic differentiation, and to be composed of pyrrhotite, pentlandite, chalcopyrite, maucherite, an unidentified mineral, and a pyroxene gangue. Tests on ore containing 3·7% of nickel, 0·48% of copper, 26% of sulphur, and 39% of iron, showed that physical methods of concentration, including magnetic concentration and flotation, are unsuitable, but concentration of nickel in the form of matte is economically possible.—J. B. P.

Lead blast-furnace; Powdered coal in the ——. E. H. Hamilton. Min. and Met., Oct., 1922, 25—27.

The working of a lead blast-furnace fired by means of powdered coal fed through the tuyères has been examined, and tables are given showing the heat distribution and output of metal and matte compared with the ordinary method of working. While the new process of firing slows down the output by about 6%, a greater recovery of metal is effected, together with a slight saving of fuel.—A. R. P.

Metals; Action of nitric acid on ——, *and an example of a periodic reaction. Catalysis. XIV.* B. C. Banerji and N. R. Dhar. Z. anorg. Chem., 1922, **122**, 73—80.

The rate of solution of copper, silver, lead, nickel, brass, mint silver, and of copper-nickel alloy in nitric acid in the presence of various salts was studied. The rate was found by direct weighing of the strip of metal or alloy before and after immersion in the acid. Ferrous salts acted as catalysts in all cases; this is explained by the fact that nitrous acid is formed by the action of nitric acid on ferrous salts, and the solution of metals is accelerated by nitrous acid. Ferric salts also act as catalysts, as a result of reduction to ferrous salts by the action of such metals as copper, silver, etc. Oxidising agents, such as potassium permanganate and chlorate, act as negative catalysts, because they prevent the formation of nitrous acid. The action of nitric acid on a 50% alloy of nickel and copper takes place in reaction periods of diminishing lengths, each followed by a period of no reaction. —W. T.

Metallic bodies formed from powdery material by pressure or sintering and not previously subjected to cold work; Grain growth in ——. F. Sauerwald. Z. anorg. Chem., 1922, **122**, 277—294.

The application of pressure did not increase the size of the grains, but with increasing temperature an increase in the size of the grains was observed in the cases of iron, nickel, cobalt, tungsten, and copper. There was a limit of temperature, which could be determined within 100° C., beyond which further increase in temperature resulted in a rapid increase in the size of the grains. This limiting temperature is independent of the pressure applied in compressing the metal and has a characteristic value for each metal. Increase in the size of grains was not observed in the case of zinc and aluminium. These results are discussed in the light of Tammann's theory of crystallisation (Z. anorg. Chem., 1920, **113**, 163).—W. T.

Gold solidified from the melt; Recrystallisation of pure, mechanically unworked ——. W. Fraenkel. Z. anorg. Chem., 1922, **122**, 295—298.

Pure mechanically unworked gold showed no change in size or form of crystals on heating to 1000°—1045° C. The purity of the metal, however, was not of such a high degree that the possibility of the crystallites being surrounded by thin films of impurity is excluded (*cf.* Tammann, Z. anorg. Chem., 1920, **113**, 163).—W. T.

Silicon; Modifications of ——. *Silicon from copper silicide.* W. Manchot and H. Funk. Z. anorg. Chem., 1922, **122**, 22—26.

Specimens of silicon obtained from a copper silicide regulus were similar to those obtained from aluminium and silver reguli (*cf.* J., 1922, 251 A). Conditions which favour the formation of crystalline silicon gave a form which reacted but slowly with hydrofluoric acid. Crystalline silicon very soluble in this acid could not be obtained.—W. T.

Tungsten; Attempts to decompose —— *at high temperatures.* G. L. Wendt and C. E. Irion. J. Amer. Chem. Soc., 1922, **44**, 1887—1894.

When tungsten wires, 4 cm. long and 0·035 mm. diam., are exploded at a temperature of 20,000° C. by discharging a condenser at 30,000—45,000 volts through them (*cf.* Anderson, Astrophys. J., 1920, **51**, 37—48), either in a vacuum or in an atmosphere of carbon dioxide, the metal is entirely dissipated, no smoke, dust, or residue being found after the explosion. Abundant quantities of gas are produced, and this gives a spectrum showing the yellow helium line and several other unidentified lines but no hydrogen lines. The volume of gas unabsorbable by potassium hydroxide produced from 0·713 mg. of tungsten varied between 3·62 and 0·30 c.c. Had the tungsten been converted entirely into helium the volume of gas would have been 4·0 c.c.—J. F. S.

Hardness of solid substances. Reis and Zimmermann. *See* I.

Patents.

Puddling [iron; Furnace for and] art of ——. H. D. Hibbard. E.P. 179,888, 26.9.21. Conv., 11.5.21.

A puddling furnace consists of a cylindrical reaction vessel, lined with neutral or basic bricks, mounted on hollow trunnions, and provided with an interior longitudinal dam, a movable block, having a passage through which fuel is charged to the furnace, near to one trunnion, and a smoke stack near the other. The furnace is coupled to a reversible motor for imparting an oscillatory movement by devices that allow of exact control. The furnace is charged with pig iron and an oxidising agent, *e.g.*, ferric oxide, and the molten charge is vigorously oscillated so that it flows back and forth over the dam, thereby ensuring efficient mixing. When the iron has balled together, the first slag is tapped and a second charge of oxidising agent together with fluxes, *e.g.*, silica or fluorspar, is introduced. After tapping the second slag the ball is worked into a symmetrical form by disengaging the reversing gear of the motor and operating control levers in such a way that the ball is rolled between the dam and the discharging door.—A. R. P.

Iron deposits; Process for the production of electrolytic ——. M. Schlötter. G.P. 305,156, 4.8.17.

By using ferrous perchlorate instead of ferrous chloride as electrolyte, a deposit of iron is obtained which, even under strong magnification, shows no crystalline structure, and is therefore suitable for galvano-plastic reproductions.—A. R. P.

Steel; Method of manufacturing ——. J. C. Beneker, Assr. to F. F. McIntosh and W. B. Skinkle. U.S.P. 1,431,621, 10.10.22. Appl., 1.3.21.

Steel containing not more than 0·35% C and not less than 1% Mn is prepared by adding to a bath of molten steel covered with a slag high in manganese oxide, sufficient of a silico-manganese alloy to reduce the desired quantity of manganese from the slag while, at the same time, oxidising and slagging the silicon.—A. R. P.

Metals [e.g., iron]; Production of glossy metallic coatings [e.g., of zinc] on ——. A. Classen. E.P. 186,459, 14.7.21.

Glossy metallic coatings, which do not require polishing, may be electrolytically deposited on metals from plating baths containing organic or inorganic colloids or substances producing them, together with hydrogen peroxide or its derivatives, such as per-acids, per-salts, or organic substitution products, capable of preventing the generation of hydrogen from the cathode, and not powerful enough to decompose the colloids. Thus, a bath for galvanising iron consists of 10 kg. of zinc sulphate, 2·5 kg. of ammonium sulphate, 120 c.c. of sulphuric acid, 100—120 g. of alum, starch, albumin, or gelatin, and 120 g. of potassium persulphate per 100 l., and is operated at a current density of 5 amps. per sq. dm. at 3 volts. Deposits from this bath are characterised by a high density, brilliant istre, and great durability.—A. R. P.

opper alloys; Treatment of ——. Isabellen-Hütte Ges.m.b.H. E.P. 161,537, 9.4.21. Conv., 10.4.20.

HE mechanical properties of copper alloys containng manganese, aluminium, zinc, tin, or silicon ay be improved by annealing the alloy below red eat. The hardness and elastic limit of most copper lloys are increased by this treatment. In certain ases the alloys are heated to a temperature above 50° C., depending on the particular composition, ooled, and reheated. The presence of other metals n the alloy affects only the temperature of treatnent.—C. A. K.

opper; Process of and apparatus for precipitating —— from solutions. F. S. Adams. U.S.P. 1,430,140, 26.9.22. Appl., 20.7.20.

Sulphur dioxide is passed repeatedly through the solution to precipitate the copper.—C. A. K.

Magnesium foil; Method of manufacturing ——. W. Boehm. E.P. 186,253, 19.9.21.

The metal is heated to a temperature just below its melting point previous to rolling.—A. R. P.

Platinum and similar metals; Extraction of —— from their sands and ores. R. Thayer. U.S.P. 1,429,378, 19.9.22. Appl., 23.1.20.

Superheated steam is passed through a mass of finely-divided ore maintained at a temperature below the melting point of the constituent metals, which are recovered from the collected fume.
—C. A. K.

Alloy for repair purposes. P. O. Melton. U.S.P. 1,429,959, 26.9.22. Appl., 6.9.21.

An alloy for repair work contains Zn 11 oz., Pb 1¼ lb., Sn 1¾ lb., and Cu 1 oz.—C. A. K.

Zinc; Extraction of —— [from materials containing lead and zinc]. W. G. Waring, Assr. to G. Battelle. U.S.P. 1,430,269, 26.9.22. Appl., 17.8.21.

The process of separating zinc from materials containing lead and zinc by extraction with a hot solution of ammonium sulphate, with subsequent crystallisation of zinc sulphate, is supplemented by treating the separated zinc salt with ammonium carbonate, whereby zinc carbonate and ammonium sulphate are formed.—C. A. K.

Chloridising process and apparatus. F. S. Low, Assr. to Niagara Alkali Co. U.S.P. 1,430,454, 26.9.22. Appl., 27.12.20.

Hydrogen and chlorine are burned together in proximity to the heated material to be chloridised.
—C. A. K.

Precious metals; Cyanide process for treating ores of ——. D. L. H. Forbes. U.S.P. 1,430,635, 3.10.22. Appl., 3.4.22.

Small quantities of dry sodium peroxide are injected below the surface of a mixture of comminuted ore and cyanide solution.—A. R. M.

Vanadium; Process of recovering ——. K. B. Thews, Assr. to Colorado Vanadium Corp. U.S.P. 1,430,864, 3.10.22. Appl., 29.10.20.

Vanadium is precipitated as calcium vanadate by the addition of a soluble calcium salt to an acid solution of soluble vanadates contaminated with iron or aluminium compounds.—A. R. P.

Ores; Electric furnace for treating ——. A. Counas. U.S.P. 1,430,948, 3.10.22. Appl., 21.8.20.

An electric furnace for treating ores consists of a rectangular chamber provided with a central hopper and a series of inclined electrodes on either side thereof, together with a return electrode forming part of the hearth of the furnace and arranged directly below the hopper.—A. R. P.

Ores; Method and means for reducing —— in electric blast furnaces. E. Fornander. U.S.P. 1,430,971, 3.10.22. Appl., 14.4.22.

The furnace consists of a reducing shaft opening out at the bottom into a melting chamber with a conical hearth. The ore and fluxes are charged into the shaft and gradually descend into the chamber, where a supply of reducing material is introduced in such a way that it forms a covering layer on the sloping walls of the chamber and leaves a free space between itself and the roof. A portion of the gases evolved from the reduction is removed from the shaft and pumped back through the reducing layer into the heart of the charge, which is maintained at a suitable temperature by means of an arc.—A. R. P.

Tungsten ores; Method of treating tin-bearing ——. F. M. Becket, Assr. to Electro Metallurgical Co. U.S.P. 1,431,559, 10.10.22. Appl., 26.5.20.

Tin-bearing wolframite ores are ground and roasted, and treated with an alkaline solvent to extract the tungsten as alkali tungstate.—A. R. P.

Alloy. J. O. Whiteley, Assr. to The Dentists' Supply Co. U.S.P. 1,431,713, 10.10.22. Appl., 29.6.20.

A gold-platinum alloy containing 20—35% Au is claimed.—A. R. P.

Metals; Process for the separation and purification of —— by treatment with gases. L. Schertel and H. Arnold. G.P. 357,448, 31.5.19.

The molten metal mixture is treated with gases or vapours that form salt-like compounds with one of the metals, the quantity of gas or vapour used being in stoichiometric relation to the amount of that metal present. The charge is kept at a sufficiently high temperature to melt the salt formed, which then acts as a protective coating to the metal from the excess of gas. In this way a very complete purification is effected without serious loss of metal.
—A. R. P.

Ferrochromium alloys; Manufacture of ——. W. B. Ballantine. U.S.P. 1,430,878, 3.10.22. Appl., 2.2.22.

See E.P. 179,992 of 1921; J., 1922, 554 A.

Copper; Process for obtaining the —— from lyes resulting from the treatment of cupriferous pyrites. H. P. Soulie-Cottineau. U.S.P. 1,431,130, 3.10.22. Appl., 5.4.20.

See E.P. 141,290 of 1919; J., 1920, 414 A.

Metals; Coating of —— with metals of a lower fusing point. H. G. Grinlinton. U.S.P. 1,431,395, 10.10.22. Appl., 14.6.20.

See E.P. 146,830 of 1920; J., 1921, 776 A.

Ores or the like; Smelting ——. L. H. Diehl. U.S.P. 1,431,877, 10.10.22. Appl., 6.8.20.

See E.P. 170,100 of 1920; J., 1921, 854 A.

Steel ingots and method of and apparatus for producing [casting] same. Valley Mould and Iron Corp., Assees. of J. E. Perry. E.P. 171,352, 18.3.21. Conv., 11.11.20.

XI.—ELECTRO-CHEMISTRY.

PATENTS.

Electric gas-generator. R. Rosner. U.S.P. 1,390,646, 13.9.21. Appl., 28.1.21.

THE patent relates principally to means for regulating the admission of air to the apparatus described in U.S.P. 1,374,237 (J., 1922, 380 A).

Promoting chemical reactions between gases; Method of and apparatus for ——. S. Ruben. U.S.P. 1,431,047, 3.10.22. Appl., 16.4.20.

A HIGH-FREQUENCY current is passed through a conducting liquid in which the reacting gases are brought into contact with one another.—J. S. G. T.

[Electric induction] furnace linings; Method of preparing ——. M. Unger, Assr. to General Electric Co. U.S.P. 1,429,909, 19.9.22. Appl., 13.10.20.

AN induction furnace is started by placing in the heating space a number of closed conductors, melting respectively at different temperatures. A heating current is then induced therein of sufficient power to melt the conductors successively.
—T. A. S.

Electric furnace. E. A. Hauff, Assr. to Pittsburgh Engineering Works. U.S.P. 1,430,987, 3.10.22. Appl., 27.3.20.

THE electrically-conducting bottom of an electric furnace is connected with one end of the secondary winding of a transformer. A switch is arranged to connect selectively any one of a number of tappings on the secondary winding with an arcing electrode in circuit with an adjustable reactance.
—J. S. G. T.

Electric furnace. I. Rennerfelt. U.S.P. 1,431,424, 10.10.22. Appl., 10.8.21.

AN electrode projects downwards from the furnace roof so that its end is close to a mass of carbonaceous powder placed upon a central hearth, which is surrounded by a rotary annular hearth.—J. S. G. T.

Electric resistance heater. H. G. Lemoine. U.S.P. 1,431,825, 10.10.22. Appl., 18.7.21.

A METAL of the tungsten group is embedded in a refractory mass consisting of a mixture of an oxide of the zirconium group and magnesia.—J. S. G. T.

Dry cells; Manufacture of ——. H. de Olaneta, Assr. to Winchester Repeating Arms Co. U.S.P. 1,430,726, 3.10.22. Appl., 24.2.20.

RECOVERED manganese dioxide employed as the depolariser in a primary cell is leached with a neutral solution of the electrolyte used in the cell, prior to assembling the cell.—J. S. G. T.

Electrolytic cell. E. A. Le Sueur. U.S.P. 1,431,014, 3.10.22. Appl., 23.10.20.

THE bottom of an electrolytic cell, serving as cathode, is provided with one or more conducting projections which may take the form of annuli surrounding the anode.—B. M. V.

Agitating apparatus for tanks [for electrolytic cells]. T. H. Mumford, jun. U.S.P. 1,431,022, 3.10.22. Appl., 2.3.21.

THE electrolyte is delivered under pressure through openings or jets in pipes which can be reciprocated within the tank or cell.—B. M. V.

Electrolytic apparatus. H. Y. Eagle. U.S.P. 1,431,574, 10.10.22. Appl., 12.11.20.

ELECTROLYTE flows continuously through a tank in which a number of groups of electrodes, each comprising anodes and cathodes, is arranged, each group of anodes receiving current from a different conductor.—J. S. G. T.

Electrolysis; Art of ——. C. G. Spencer. U.S.P. 1,431,602, 10.10.22. Appl., 15.1.21.

THE intake of a gas washer is connected with an electrolyser, and porous mineral matter is interposed between the intake and outlet of the washer.

XII.—FATS; OILS; WAXES.

Oils and fats from the seeds of Indian forest tree M. G. Rau and J. L. Simonsen. Indian Fore Records, 1922, **9**. Part III. 15 pages.

THE seeds of *Chloroxylon Swietenia* yield 16% of non-drying oil consisting of glycerides of steari palmitic, myristic, oleic, and linolenic acids. The seeds of *Calophyllum Wightianum* yield 34% of an oil closely resembling that obtained from the seeds of *C. inophyllum*, and containing about 10% of resin, and glycerides of stearic, palmitic, oleic, and linolic acids. The seeds of *Mimusops Elengi* yielded 16% of oil consisting of glycerides of stearic, palmitic, and oleic acids, and of an unidentified saturated acid which was possibly behenic acid. The seeds of *Shorea robusta* yield 16·4% of a fat resembling Borneo tallow and consisting of glycerides of stearic and oleic acids. *Garcinia Cambogia* seeds yield 31% of a fat resembling the fats from the other species of *Garcinia*, which should prove an excellent edible fat. It consists of glycerides of stearic and oleic acids.—H. C. R.

Liver oil; Sulphuric acid reaction for ——. H. D. Richmond and E. H. England. Analyst, 1922, **47**, 431.

CONSTANT results were obtained in testing cod liver oil by the dilution method (Drummond and Watson, J., 1922, 718 A) by adding 1 c.c. of the cod liver oil to 10 c.c. of liquid paraffin B.P., mixing, and transferring 10 drops of this to a white porcelain basin, adding 1 drop of sulphuric acid (B.P.) and stirring with a glass rod. If a transient purplish colour developed, liquid paraffin was added in successive quantities of 5 c.c. until no purple colour was given, and the dilution at which a faint transient purple colour was seen was recorded. If no purple was seen, successive additions of 1 c.c., 1 c.c., 2 c.c., and 5 c.c. of cod liver oil were made. The authors were unable to obtain good results when instead of liquid paraffin petroleum spirit was used, as recommended by Drummond and Watson.—H. C. R.

Copper; Action of —— in promoting the activity of nickel catalyst [*in hydrogenation of oils*]. E. F. Armstrong and T. P. Hilditch. Proc. Roy. Soc., 1922, A 102, 27—32.

A copper-nickel catalyst may be produced in hydrogen when mixed compounds of copper and nickel distributed on suitable carriers are heated to 180° C., whereas nickel compounds alone under such conditions are not reduced by hydrogen below 300° C. and not rapidly below 350°—400° C. For the reduction of nickel at this low temperature an intimate mixture of the copper and nickel compounds must be used, which must be more intimate than can be obtained by mechanical mixing. Coprecipitation is not always sufficient to obtain the desired degree of intimacy, for a comparison of the activity of the catalysts with the nature of the nickel cupric carbonates from which they are produced shows that both the nickel and the copper must be in the same complex molecule to obtain any marked degree of catalytic activity. It is suggested hat the necessary local heat to provide a sufficiently high temperature for the reduction of the nickel is urnished by the reduction of the copper, provided he latter is in sufficiently close proximity to the nickel.—J. F. S.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Reflection factors of industrial paints and pigments. H. A. Gardner. Circ. 133, U.S. Paint Manufacturers' Assoc., Sept., 1921. 8 pp. (*Cf.* J., 1916, 263.)

The previously recorded figure of 0·88 for the reflecting power of the magnesium carbonate adopted as a standard has been found to be low, recent measurement having given a value of 0·98. Examination of some panels of tinted and shaded flat wall lithopone paints after storage for five years in the dark showed no falling off in reflecting power in the case of light green, yellow, and terra-cotta tints, and an increase in the case of light buff; light cream, light pink, and light blue had suffered 6% loss, but dark blue and dark green had lost 30% of their original values. Very little loss also was recorded on certain industrial white paints, any loss being attributed to the well-known yellowing which develops on storage in the dark. Light and medium grey paints showed an increase in reflecting value attributed to slight fading of the tints. Among modern industrial white paints examined in May, 1921, one specimen showed a reflecting value of 82%, calculated on the corrected basis, thus showing a marked improvement on commercial paints of earlier manufacture. A laboratory method of obtaining comparative reflecting powers consists in applying two coats of constant weight of flat paint of uniform composition to white bond paper, the medium used being an ethyl acetate solution of nitrocellulose plasticised with castor oil. When such paints are applied to glass plates in place of paper and the coatings are viewed on black and white backgrounds respectively, figures are obtained showing both reflecting values and relative opacities. The coefficient of reflection modified by the relative opacity is obtained by applying flat oil paints to iron panels previously coated with a flat black having a very low reflecting power. Such examination shows transparent pigments to possess very low coefficients of reflection. Very small differences in reflecting power between various pigments are shown when the dry compressed powders are examined. When various commercial pigments are examined for brightness by the Pfund colorimeter, zinc oxide heads the scale with a relative brightness of 92·5 as compared with two grades of white lead having values of 80·7 and 60·5 respectively.—A. de W.

Fire-resisting paints and varnishes. H. A. Gardner. Circ. 121, U.S. Paint Manufacturers' Assoc., April, 1921. 2 pp.

The use of ammonium phosphate in large proportion as a constituent of fire-resisting paints for exterior work is not recommended on account of its solubility in water. Addition of 5% of ammonium phosphate to varnishes, although productive of a somewhat sandy film, is suggested in view of the transparency of this material in varnish. Zinc borate, which fuses to a glass-like sealing film under the action of heat, is likely to prove of use as a constituent of fire-resisting paint. —A. de W.

Paint and varnish; Physical testing of ——. H. A. Gardner. Circ. 122, U.S. Paint Manufacturers' Assoc., April, 1922. 13 pp.

The behaviour of varnish and paint films on bending and exposure to the weather may be conveniently determined by applying the coating under test to a sheet of high-grade bond paper previously rendered impermeable, if necessary, by coating with paraffin or parchmentising. Other tests include the determination of the bursting strain, tensile strength, resistance to bending, elongation, etc., before and after exposure, the figure for the uncoated paper being also determined. The hiding power of liquid paints is most conveniently determined by the Pfund cryptometer (J., 1920, 34 a), but the author has devised a simpler form of the apparatus in which the critical thickness of complete obscuration is read on a broad longitudinal band etched on the upper surface of the base plate. Rough comparisons of hiding power of liquid or dry paint films can be made by applying these over a sheet of bond paper on which are printed squares of black, dark grey, light grey, etc., and comparing with a standard. The behaviour of varnishes under different conditions of application on ageing can be observed by coating on paper sheets printed with square blocks of red, yellow, etc., exposures being made in the open or in the rays of a mercury arc lamp.—A. de W.

Pfund paint gauge; Discussion of the ——. H. A. Gardner and P. C. Holdt. Circ. 132, U.S. Paint Manufacturers' Assoc., Aug., 1921. 4 pp.

The spreading rate of paints as determined from the figure obtained for the thickness of wet paint films measured by the Pfund paint gauge (J., 1921, 356 a) agreed to within 3·5% with that obtained by weighing the paint coating in a test when finely-ground paint was applied to a smooth surface (glass). In spreading tests (both hand brushing and spraying) on clean black iron and on dressed timber that had been primed, and measurements by the Pfund instrument, although fairly close agreement was obtained in the repeat determinations of thickness by the gauge, the agreement between the spreading rate thus determined and that determined by weighing the paint leaves the value of the instrument as a check on actual practice open to considerable criticism.—A. de W.

White and tinted paints; Storage conditions in —— with reference to soap formation. H. A. Gardner. Circ. 143, U.S. Paint Manufacturers' Assoc., Jan., 1922. 19 pp.

The formation of granular or flaky soap in lead-zinc paints which have been stored for 3—5 years manifests itself as the separation of a soft, granular, or sometimes firm, shell-like mass at the junction of settled pigment and medium, or sometimes distributed throughout the settled pigment or adhering to the sides of the can. The soap usually contains 88% of organic matter, the metal consisting of about 85% of zinc and 15% of lead. The effect upon the paint is to give a gritty appearance to the coating after application. The formation of such soaps appears to be entirely due to interaction between basic lead or zinc pigments and an acid constituent of the medium, zinc pigments being more fruitful in forming separated soaps owing to their lesser solubility. Whilst raw linseed oil with an acid value not exceeding 5 does not promote any marked soap formation, the hydrolysing effect of "foots," causing as it does development of free fatty acid, stimulates the reaction, as also does water containing an ionisable salt or emulsifying liquid. Acid refined linseed oil (acid value 8—10), and media containing small amounts of rosin are very productive of the formation of soap granules with basic pigments, but high percentages of free fatty acids or large proportions of rosin, although liable to "liver" basic pigments, exert such a powerful solvent action on heavy metal soaps that precipitation does not take place. Similarly, while petroleum spirit as a thinner favours the separation of granular soap on account of its poor solvent power, pine oil and coal tar solvents prevent precipitation. Paints showing soap formation may sometimes be made satisfactory by straining out the separated soap or re-grinding. Tables are appended showing the results of examination of stored paints for soap formation together with their composition.
—A. de W.

Paint and varnish films; Speed of evaporation of thinners from ——. H. A. Gardner, P. C. Holdt, and E. Bielouss. Circ. 141, U.S. Paint Manufacturers' Assoc., Dec., 1921. 16 pp.

From a series of experiments in which two types of varnish ("short" and "long") and both gloss and flat paints were thinned with different varieties of volatile solvents, *e.g.*, turpentine, mineral hydrocarbons of varying boiling-points, coal-tar naphtha, etc., and films therefrom weighed every 15 mins., it is shown that the rate of evaporation is inversely proportional to boiling-point and independent of the type of hydrocarbon. The hygrometric state of the surrounding atmosphere has no influence on the rate of evaporation from either paint or varnish films, excepting in the extreme case of a possible deposition of dew on the film. The highest viscosity of the finished product is obtained by the use of turpentine, petroleum hydrocarbons giving the lowest values, roughly proportional to their boiling-points. This is attributed to turpentine and solvent naphtha merely acting as diluents without effecting any changes in dispersity of the varnish medium, whilst petroleum hydrocarbons produce an alteration in structure by causing coalescence.—A. de W.

Japanese tung oil. H. A. Gardner and A. Reilly. Circ. 138, U.S. Paint Manufacturers' Assoc., Nov., 1921. 7 pp.

The seed of the Japanese tung tree (*Aleurites cordata*) is smaller than that of the Chinese variety (*A. fordii*) and is claimed in Japan to yield an oil which does not gelatinise on heating. The seed when shelled yielded 63% of pulp, from which 51% of a light golden yellow oil was obtained by extraction, the residue being a dry white powder of high nitrogen content. The oil had the following characters: iodine value (Wijs) 150·2, (Hübl) 154·4; saponif. value 193·2; acid value 0·9; sp. gr. at 15·5°/15·5° C., 0·9342; n_D^{25}=1·4981. Under the A.S.T.M. standardised heat test for tung oil, the oil yielded a viscous liquid in one hour. The viscosity was intermediate between that of Chinese tung oil and raw linseed oil. On exposure to the air, the oil yielded an opaque soft film in 43 hrs., whilst with 10% of lead-manganese drier, it dried in 10 hrs. Oils which had been blown at 150° C. and at 200° C. for 5 hrs., and then thinned with an equal volume of mineral spirit, dried in 34 and 81 hrs. respectively, an opaque film being formed in each case. On heating the oil for one hr. to 315·5° C., the colour of the oil became pale yellow, the acid value 0·8, the sp. gr. 0·964, and the viscosity 78 poises (original oil 1·25 poises), whilst drying took 80 hrs. On heating another sample to the same temperature for 20 mins. and thereafter maintaining at 250° C. for a further 2 hrs., the colour was observed to darken after one hour, whilst after 2 hours the oil was slightly darker than the original oil, had a viscosity exceeding 78 poises, acid value 0·6, and sp. gr. 0·975. Without a drier the oil dried to a clear film in 43 hrs., whilst with the addition of 10% of lead-manganese drier it dried hard and clear in 10 hrs. This latter heat treatment is interesting in that it was the only one of the series yielding an oil which gave a clear film without driers and that the time of drying compared favourably with that of heavy bodied linseed oil (58 hrs.).—A. de W.

Fatty oils; Drying of ——. P. Slansky. Z. angew. Chem., 1922, 35, 389—391.

The drying of linseed oil is due to oxidation and gelatinisation (*cf.* J., 1921, 817 A), the latter being accelerated by increase of temperature. Linseed oil fatty acids absorb oxygen more rapidly than does linseed oil itself, and the rate of oxidation of the oil is increased by the addition of linolic or linolenic acid; gelatinisation, which is caused by coagulation of the oxidised glycerides, is increased by the addition of oleic acid to the oil. Linoxyn, the solid substance produced by the drying of linseed oil, is capable of absorbing 15% of its weight of water.
—W. P. S.

Dekalin; Properties and composition of ——. J. B. Coleman and P. Bilham. Chem. Age, 1922, 7, 554—555.

An investigation of the physical and chemical properties of dekalin was undertaken in order to determine its suitability as a turpentine substitute. Dekalin has the following physical characters:—sp. gr. at 20° C. 0·8947, n_D^{20}=1·4815, flash point 51·6° C., viscosity at 40° C. (100η)=0·675, b.p. 180°—197° C., relative rate of evaporation compared with American turpentine 1:2·89, percentage residue on evaporation 0·001935, compared with 0·1516 for turpentine. Chemically dekalin consists primarily of a mixture of tetrahydronaphthalene 20%, and decahydronaphthalene 80%. On treatment with fuming sulphuric acid the tetrahydronaphthalene is absorbed, and the residual oil is almost pure decahydro-compound. On oxidation of dekalin with permanganate the deca-compound was unattacked and the presence of the tetrahydro-compound was proved by the formation and isolation of *o*-carboxyhydrocinnamic acid. The presence of the tetrahydro-compound accounts for the oxygen-carrying properties of dekalin, which may be demonstrated by shaking a dekalin-water emulsion with an acidified solution of potassium iodide, iodine being immediately liberated. The high flash point of dekalin as compared with turpentine enables higher temperatures to be employed in varnish making; the viscosity indicates a superior thinning power. The high boiling point prohibits its use for quick-drying varnishes, but for paints and slow-drying varnishes it is no disadvantage, as the drying action continues all the time the dekalin is evaporating owing to its oxygen-carrying properties.—G. F. M.

Varnish; Measurement of the consistency of ——. H. A. Gardner and P. C. Holdt. Circ. 127, U.S. Paint Manufacturers' Assoc., June, 1921. 51 pp.

A general introduction to the principles underlying viscometry is given, and the development of the measurement of plasticity of plastic solids as investigated by Bingham and his co-workers (J., 1920, 292 B, 495 A) is described. The various types of viscometers, *i.e.*, air-bubble, falling sphere, torsional, and efflux, are described, and the accuracy of the results therefrom is discussed. A very full resumé of the subject matter of Bingham's papers on the use of the plastometer is given and its applicability to the study of possible plasticity in varnishes is considered. An investigation undertaken to show a possible connexion between viscosity and durability of varnishes gave a negative result. The authors conclude that the plastometer and the MacMichael and Doolittle torsional viscometers are the only reliable instruments for determining viscosities of varnishes, the first-mentioned instrument possessing the advantage of higher accuracy and greater ease in furnishing absolute results.—A. de W.

Varnish; Standardised apparatus for determining the consistency of —— by the air-bubble test. H. A. Gardner and P. C. Holdt. Circ. 128, U.S. Paint Manufacturers' Assoc., June, 1921. 7 pp.

Twenty tubes (110 mm. long by 13·3±0·05 mm. diam.) are filled with various mixtures of mineral oils free from fatty oils giving a range of absolute viscosities from 0·50 to 5·50 poises at 25° C., care being taken that an air bubble of uniform size is left in each tube. The closed tubes are mounted in a case and serve as standards to give a fairly rough but rapid determination of viscosity of any varnish which is similarly filled into a tube of the same dimensions as the standard tubes.—A. de W.

Bordeaux turpentine. Dupont. *See* XX.

Patents.

White lead; Manufacture of ——. A. E. White. From National Lead Co. E.P. 186,114, 14.6.21.

An apparatus for the continuous manufacture of white lead from granular metallic lead comprises a rotary horizontal chamber, about 96 ft. long and 6 ft. in diam., constructed of heat-insulating material, *e.g.*, wooden staves lined with stout paper and faced internally with match-boards. The chamber is fitted at one end with an inlet pipe and hopper for granular lead and an inlet for a gaseous reagent, and at the other end with an extension of reduced diameter, to which the corroded lead is transferred by means of vanes. This extension is provided with a reticulate or lattice-work end portion to prevent the discharge of lumps therefrom. A conveyor is provided under the extension, the latter being housed in an enclosure connected to devices for maintaining a reduced pressure within the chamber. The granular lead is fed into the chamber at a rate controlled by the rotation of the latter, and the inlet pipe for the metallic lead is so constructed that its surface temperature is maintained above the dew point of the gases in the chamber in order to avoid collection of masses of wet metallic lead. The corroding mass in its passage through the chamber is maintained at a moisture content between 2% and 5% by spraying with regulated quantities of a liquid reagent (acetic acid and water) at intervals along the chamber by non-axial nozzles projecting inwards from the chamber wall to a degree exceeding the depth of the tumbling mass of material and so arranged that the lead is sprayed without wetting the chamber wall; the spraying nozzles are automatically supplied by the rotation of the chamber and their surface temperature is maintained above the dew point of the gases in the chamber.—A. de W.

Magnesium oxychloride cements; [Paint for use in] laying of —— on metallic surfaces. J. Davies and W. H. Miles. E.P. 186,231, 24.8.21.

A paint for coating metallic surfaces before the application of magnesium oxychloride cement is prepared by mixing equal parts of powdered fluorspar, whiting, and china clay, with 1·8 times (by weight) of a solution of sodium silicate of 33° B. (sp. gr. 1·296). A hard coating is formed which is quick-drying and not liable to crack.—J. B. P.

Resins; Production of artificial ——. R. Pummerer. E.P. 165,408, 22.6.21. Conv., 25.6.20.

By moderated oxidation of phenol or its homologues with alkaline potassium ferricyanide solution, with glacial acetic acid and lead dioxide, or with ferric chloride, substances of higher molecular weight are obtained exhibiting the properties of artificial resins. Treatment with alkalis or acids, or heating causes polymerisation of these primary products and makes them partially soluble in alkalis. The colour of the products can be improved by reduction and also by acylation. Acylation or alkylation also renders them insoluble in alkali.—D. F. T.

Resins; Manufacture of ——. O. Y. Imray. From Soc. of Chem. Ind. in Basle. E.P. 186,107, 9.6.21.

An aromatic hydroxy-compound, such as phenol, resorcinol, cresol, or naphthol, is heated with sulphur in the presence of a basic substance in a proportion of not more than one-fifth of that necessary for the neutralisation of the hydroxy-compound. The end of the reaction is indicated by the cessation of evolution of hydrogen sulphide. A suitable proportion of sulphur is 2—3 atoms per molecule of phenolic compound. As catalyst a halogen, *e.g.*, iodine, may be employed. The addition of a small proportion of formaldehyde or of some compound yielding this substance is advantageous. The products are light-coloured resinous substances, obtainable in a fusible and soluble condition but convertible, by heat under pressure, into a hard infusible condition.—D. F. T.

Coating compositions; Manufacture of ——. *Manufacture of plastic material for flooring and other purposes.* Imperial Trust for the Encouragement of Scientific and Industrial Research, and S. B. Schryver. E.P. (A) 186,156 and (B) 186,157, 21.6.21.

(A) The proteins separated from castor beans or other oil seeds (*cf.* E.P. 140,911; J., 1920, 419 A) when mixed with alkalis or alkali carbonates, or with combinations generating these, together with slaked lime or magnesia, yield cement-forming materials. These on admixture with alkali-resistant pigments form powders which on treatment with water become successively gelatinous and semifluid. In the latter condition the products can be applied as distemper. (B) The isolated proteins or the whole residues of the oleaginous seeds are mixed with an alkali and alkaline earth as in (A), but filling material is then introduced, *e.g.*, powdered slate, sawdust, or asbestos powder. Plastic products are obtained from this dry material by mixing with water to a paste and allowing to dry slowly or by moistening with water and subjecting to pressure. —D. F. T.

Paint composition. Mineral oil [composition]. W. N. Blakeman. U.S.P. (A) 1,430,881, and (B) 1,430,882, 3.10.22. Appl., 16.4.21.

(A) A PAINT composition comprises tung oil, a non-drying fatty oil, a mineral oil of the Pennsylvania type, hydrogenated and oxidised, and a pigment. (B) An oil vehicle comprises tung oil, a non-drying oil, and a hydrogenated and oxidised mineral oil of the Pennsylvania type.—L. A. C.

Pigment oil composition; Method of preparing ——. Method of preparing varnishes. [Colour] lake and method of preparing same. G. W. Acheson, Assr. to Acheson Corp. U.S.P. (A) 1,431,079, (B) 1,431,080, and (C) 1,431,081, 3.10.22. Appl., 7.8.22.

(A) AN emulsion of an oil and dilute ammonia solution containing a deflocculated pigment in suspension is treated with an electrolyte to precipitate the oil and pigment together as a curd, which is separated from the aqueous liquor and dried. (B) Varnish stock containing pigment material is prepared by precipitating simultaneously resinous, oily, and pigment components by the addition of an electrolyte to a mixture containing a colloidal suspension of a resin, an emulsified oil, and a deflocculated pigment, and separating the precipitate from excess water. (C) A lake comprising reflocculated clay particles carrying an adsorbed dyestuff is prepared by deflocculating clay material, separating the finer particles, and subsequently reflocculating the material in the presence of a dyestuff.—L. A. C.

Green chromium oxide. U.S.P. 1,429,912. *See* VII.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Lampblack in rubber mixings. E. Marckwald and F. Frank. Gummi-Zeit., 1922, 36, 1459—1462, 37, 5—8.

A COMPARISON of several grades of German lampblack with a sample of gas black from America, showed that the latter gave vulcanised mixings with higher breaking strength and elongation, but that the former yielded products with a higher degree of elasticity or resilience. A mixture of rubber (55), lampblack or gas black (25), sulphur (5), litharge (5), and zinc oxide (10) was found particularly useful for revealing the differences; comparative experiments with this type of mixture also demonstrated the greater resistance to tearing and lower resistance to destruction by repeated application of a load, imparted by gas black. Microscopical examination of the samples of lampblack and gas black revealed their very fine state of division but did not supply any satisfactory explanation of the difference in their specific characteristics when embodied in vulcanised rubber.—D. F. T.

PATENTS.

Hydrocarbon [vulcanisable] product and process of making same. H. H. Culmer. U.S.P. 1,430,538, 3.10.22. Appl., 1.3.17.

OLEFINE hydrocarbons are treated with ozone at a temperature below that at which the hydrocarbons distil, until a solid or semi-solid, elastic product capable of vulcanisation is obtained.—L. A. C.

Binding and waterproofing material; Plastic —— and process of making the same. H. E. Brown and J. H. Stover, Assrs. to Sona Corp. U.S.P. 1,431,455, 10.10.22. Appl., 24.6.21.

A BINDING and waterproofing material comprises a natural vulcanisable gum combined with sufficient cellulose xanthate to furnish the necessary sulphur to secure the desired degree of vulcanisation in the finished product, and inorganic or organic filling material.—L. A. C.

Rubber articles; Process for the manufacture of —— [by moulding rubber gel]. F. C. Jones. E.P. 186,691, 1.7.21, 17.8.21, and 7.11.21.

XV.—LEATHER; BONE; HORN; GLUE.

Tannins and similar compounds. X. Tannin of the German oak. K. Freudenberg and E. Vollbrecht. Ber., 1922, 55, 2420—2423.

THE tannin of the oak, isolated from the fresh leaves by means of the lead salt, is purified from free ellagic acid and admixed quercetin glucosides by vacuum extraction with ethyl acetate; it is accompanied by its own condensation products from which it is freed by fractional precipitation from its alcoholic solution with ether. It is an amorphous, reddish-yellow, acidic material, $[\alpha]_D$ about −35°, freely soluble in water, alcohol, and acetone. It contains 23—25% of combined ellagic acid and 5% of combined dextrose; the remainder of the molecule in an amorphous acid, designated quercussic acid. Hydrolysis of the tannin by acids and alkalis indicates that it is a glucoside of quercussic acid which is esterified to a depside with ellagic acid. Hydrolysis in acid or alkaline solution is accompanied by considerable destruction of quercussic acid, but the latter can be liberated slowly but uniformly from the tannin by means of tannase. It resembles the original material closely in its physical properties but is optically inactive and not hydrolysed by acid or alkali. It appears to be a dibasic acid of molecular weight about 800. The preparation of the acid is rendered comparatively easy by the observations that under definite conditions *Aspergillus niger* grows on the tannin solutions and thereby completes the degradation without destroying the quercussic acid and that the galls of *Quercus pedunculata* contain the same tannin as the leaves. Fusion of the acid with potassium hydroxide has not led to the isolation of definite products. Phloroglucinol is not formed; its isolation by earlier workers from oak tannin is probably attributable to the presence of quercetin.—H. W.

Tannins and similar substances. XI. Chinese tannin. K. Freudenberg and W. Scilasi. Ber., 1922, 55, 2813—2816.

DOUBTS as to the homogeneity of Chinese tannin have been strengthened by the observation of Iljin (J., 1914, 431) that it can be separated by repeated precipitation with zinc acetate into fractions having $[\alpha]_D = +137{\cdot}85°$ and $+5{\cdot}16°$ in aqueous solution. A repetition of Iljin's experiments with commercial tannin and with a specimen isolated by the authors from Chinese galls has confirmed the accuracy of his observations but has also shown that the specific rotations of the various fractions, although differing so widely in aqueous solution, are identical when the products are dissolved in formamide, acetone, alcohol, glacial acetic acid, or pyridine. The apparent anomaly is due to the fact that tannin forms a colloidal solution only in water, in which therefore the magnitude of the specific rotation depends greatly on the degree of dispersion of the particles; this is greatly influenced by the presence of minute quantities of impurity which are gradually removed by precipitation in Iljin's experiments and can also be coagulated and rendered insoluble in ethyl acetate by heating the tannin at 100° C. Chinese tannin may be regarded as fundamentally homogeneous. Highly active specimens of the tannin are prepared by extracting the galls with cold water, neutralising the extract with sodium carbonate, and treating it with ethyl acetate. The product obtained after removal of the solvent has $[\alpha]_D = +90°$ in aqueous solution and the specific rotation is nearly independent of the concentration. A more active product cannot be obtained by means of inorganic adsorbents (kaolin etc.) or organic precipitants (starch, albumin, casein). If, however, the substance is dried in a vacuum at 100° C. and treated subsequently with anhydrous ethyl acetate, a small amount of highly coloured impurity remains undissolved and the activity of the dissolved tannin is increased to +116° in aqueous solution (1%). Two further treatments in the same manner give a product which is completely soluble in ethyl acetate and has the constant specific rotation, $[\alpha]_D = +138°$, in aqueous solution (1·5%).—H. W.

Tannase; A new —— from Aspergillus Luchuensis, Inui. M. Nierenstein. Biochem. J., 1922, **16**, 514—515.

Paullinia tannin (from the seeds of *Paullinia cupana*, H.B. and K.; *cf.* J., 1922, 184 A) is not hydrolysed by tannase prepared by growing *Aspergillus Luchuensis* in a solution of gallotannin, although the latter is hydrolysed by this enzyme. Apparently the hydrolysing properties of tannase depend on the medium in which the fungus by which it is produced is grown, for when *Aspergillus Luchuensis* is grown in a medium containing catechutannin from cube-gambia (*Ourouporia Gambier*, Baill) a new tannase is obtained which hydrolyses paullinia tannin but not gallotannin. The two tannases are named gallotannase and catechutannase respectively.—E. S.

Sundri bark; Determination of optimum temperature for maximum extraction of tannin from ——. B. B. Dhavale and S. R. Das. J. Soc. Leather Trades' Chem., 1922, **6**, 311—315.

The optimum temperature for the maximum extraction of tannin from sundri (*Heritiera minor*) bark "of official size" is 65°—70° C.—D. W.

Tannin test; A qualitative ——. E. Atkinson and E. O. Hazleton. Biochem. J., 1922, **16**, 516—517.

A piece of gold-beater's skin is pinned on a surface of paraffin wax, soaked in water, and then covered with an aqueous extract of the material to be tested. After about 15 mins. it is washed, treated with a 1% solution of ferric chloride, and again washed. If the skin is stained, the presence of tannin is indicated.—E. S.

Synthetic tannins; Notes on ——. U. J. Thuau and A. T. Hough. J. Soc. Leather Trades' Chem., 1922, **6**, 308—311.

Synthetic tannins act as accelerators of tanning by vegetable tannins; they produce a softer grain, tan the pelt and thus economise vegetable tannins. They may be used to clarify vegetable tanning materials, exerting a decolorising action and preventing fermentation and mould formation. They may also be used for preliminary tanning before tanning with vegetable tannins, chrome, alum, etc. Their properties are due to the colloidal nature and to their power of peptising. They peptise insoluble tannins, they transform non-tans and phlobaphenes into tannins, and they combine with the tannin in tanning extracts forming a more soluble tannin complex.—D. W.

Chrome tanning. Properties of the common chrome [tanning] liquors. D. Burton, R. P. Wood, and A. Glover. J. Soc. Leather Trades' Chem., 1922, **6**, 281—287.

Chrome tanning liquors prepared by the reduction of bichromate with glucose, sulphur dioxide, and sawdust, give no precipitate on dilution; a liquor reduced with spent tan is not so bright; bichromate reduced with whey does not remain clear and bright when diluted, and it gives precipitates after standing overnight. A neutralised chrome alum liquor remains bright on dilution, but it is the least stable on boiling. The amount of alkali required to give a precipitate with a measured quantity of each liquor increases with the age of a solution of bichromate reduced with sulphur dioxide and of neutralised chrome alum liquors, and decreases with the age in the case of liquors reduced with glucose, sawdust, spent tan, and whey. The amount of alkali required to produce a precipitate with the liquors at equilibrium falls in the following order: Reduced with glucose, with sulphur dioxide, with sawdust, with spent tan, with whey; neutralised chrome alum. Probably more of the chromium exists in a negatively charged form in the glucose and sulphur dioxide liquors than in the other liquors. Applying the law of mass action to the equilibrium, the amount of negatively charged chromium compound will be decreased if the hydrion concentration of the solution be increased by the addition of acid and increased if the hydrion concentration be decreased by the addition of alkali.—D. W.

Leather analysis; Simple apparatus for the extraction of water-soluble matter from leather, and notes on ——. A. T. Hough. J. Soc. Leather Trades' Chem., 1922, **6**, 302—307.

Five grams of the leather is placed in a Gooch crucible, closed by a porous plate and suspended in the bottom of a cylinder containing 250 c.c. of distilled water at 15°—25° C. After ½ hr. the leather is raised 3—4 cm., and again three times in 1½ hrs. It is finally raised to just below the surface of the water, left overnight, and 50—100 c.c. of the liquid is evaporated to dryness and the residue weighed to obtain the water-soluble matter. In determining the soluble ash the dry water-soluble matter should be treated with sulphuric acid, the excess driven off by ignition, and the sulphated residue weighed and reported as such. The figure obtained is larger than the soluble ash, and more correctly represents the soluble mineral matter.—D. W.

Leather; Influence of atmospheric humidity on strength and stretch of ——. F. P. Veitch, R. W. Frey, and L. R. Leinbach. J. Amer. Leather Chem. Assoc., 1922, **17**, 492—508.

The tensile strength and stretch of lightly tanned unloaded, and unstuffed leather was determined on a series of test pieces under conditions of different atmospheric humidity. An increase of relative humidity from 35% to 55% caused an increase of 12·9% in the tensile strength, 15·7% in the stretch, and 1·9% in the moisture content. An increase from 35% to 75% relative humidity caused an increase of 42·3% in tensile strength, 53·1% in stretch, and 8·2% in the moisture content. The increase in strength is not proportional to the increase in relative humidity, but would seem to be directly related to the moisture content of the leather. This confirms the results of Rudeloff (J., 1904, 992) and Roys (Hide and Leather, Jan. 1, 1921, 21), who found that the effect of a change in the relative humidity is greater at high than at low humidities.—D. W.

Gelatin; Some properties of dialysed ——. D. J. Lloyd. Biochem. J., 1922, **16**, 530—540.

The influence of hydrochloric acid, sodium hydroxide, and sodium chloride on the gelling power of gelatin purified by dialysis at the isoelectric point has been followed. For comparative purposes, the minimum concentration of gelatin necessary to produce a gel after standing for 48 hrs. at 15° C. has been taken as an inverse measure of the gelling power. Under these conditions, pure gelatin requires a minimum concentration of 0·8% to form a gel. Hydrochloric acid decreases the gelling power, the diminution passing through a maximum at p_H 2—3 and again beyond p_H 0·7. Sodium hydroxide slightly decreases the gelling power between p_H 10—12 and completely prevents gelation above p_H 12. Neutral salts diminish the influence of hydrogen ions on gelling power; no other simple relationship between sodium chloride content and gelling power appears to exist. The influence of hydrochloric acid, sodium hydroxide, and sodium chloride on the production of turbid gels, and the effect of temperature on the optical rotation of gelatin have also been studied. The theory of gelation is discussed.—E. S.

Gelatin jellies; Elasticity of purified —— as a function of the hydrogen ion concentration. S. E. Sheppard, S. S. Sweet, and A. J. Benedict. J. Amer. Chem. Soc., 1922, 44, 1857—1866.

THE rigidity of demineralised gelatin jellies, which have been purified from the products of hydrolysis, is not much affected by changes of the hydrogen ion concentration except at very high ($>p_H$ 2) and very low ($<p_H$ 11) hydrogen ion concentrations. The addition of quantities of potassium-alum equivalent to 0·01—0·1% Al_2O_3 based on the dry gelatin brings about considerable changes in the rigidity-p_H curve, and markedly increases the rigidity. This may account for the somewhat anomalous effects observed when the rigidity of jellies prepared from commercial gelatins and containing different concentrations of acid and alkali was determined (*cf.* J., 1921, 313 A).—J. F. S.

PATENT.

Gelatin; Treatment of ossein for the production of ——. C. Collard. U.S.P. 1,431,217, 10.10.22. Appl., 23.8.21.

SEE E.P. 166,896 of 1921; J., 1922, 869 A.

XVI.—SOILS; FERTILISERS.

Sulphate reduction; Occurrence of —— in the deeper layers of the earth. C. A. H. van Wolzogen Kühr. Proc. K. Akad. Wetensch., 1922, 25, 188—198.

THE reduction of sulphate which occurs in the deeper clay strata and sand is brought about by *Microspira desulfuricans.* The life of this organism, which is adapted to anaerobic conditions, accounts for the common occurrence of sulphate reduction in the deeper layers of the earth and especially in the clay, which generally has a higher content of organic matter.—J. F. S.

Nitrogen-fixing bacillus; A new ——. G. Truffaut and N. Bezssonoff. Comptes rend., 1922, 175, 544—546.

THE bacillus, which is found in the soil, fixes nitrogen at the expense of various sugars. Measurements of the increase of nitrogen content of the nutritive medium show that the gain varies from 1·8 mg. per g. of dextrose consumed to 4·7 mg. in the case of lactose, when the carbohydrate concentration is 10 g. per litre this ratio is considerably increased with lower concentrations of the carbohydrate. Ethyl alcohol and acetic acid are also formed and, in addition, the bacillus reduces nitrates to ammonia derivatives. In appearance the organism somewhat resembles *Proteus vulgaris* but may readily be distinguished by characteristics which the authors describe. The name proposed is *Bacillus Truffauti.*—H. J. E.

Manganese content and proportion of ash in old and young leaves; Relation between ——. F. Jadin and A. Astruc. Bull. Soc. Chim., 1922, 31, 917—921.

WHEN the quantity of manganese present in leaves is considered with reference to the fresh material, young leaves contain less manganese than old, and the same result is obtained if the dry material is considered, but in this case the variation is not so great. When manganese content is compared with weight of ash, however, the ash from young leaves yields the higher percentage.—H. J. E.

Plant growth; Effect of the reaction of a nutritive solution on germination and the first stages of ——. R. M. Hixon. Med. K. Vetenskapsakad. Nobelinst., 1922, 4, [9], 1—28.

THE germination of seeds and growth of young plants as water cultures are considerably influenced by the hydrogen ion concentration of the nutritive solution. Experiments were made in which seeds were germinated in Tollens' solution, the p_H value of which was modified by addition of hydrochloric acid or sodium hydroxide, in tap water, and in sterilised agar with similarly adjusted p_H values. Germination took place over the wide range of p_H 4 to 7·6 with only slight variation at the two extremes, but in the middle part of the range there was a point where the rate of germination was a minimum. This point was at p_H 5 for two varieties of pea, p_H 6 for maize, wheat, and oats, and p_H 5·5 for carrots. On the other hand, the root growth of carrots was a maximum at this point on the tenth day. The critical point is probably the point of greatest efficiency and of normal growth. The greater rate of germination on either side of the critical point is probably due to the stimulating effect, in small concentration, of the toxic $H^{\cdot}$ and $OH^{\prime}$ ions. There is always a tendency for the p_H value, when this lies towards one or other extreme of the range in which a plant will grow, to become modified by the growing plant towards a value lying between p_H 5 and 6·8. When carrot plants 39 days old, grown in soil, were suspended in solutions of different p_H values, root excretions of a gelatinous nature (not protein) were observed, the quantity being greatest at extreme p_H values and least at the critical value p_H 5·5. These and other observations by different authors indicate an ionic equilibrium between the roots of the plant and the salts in solution.—E. H. R.

Fertilisers containing nitrites; Determination of total nitrogen in —— and of nitrite nitrogen in the presence of nitrates. F. Mach and F. Sindlinger. Z. angew. Chem., 1922, 35, 473—474.

Total nitrogen: 25 c.c. of an aqueous solution of the sample (the 25 c.c. should contain not more than 0·05 g. of nitrogen) is added slowly to a boiling mixture of 30 c.c. of saturated potassium permanganate solution and 5 c.c. of dilute sulphuric acid (1:2); after the addition of a further 10 c.c. of the sulphuric acid the mixture is cooled, treated with 10 g. of *ferrum reductum*, boiled gently for about 10 mins., and the resulting ammonia determined by distillation in the usual way. *Nitrate nitrogen:* 25 c.c. of the solution of the sample is boiled for 10 mins. with 30 c.c. of $N/3$ sulphuric acid and 10 c.c. of methyl alcohol. The nitrous acid is thus expelled in the form of its volatile methyl ester. After cooling, the mixture is neutralised and the residual nitrate determined as described by reduction with *ferrum reductum*. *Nitrite nitrogen:* The difference between the total nitrogen and the nitrate nitrogen gives the amount of nitrite nitrogen present. Allowance must be made for ammonia nitrogen if the fertiliser contains ammonium salts.—W. P. S.

Patents.

Phosphorus compounds; Process for treatment of —— suitable for manurial purposes. R. W. James. From Eisenwerkges. Maximilianshütte. E.P. 186,223, 9.8.21.

Insoluble phosphates, such as Florida phosphate, bone meal, or phosphatic slag, are intimately ground with salts of the alkalis, alkaline-earths, or magnesium, without heating. This treatment renders the phosphoric acid present soluble in citric acid and partly soluble in citrates. [Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 6429 of 1906 and 151,024; J., 1906, 647; 1920, 759 a.] —C. I.

Superphosphate masses; Process of and apparatus for ageing and disintegrating ——. A. Bruhn, Assr. to F. Krupp A.-G. U.S.P. 1,430,621, 3.10.22. Appl., 19.11.20.

See E.P. 147,134 of 1920; J., 1921, 863 a.

XVII.—SUGARS; STARCHES; GUMS.

White sugar manufacture; Process of —— employed at the Oxnard beet sugar factory, California. A. Vasseux. Bull. Assoc. Chim. Sucr., 1921, 38, 409—435.

In spite of the purity of the juice being as low as 80°, an extraction of 97% of the sugar present in the beets is realised at the Oxnard factory, the procedure being as follows: Diffusion juice is limed with the calcium saccharate from the Steffen process of desaccharifying molasses, using 5·25% CaO (calculated on the roots), carbonated to 0·93, heated to 92° C., filtered twice, treated with sodium carbonate, carbonated (without further addition of lime) to 0·26, heated to boiling, and the alkalinity lowered by sulphitation to 0·16 before passing to the multiple-effect supply tanks. The evaporator syrup (to which the second sugar has been added) is heated, sulphited to an alkalinity of 0·23, mixed with kieselguhr, and pumped successively through filter-presses and Danek filters, thus giving a "first liquor," which is very light in colour and low in viscous substances. This liquor serves for the boiling of the first crop of crystals, a small amount of white sugar grain of uniform size being added just at the moment when the grain is about to form, which addition not only facilitates boiling, but obviates the formation of false grain, gives a sugar of better colour, and improves the extraction (*cf.* J., 1919, 48 a). The molasses from the first sugar is sulphited, treated with kieselguhr, and filtered before being boiled for the production of the second sugar, the molasses from which is sent to the Steffen plant for the extraction of the sugar still remaining in it. In the 1919 season the total sugar in the roots was 18·71; that actually recovered was 18·21 (or 97·35%); that remaining in the pulp was 0·11; in the diffusion waste waters, 0·03; in the scums, 0·08, and in the Steffen waste waters, 0·17%. Altogether about 40,000 tons of white granulated sugar was produced at the Oxnard factory during 1920.—J. P. O.

Cane juice; Influence of the non-sugars of —— in inhibiting inversion. C. Lourens. Archief Suikerind. Nederl.-Indië, 1922, **30**, 562—564. Int. Sugar J., 1922, **24**, 552.

The author agrees with van Ligten (J., 1922, 776 a) that amino-acids are capable of exerting an influence in retarding the inversion of sugar solutions, but suggests that a more likely explanation of the slow rate of inversion observed when sulphiting cane factory syrups and molasses (as compared with pure solutions of the same density treated under the same conditions) is that salts forming part of the non-sugars are decomposed, the sulphur dioxide combining with the alkalis and liberating organic acids. These organic acids have an inversion constant which is only about 0·5, as compared with one of 40 for sulphur dioxide.—J. P. O.

[*Sugar factories;*] *Significance of the presence of oxalates in evaporator incrustations* [*in* ——]. [*Detection of oxalic acid.*] C. Müller. Int. Sugar J., 1922, 24, 523—524.

Analyses of the incrustations scraped from the heating surfaces of a quadruple effect evaporator used for the concentration of cane juice showed, when operation was normal, the presence of a comparatively considerable amount of oxalic acid in that taken from the first vessel, traces only in that from the second, and none in that from the third and fourth. On the other hand, in the case of a similar apparatus, the operation of which was less efficient (the second vessel hardly operating at all), the presence of much oxalic acid was established in the incrustation taken from both the first and the second vessels, while there was also a trace in that from the third. The presence of oxalic acid in the second or subsequent vessels of the evaporator may be taken as an indication of the irregular operation of the apparatus, the concentration of the syrup in these vessels being insufficient to cause the complete precipitation of the calcium oxalate in the juice, this substance being almost insoluble in concentrated syrup. In testing for the presence of oxalic acid, 100 g. of the incrustation (freed from traces of sugar by repeated washing with water) is treated with 300 c.c. of dilute sulphuric acid (1:10), and the liquid filtered and evaporated to about 50 c.c.; then 10 c.c. is further concentrated in a test-tube, a little resorcinol added, and 2 c.c. of concentrated sulphuric acid poured down the side of the tube. On agitation, a fine azure blue colour turning violet on heating is formed. Tests with fourteen other organic acids showed that the reaction is characteristic of oxalic acid.—J. P. O.

Decolorising carbon [*for use in the sugar industry*]; *Essential qualities of an efficient ——.* W. H. Dunstone, jun. Facts about Sugar, 1922, 14, 416.

An efficient decolorising carbon after having been used for the adsorption of impurities from sugar liquors must be capable of readily being separated by filtration. The optimum size of particle depends on the porosity and adsorbing quality of the carbon. Frequently extremely fine carbon becomes so "slimed" by the accumulation of organic colloidal impurities that it cannot be filtered off. Another important quality is a sufficiently hard structure, otherwise the attrition occurring in revivifying results in the formation of such a quantity of very fine grain as seriously to impede filtration. —J. P. O.

Decolorising carbons; Experiments with various ——. E. Saillard. Suppl. Circ. Syndic. Sucre de France, Nos. 1724, 1726, 1728, 1730, and 1734 of 1922.

To 50-c.c. portions of a 20% solution of beet molasses, 0·5 g. of decolorising carbon, or 0·5 g. of finely ground animal charcoal, was added, the temperature being maintained at 78°—80° C. during 20 mins. After cooling, and filtering, the colour removed, expressed as percentage of original colour, was found to be as follows: Animal charcoal, 27;

"Norit," 43; "Darco," 44; and "Carboraffin," 75. Practically the same results were obtained when the treatment was carried out at the ordinary temperature. Other experiments led to the following conclusions: A better decolorisation results when the treatment is effected under pressure at 110° C. than at 78°—80° C.; the finer the state of division of the carbon the better its action in adsorbing colour; animal charcoal adsorbs about twice the amount of calcium salts from solution in comparison with "Carboraffin," and three times that retained by "Darco." On the other hand, animal charcoal takes up less free alkali than "Darco."—J. P. O.

Decolorising carbon ("Norit"); Technical application of ——. W. H. Dunstone, jun. La. Planter, 1922, 68, 254—256.

Washed white sugar of 99° purity was melted to a syrup of 56° Brix, strained, heated to 200° F. (93° C.), and discharged into mixing tanks in which a determined amount of "Norit" (about 1·5% of the weight of melted sugar) had been placed in the form of a paste. After filtration through plate-and-frame presses, a practically colourless liquor was obtained from which a "standard granulated, the equal in every way of the best boneblack sugar," could be boiled. After being used in this manner three times in succession, the "Norit" was washed with water in filter-presses to eliminate its sugar content, dried, and heated in the "Norit" kiln to about 1100° F. (660° C.), after which it was used again three times. When the ash content of the carbon had reached such a degree as to hinder filtration, it was reduced by boiling with a 2% solution of hydrochloric acid, this treatment at intervals being followed by boiling with a 5% solution of sodium hydroxide. It is stated that a recovery of 93 lb. of standard granulated sugar per 100 lb. of 96° raw sugar can be obtained, and that the process can be conducted on a commercially profitable scale.—J. P. O.

Decolorising carbon ("Norit"); Cost of revivification of ——. R. G. Tillery. La. Planter, 1921, 66, 411—414; 1921, 67, 9—14.

Revivification by acid treatment was found to cost 0·8 cent per lb. of decolorising carbon; by caustic alkali treatment, 1·75 cent; and by re-burning, 0·61 cent. Not only is re-burning cheaper (its cost amounting to $0·01 per 100 lb. of granulated sugar produced), but it gives a material which decolorises better, and filters faster, the loss during the process of revivification also being less. Re-burning, however, should be combined with an occasional acid and alkali treatment.—J. P. O.

Sugars; Chemistry of the ——. H. Kiliani. Ber., 1922, 55, 2817—2826. (*Cf.* J., 1921, 315 A; 1922, 188 A.)

The technique of the oxidation of sugars and polyhydroxy acids by nitric acid at the atmospheric temperature is further improved by removing any excess of nitric acid by shaking the solution, after dilution if necessary, with five or six portions of ether (each one and a-half times the volume of the solution). The sixth extract is generally free from nitric acid. The aqueous solution may still contain nitric esters. It is allowed to remain exposed to the air for 12—24 hrs. to permit the dissolved ether to evaporate and is then concentrated if necessary in a vacuum over sulphuric acid. During this period the nitric esters become hydrolysed gradually and the liberated nitric acid causes a fresh oxidation. For reasons of safety, the ethereal extracts are immediately brought into contact with sodium hydroxide solution (1 in 3). The efficiency of the process is illustrated by the identification of *l*-trihydroxyglutaric acid as a by-product of the preparation of ketorhamnonlactone and by the preparation of *r*-pentahydroxypimelic acid from α-glucoheptoni acid. The strongly reducing acid obtained by th oxidation of dextrose or *d*-gluconic acid with nitri acid is identified as 5-keto-*d*-gluconic acid. Th ketorhamnonic acid described previously as th 2-keto- is shown to be the 5-keto-compound. (C J.C.S., Dec.)—H. W.

Carbohydrates. II. A new anhydride (1.2) *of dextrose.* P. Brigl. Z. physiol. Chem., 1922, 122, 245—262.

By the elimination of hydrogen chloride from 1-chloro-3.5.6-triacetylglucose, the 1.2 anhydride has been prepared and its properties examined. 1-Chloro-3.5.6-triacetylglucose is treated in benzene solution with ammonia whereby 3.5.6-triacetylglucose-1.2-anhydride, white prisms m.p. 59·5° C., $[\alpha]^{18}_{D}+106·5°$, is obtained. This substance reacts with great ease with acetic anhydride, water, or methyl alcohol. (*Cf.* J.C.S., Nov.)—W. O. K.

Polysaccharides. XVI. P. Karrer and W. Fioroni. Ber., 1922, 55, 2854—2863.

Re-determination of the heats of combustion of the amyloses gives results which indicate that polymerisation proceeds exothermally from diamylose to α-tetra-amylose and then strongly endothermally to octa-amylose. The observed values for the heats of combustion of a sugar of the general formula, $(C_6H_{12}O_6)_n-(n-1)H_2O$, agree excellently with the calculated values. The heats of combustion of a number of polysaccharides and their derivatives are given. The close agreement between the observed values for the acetyl compounds of cellulose, starch, and inulin, and those calculated on the hypothesis that the heat of acetylation (known to be small) is relatively negligible indicates that acetylation is not accompanied by depolymerisation, since in the case of the amyloses it has been shown that the heat of combustion varies considerably with the degree of polymerisation. In reply to the recent criticism of Pringsheim (J., 1922, 513 A) the author maintains that triamylose and β-hexa-amylose are identical.—H. W.

Reduction of carbohydrates. Willstätter and others. *See* V.

Patents.

Sugar and other products; Method of converting wood into ——. S. F. Acree. E.P. 160,776, 18.3.21. Conv., 25.3.20.

Cellulosic material containing galactan, such as Western larch, is subjected to hydrolysis, a hydrolysing agent, such as nitric acid, nitrous acid, or a mixture of both, or sulphurous acid, or various acidic liquors recovered in subsequent manipulations, being used. The quantity of hydrolytic agent is preferably less than 6% of the dry weight of the raw material employed. The wood, preferably as chips or sawdust, is mixed with three times its weight of water, the acid added, and the whole heated either at ordinary pressure to 70°—100° C., or under increased pressure to 110°—140° C., until hydrolysis is complete. The resulting sugar solution is removed and may be treated for the separation of galactose and other sugars as such, or may be fermented by means of special yeasts to give alcohol. The process is rendered continuous by the use of batteries of hydrolysing and extraction vessels.—W. H. G.

Glucose and dextrin; Process of, and apparatus for obtaining —— from wood. H. Terrisse and M. Levy. E.P. 186,139, 20.6.21. Addn. to 143,212.

The process described in the former patent (J., 1921, 405 A) has been simplified to allow of continuous working. Cellulosic material, such as wood shavings, sawdust, etc. is dried to a moisture content of not more than 5%. Ten parts of the dried material is mixed with about 7—11 pts. of 40% hydrochloric acid and simultaneously treated with about 2 pts. by weight of gaseous hydrogen chloride, the temperature being kept low throughout. The mass is then digested in thin layers at 12°—50° C. under slight pressure. When conversion is complete the hydrochloric acid is removed and recovered and the product boiled with water to convert dextrin into glucose, which may e separated as such or fermented. Apparatus, onsisting of a mixing vessel, a digesting installaon, and a plant for the recovery of the acid, ranged to allow of the continuous working of the rocess, is described.—W. H. G.

ugar solutions; Purification of —— by filtration and decantation. F. Tiemann. G.P. 355,231, 17.12.20. Addn. to 354,076 (*cf.* E.P. 161,987; J., 1921, 633 A).

N the process described in the chief patent, the ose, granular filter medium is supported on a ieve constructed of elastic material, and by setting he sieve in motion, fine sand is readily separated rom coarser particles and can be washed away. —L. A. C.

XVIII.—FERMENTATION INDUSTRIES.

Malt analysis; Standard methods of ——. Report of Standing Committee on Analysis. J. Inst. Brewing, 1922, 28, 775—786.

HE revised methods of analysis of malts and aramel differ in details from those recommended n the reports of 1906 and 1910 (*cf.* J., 1906, 236; 910, 1323). The methods being entirely empirical, niform results can be obtained only by strict bservance of the details laid down. In addition o the Seck laboratory mill, a mill made by Messrs. R. Boby, Ltd., of Bury St. Edmund's, is now ccepted as standard, and for grinding the grist a oller setting of 0·5 mm.—as determined by a feeler gauge—is prescribed. In determining the extract of pale malts, the mash is kept at 150° F. (65·5° C.) for 1 hr., the practice of heating to 158° F. (70° C.) for the last 5 mins. being abandoned. The conditions of filtration of the worts are standardised; the first 50 c.c. is to be returned to the funnel and 250 c.c. finally collected. For reading the tint of worts any recognised "daylight" lamp may be used. Covered dishes are prescribed for moisture determinations, and various precautions to be observed are enumerated. The "tube" method of estimating diastatic activity has been re-introduced as an official method, in addition to that previously given; and more exact details for the preparation of soluble starch are laid down. No alterations have been made in the methods of analysis of coloured malts and caramel. —W. H. G.

Hop bitters; Nomenclature and analysis of ——. P. Kolbach. Woch. Brau., 1922, 39, 233—235.

The lack of uniformity in the nomenclature of hop constituents is emphasised and the question of the possibility of valuing hops on the basis of a chemical analysis is discussed.—W. H. G.

Physico-chemical methods in brewery laboratories. W. Dietrich. Woch. Brau., 1922, 39, 232—233.

The limitations of purely chemical methods are pointed out, and stress is laid on the value of the information given by modern methods of physical chemistry. The determination of p_H values, nephelometric experiments, determination of viscosity and surface tension and studies of colloidal state, ultrafiltration, and the use of the ultramicroscope and microchemical methods are instanced as examples of physical methods of value for supplementing chemical methods of examination. —W. H. G.

Colour in beers and worts; Standard solution for the estimation of ——. B. Lampe. Woch. Brau., 1922, 39, 235—236.

A mixture of solutions of cobalt nitrate and potassium bichromate is suggested as a standard. It has the advantage over the standards now in use —ferric alum, iodine, and aniline dye solutions— that it is stable for a considerable period and that the salts required can be obtained readily in a pure condition.—W. H. G.

Saccharase [invertase]; Inactivation of —— by iodine. H. von Euler and S. Landergren. Biochem. Zeits., 1922, 131, 386—389.

Addition of iodine in potassium iodide to two invertase preparations of different activity reduced the activity in each case to one half. Sodium thiosulphate cannot re-activate the invertase.—H. K.

Saccharase [invertase]; A silver compound of ——. H. von Euler and K. Josephson. Ber., 1922, 55, 2416—2420.

A brown compound of silver and invertase is precipitated by the addition of alcohol to a solution of invertase (1%) which has been treated with silver nitrate. The compound still contains approximately 50% of carbohydrates which are derived mainly from the original yeast. The atomic ratio of phosphorus to silver in the compound is 1:1. (*Cf.* J.C.S., Nov.)—H. W.

Lactic acid fermentation of dextrose by peptone. G. Schlatter. Biochem. Zeits., 1922, 131, 362—381.

Dextrose is converted quantitatively into inactive lactic acid by peptone at 37° C., sodium bicarbonate being used as buffer. This buffer substance may be replaced by sodium acetate, but not by phosphate mixtures owing to flocculation of the peptone. During the fermentation amino-acids appear and fermentation ceases with flocculation of the peptone. Peptones free from phosphates, as, for example, Witte peptone, give no fermentation; most of the observations recorded were made with Siegfried's peptone. The solutions were not completely sterile, although no known bacteria capable of forming lactic acid were found.—H. K.

Peptone fermentation. E. Baur and E. Herzfeld. Biochem. Zeits., 1922, 131, 382—385.

The authors draw an analogy between the glycolytic action of plant and animal juices and the fermentation of dextrose by peptone as revealed by their own experiments and those of Schlatter (*cf. supra*). The latter are moreover an effective reply to Bau's criticism (J., 1922, 189 A) of their own experiments on fermentation without yeast (J., 1921, 900 A). —H. K.

Wines containing sulphurous acid; Determination of the volatile acidity of ——. R. Marcille. Ann. Falsif., 1922, 15, 269—274.

When an aqueous solution of sulphurous acid is treated with iodine, the increase in the acidity is a measure of the quantity of sulphurous acid present: $SO_2+2H_2O+2I=H_2SO_4+2HI$. In the case of wines containing sulphurous acid, combination of the latter with aldehydic substances takes place and the sulphurous acid thus combined is not oxidised by iodine; its acidity is also reduced. Based on these facts, the following method of correcting the volatile acidity of wines in order to ascertain the quantity of volatile organic acids is suggested. From the total volatile acidity is deducted a quantity equal to the sum of the amount of the sulphurous acid oxidisable by iodine *plus* 70% of the combined sulphurous acid. The combined sulphurous acid is the difference between the total sulphurous acid and that portion which is oxidisable by iodine.—W. P. S.

Citric acid; Detection of —— in wine and musts. C. von der Heide and H. Straube. Festschr. Jubiläum höheren staatl. Lehranst. Wein-, Obst-, u. Gartenbau, 336—369. Chem. Zentr., 1922, **93**, IV., 803.

Methods depending on the separation of citric acid in the form of its salts are unreliable on account of possible contamination with malic acid. Stahre's reaction (J., 1896, 53) or the modifications of it proposed by Kunz (J., 1915, 974; 1919, 435 A), and Krug and Rettinger (Arbb. Kais. Gesundh.-Amt, **49**, 28), are recommended. The authors precipitate the barium salts of the acids in wines and musts by means of alcohol, and examine the precipitate for citric acid. Contrary to Kunz' assumption, it has been shown that natural wines and musts may contain citric acid. In nine Rhenish natural wines of the 1921 vintage, citric acid was found in quantities of 85—164 mg. per l. Whether citric acid is a normal constituent of German wines is uncertain.
—W. H. G.

Rum; Testing —— by the odour developed on treatment with sulphuric acid. E. Schäffer. Chem.-Zeit., 1922, **46**, 934.

If 10 pts. of rum is mixed with 4 pts. of sulphuric acid (sp. gr. 1·84) an aroma is at first developed which differs with different samples, but when this has disappeared it is followed by a characteristic odour somewhat resembling that of petroleum. The same odour was obtained with 15 different samples of genuine rum from Jamaica, Cuba, Martinique, and Guadeloupe, even when adulterated to the extent of 1 part in 10. The odour lasted at least 24 hrs. The so-called German rum (*cf.* J., 1922, 73 A) and an artificial rum prepared from essences did not give this characteristic odour. The test would therefore be useful for distinguishing these. Genuine rum containing a large amount of ethyl acetate only gives the characteristic odour after removal of the ethyl acetate by distillation.

Nitrogen-fixing bacillus. Truffaut and Bezssonoff. *See* XVI.

PATENTS.

Brewing of malt liquors. C. F. Hyde. E.P. 186,161, 22.6.21.

In nearly all malt samples the growth is somewhat uneven and there is in consequence a proportion of unmodified or poorly modified corns. These "riceyended" corns in the usual mashing operation yield little or no extract and are thus waste. A modified process consists in separating the unmodified grits from the remainder of the grist by mechanical means, and treating these separately by suitable methods to render this unaltered starch soluble, or, by a further crushing, to expose a greater surface to the action of the malt enzymes. The whole or nearly the whole of the available extract is thus obtained. In one modification the solution obtained by converting the grits is diluted and used as mashing liquor. [Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 13,838 of 1906; J., 1907, 162.]—W. H. G.

Beverage-making material and process of producing the same. G. K. Mayer, W. C. Andrews, and A. V. Colby. U.S.P. 1,391,557, 20.9.21. Appl., 14.7.20.

Malt, corn (maize) or other cereal is moistened and heated to 120° F. (49° C.) in a steam-heated cylinder, then stored for ¼ hr., and treated with live steam for 1—5 mins. in a cylinder, which it leaves at a temperature of 200° F. (93° C.). The material is then cooled, crushed between flaking rolls, passed through a jacketed heater wherein it is heated to 140° F. (60° C.), cooled, and then passed through several dryers of progressively rising temperature, the final temperature being 190° F. (88° C.). By suitably regulating the time and temperature it is possible to obtain products giving beverages of any desired low alcohol content (down to zero) on subsequent brewing by the usual lager beer process.

XIXA.—FOODS.

Meats; Pickling —— in solutions containing potassium nitrate and sodium nitrite. L. Pollak. Z. angew. Chem., 1922, **35**, 392. (*Cf.* J., 1922, 606 A.)

A reply to Auerbach and Reiss (*loc. cit.*); the differences between the results found by these observers and those obtained by the author appear to be due to differences in the pickling operations.—W. P. S.

Butter; Acetic index [improved Valenta test] in detecting adulteration of ——. G. Fascetti. Giorn. Chim. Ind. Appl., 1922, **4**, 352—355.

Butter, margarine, and coconut butter are readily differentiated by means of the acetic index, determined as follows. Through the stopper of a stout test-tube 18 cm. long and 1·8 cm. bore, a thermometer, 8 mm. in diameter, reaches to 0·5 cm. from the bottom of the tube. The test-tube is fitted, by means of a rubber ring, in a second tube of the same length and 3 cm. in diameter, this being filled to the extent of one-half either with water or, for temperatures above 100° C., with glycerin. A large beaker standing on an asbestos gauze and half filled with water or glycerin, serves as the heating bath. The butter or fat is melted in a small beaker and filtered through a dry filter, the oily layer being then accurately decanted from the lower milky layer. Exactly 1 c.c. of the fat is then introduced from a slightly heated pipette on to the bottom of the small test-tube, this being followed by exactly 4 c.c. of pure acetic acid (as sold for molecular weight estimations) which has been diluted to the specific gravity 1·062, corresponding with 98·5% of acetic acid. The thermometer is fixed in position and the tube fitted to the larger one, the whole being swung gently to and fro in the heated bath until the turbid mixture becomes clear. The tubes are then withdrawn from the bath and the agitation continued until the solution turns cloudy, the temperature (t° C.) being then read. If the butter is not quite fresh or exhibits a rancid taste, 2 g. of the fat, separated as above, is dissolved in a mixture of ether and alcohol and the solution titrated with $N/20$ aqueous alcoholic sodium hydroxide solution in presence of phenolphthalein. The number of c.c. of the alkali solution required is added to the temperature *t* to obtain the "acetic index" of the fat. For fresh butter this was found to have the value 64—68, for rancid butter 63·4—65, for coconut fat 29—34, and for margarine 113·5—118. Addition to fresh butter of 5% of coconut fat lowers the index by 3—4, whilst the same proportion of margarine raises it by 4—5. In the rare cases in which butter is adulterated with both coconut fat and margarine, the test loses its value.—T. H. P.

Margarine; Water-content of ——. A. Gronover and F. Bolm. Chem.-Zeit., 1922, **46**, 933—934.

Tests with samples taken out of a margarine mixing machine and from packages containing from 30 to 130 lb. showed that the margarine was in all cases perfectly homogeneous as regards water content throughout the mass. It is therefore considered reasonable to expect manufacturers to guarantee each package of margarine to contain less water than the percentage allowed by law. In the case of pound packets the outer layers lose some water by evaporation, but in the cases examined the outer layers did not show more than about 1% less water than the centre of the packets.—H. C. R.

Vitamin A; Synthesis of —— by a marine diatom (Nitzschia closterium, W. Sm.) growing in pure culture. H. L. Jameson, J. C. Drummond, and K. H. Coward. Biochem. J., 1922, **16**, 482—485.

The marine diatom, *Nitzschia closterium*, is able to synthesise large amounts of vitamin A when grown in Miquel's solution or in sterilised sea water.
—E. S.

Vitamin A; Origin of the —— in fish oils and fish liver oils. J. C. Drummond, S. S. Zilva, and K. H. Coward. Biochem. J., 1922, **16**, 518—522.

The vitamin A contained in the liver oils from the cod and other fishes is probably derived through the smaller fishes and the plankton from marine algæ, which have been shown to be capable of synthesising this vitamin (*cf. supra*).—E. S.

Lemon-juice; Growth-promoting factor [vitamin] of ——. B. Leichtentritt and M. Zielaskowski. Biochem. Zeits., 1922, **131**, 499—512.

The growth-promoting factor of lemon-juice has been submitted to a variety of conditions. Lemon-juice heated to 100° C., either in acid or alkaline solution, is practically unaltered in its growth-promoting factor for bacteria. Even hydrolysis with 2—3% hydrochloric acid is without influence, although sodium hydroxide is inimical. Exposure to ultraviolet light or Röntgen rays is without action whatever the reaction of the media, and aeration in boiling solution is also without action. Adsorbents weaken the activity, and the bacterial growth-promoting principle is dialysable, independently of the reaction of the medium.—H. K.

Lemon-juice; Growth-promoting factor of ——. B. Leichtentritt and M. Zielaskowski. Biochem. Zeits., 1922, **121**, 513—524.

There is little parallelism between the effect of external conditions and reagents on the bacterial growth-promoting factor and the anti-scorbutic factor C of lemon-juice as tested on guinea pigs and children. Lemon-juice contains an anti-scorbutic factor C and a factor which promotes growth of bacteria. This latter factor is termed vitamin D. Further experiments are necessary to determine whether D is not identical with vitamin B.—H. K.

Pepper substances. Ott and others. *See* XX.

Patents.

Food product obtained from brewers' yeast. J. C. Miller, Assr. to The Evaporating and Drying Machinery Co. U.S.P. 1,391,561—2, 20.9.21. Appl., 19.3.18.

Waste brewers' yeast is supplied to a rapidly rotating cylinder from the end of which it is discharged by centrifugal force as an annulus of fine spray, in which form it is rapidly dried by means of a current of heated air blown across it. (a) If the air be heated to 155° F. (68° C.) or above, the peptones present in the protoplasm of the yeast cells are liberated and the product, in the form of a dry flour, is suitable as a partial or complete substitute for wheat flour for human consumption. (b) If the temperature of the air be kept at 110°—120° F. (43°—49° C.), the yeast cells are not disintegrated, and the product is practically free from peptones, contains the active ferments of the yeast present as in the original material, and forms a valuable force feed for animals.

Yeast food; Production of ——. A. H. Gallagher, Assr. to National Retarder Co. U.S.P. 1,431,448, 10.10.22. Appl., 15.5.20.

The protein of chrome-tanned leather is hydrolysed by treatment with lime at a high temperature. The product contains amino-acids and proteoses, and is suitable for use as a yeast nutrient in growing bakers' yeast, yielding a yeast of good colour, odour, and keeping qualities, and which has good baking strength in the manufacture of leavened bread.
—L. A. C.

Bread; Manufacture of leavened ——. C. Hoffman, H. D. Grigsby, and N. M. Cregor, Assrs. to Ward Baking Co. U.S.P. 1,431,525, 10.10.22. Appl., 1.10.21.

A bread loaf equal in colour and texture to that made from highly milled bolted flour contains added water-soluble B vitamin and soluble nitrogen compounds extracted from vegetable material, in addition to the usual constituents.—L. A. C.

Yeast; Composition of matter for increasing growth of —— when mixed with dough. W. A. and E. W. Geere. U.S.P. 1,431,156, 10.10.22. Appl., 23.2.21.

See E.P. 143,938 of 1917; J., 1920, 556 A.

Fish and the like; Cooling and freezing of ——. J. J. Piqué. U.S.P. 1,431,328, 10.10.22. Appl., 21.5.20.

See E.P. 154,250 of 1919; J., 1921, 94 A.

XIXb.—WATER PURIFICATION; SANITATION.

Water supplies; Chlorine treatment of ——. Vollmar. Gas und Wasserfach, 1922, **65**, 649—654.

For the disinfection of town water supplies the author recommends the preparation of a concentrated chlorine solution which is allowed to flow into the water main at a point just before the pump intake. The amount of chlorine which flows into the mixing chamber is determined by means of a differential manometer, and can be accurately controlled in conformity with the character of the water under treatment. The amount required per litre of Elbe water at Dresden varied from about 0·16 to 0·34 mg., with which quantity the bacterial content of the water was reduced from several thousand to an average of 4—20 per c.c., consisting mostly of harmless spore-forming bacteria. The quantity of chlorine was daily so adjusted that directly behind the pumps chlorine could not be detected chemically in the water. At this point it was usually perceptible to the taste, but at the outflow of the reservoir the water had no undesirable taste whatever. The addition of a sufficiently effective quantity of chlorine was assured by bacteriological control.—G. F. M.

X-rays; Action of secondary radiation of —— on microbes. J. Cluzet, A. Rochaix, and T. Kofman. Comptes rend., 1922, 175, 546—548.

Numerous experiments showed that neither hard nor soft X-rays destroy bacteria or even retard their growth, but when cultures are exposed to the secondary radiation development ceases. The latter result was obtained by using radiators of heavy metals of low atomic weight, but very penetrating primary radiation apparently excites the radiating material unsuitably, so that bacteria remain unaffected.—H. J. E.

Patent.

Soap or compound; Antiseptic and insecticidal ——. R. Macpherson and W. E. Heys. E.P. 186,078, 15.3. and 30.9.21.

The compound comprises a mixture of sodium or potassium soap, an alkali benzoate, and tar. Birch tar is preferred, but any other vegetable or mineral tar may be used. The ingredients may be thoroughly incorporated by mixing, or the compound produced by saponifying a mixture of fatty acids, benzoic acid, and tar.—H. C. R.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Paniculatine, the alkaloid of Aconitum paniculatum, Lam. G. E. Brunner. Schweiz. Apoth.-Zeit., 1922, **60**, 357—358. Chem. Zentr., 1922, **93**, III., 1007.

The alkaloid isolated from the tubers of the paniculated aconite is not identical with aconitine. It has the molecular formula, $C_{29}H_{35}O_7N$, and crystallises from methyl alcohol in small rhombic prisms, m.p. 263° C.—G. F. M.

Digitalis leaves; Extraction of the active principles from ——. E. Mameli. Giorn. Chim. Ind. Appl., 1922, **4**, 355—358.

Prolonged extraction of dried digitalis leaves with absolute alcohol in a Soxhlet apparatus, followed by concentration and purification of the united extracts and separation of the different active principles by means of various solvents, yields a total quantity of these principles greater than is obtained when the water and alcohol are used under other conditions. Details of the method of extraction and separation are given.—T. H. P.

Ergot. A. Stoll. Schweiz. Apoth.-Zeit., 1922, **60**, 341—346, 358—364, 374—383. Chem. Zentr., 1922, **93**, III., 1007.

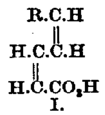
The improbable assumption that simple amines of the tyramine type are the active principles of ergot is refuted by the fact that even by the most careful manipulation only the merest traces of such substances can be isolated from the fungus. A hitherto unknown amine of high molecular weight having the characteristic therapeutic action of ergot was however isolated from the drug. After the addition of acid reagents, such as aluminium sulphate, to the powdered ergot, about 350—400 g. of ergot oil free from alkaloid was obtained from 1 kg. of material by exhaustive extraction with ether and benzene. From the acidified cell material a crystalline alkaloid, ergotamine, $C_{33}H_{35}O_5N_5$, crystallising from acetone with 2 mols. $(CH_3)_2CO$ and 2 mols. of water, was obtained in a yield of 0·1—2·0 g. per kg. of ergot. The crystals effloresce when exposed to the air and soon decomposition sets in accompanied by discoloration. On standing, or more rapidly on boiling a methyl alcoholic solution, ergotamine is converted into an isomeride of feebly basic properties, termed ergotaminine, which crystallises in leaflets from the solution. Both ergotamine and ergotaminine give in acetic acid solution in presence of ethyl acetate a blue coloration with sulphuric acid. Therapeutically ergotamine exhibits the typical action of ergot up to dilutions of 1 in 10 million. Ergotamine is a very unstable mon-acid base, having $[\alpha]_D^{20} = -155°$ in 0·6% chloroform solution. Ergotaminine under similar conditions has $[\alpha]_D^{20} = +381°$.—G. F. M.

Artemisia Afra, Jacq.; Constituents of the flowering tops of ——. J. A. Goodson. Biochem. J., 1922, **16**, 489—493.

The following substances have been isolated: camphor, a wax-like ester, probably ceryl cerotate, tricontane, scopoletin, and quebrachitol. The camphor had $[\alpha]_D^{20} = +9·7°$ and was evidently a mixture of the two enantiomorphs. No compounds were found which could be regarded as related to santonin.—E. S.

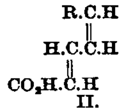
Pepper substances; Natural and artificial —— II. Chavicine from pepper-resin, the primarily active constituent of black pepper. E. Ott, F. Eichler, O. Lädemann, and H. Heimann. Ber., 1922, 55, 2653—2663.

The isolation of pepper-resin from *Piper nigrum*, Singapore, is described in detail, the product ultimately consisting of chavicine containing appreciable quantities of wax. The former is shown to be a piperidide of chavicinic acid, I.,



$$\begin{array}{c} R.C.H \\ \| \\ H.C.C.H \\ \| \\ H.C.CO_2H \end{array}$$

I.



$$\begin{array}{c} R.C.H \\ \| \\ H.C.C.H \\ \| \\ CO_2H.C.H \end{array}$$

II.

it is very resistant to hydrolysis by alcoholic sodium hydroxide solution and its acid constituent becomes isomerised during the process to isochavicinic acid, II., a yellow amorphous solid, m.p. 200°—202° C., which resembles piperic acid very closely. It is catalytically hydrogenated in alcoholic solution in the presence of palladinised animal charcoal to tetrahydropiperic acid. (*Cf.* J.C.S., Nov.)—H. W.

Betulin. H. Schulze and K. Pieroh. Ber., 1922, 55, 2332—2346.

Betulin, isolated from birch bark, crystallises from alcohol with 1 or 0·5 molecule of solvent which has been overlooked by previous investigators. It has the composition, $C_{31}H_{52}O_2$ or $C_{32}H_{54}O_2$, as established by the analyses of the compound itself, its hydrogen phthalate and succinate, and its diacetate. It is converted by boiling formic acid (90%) into an isomeric substance, allobetulin, which contains one hydroxy group, the other oxygen atom being contained in an ether-like group. Allobetulin and its derivatives have higher melting points and are less soluble than betulin and its compounds and are more stable towards chemical reagents. Apparently betulin and allobetulin belong to the dextrorotatory phytosterols. (*Cf.* J.C.S., Nov.)
—H. W.

Aromatic arsenious acids; Synthesis of ——. H Bart. Annalen, 1922, **429**, 55—103.

Details are given for the preparation of the following arsenious acids by the interaction of a diazonium solution with acid or alkaline arsenit solution:—phenylarsenious acid, *o*-, *m*-, and tolylarsenious acids, *p*-ethoxyphenylarsenious aci p-acetylaminophenylarsenious acid, o-, m-, and p-chlorophenylarsenious acids, o-, m-, and p-carboxyphenylarsenious acids, p-phenylenediarsenious acid, o- and p-hydroxyphenylarsenious acids, o-, m-, and p-nitrophenylarsenious acids, op-dinitrophenylarsenious acid, 5-nitro-2-hydroxyphenylarsenious acid, o-nitro-p-hydroxyphenylarsenious acid, and m-nitro-p-hydroxyphenylarsenious acid. Diphenylhypoarsenious acid is obtained from benzenediazonium chloride and phenylarsine oxide, p-nitrophenylhypoarsenious acid by reduction of p-nitrophenylarsenious acid, and di-p-nitrophenylhypoarsenious acid by treatment of the preceding compound with diazotised p-nitroaniline.—C. K. I.

Aromatic arsenious acids; Synthesis of —— by the interaction of isodiazo-compounds with the arsenite ion. H. Bart. Annalen, 1922, **429**, 103—113.

The same end product is obtained if in the general reaction referred to in the preceding abstract the diazonium solution is replaced by alkaline isodiazotates. Details are given for the preparation by this method of the following substances: o-, m-, and p-nitrophenylarsenious acids, phenylarsenious acid, o-carboxyphenylarsenious acid, and p-carboxyphenylarsenious acid.—C. K. I.

Salvarsan base (mml-diamino-pp'-dihydroxyarsenobenzene); Two new syntheses of ——. H. Bart. Annalen, 1922, **429**, 113—122.

The first synthesis consists in converting 3-amino-3-hydroxyazobenzene into 4-hydroxy-3-phenylazophenylarsenious acid, which on reduction yields the required substance. The second synthesis starts with p-nitro-o-aminophenol, which is condensed with chlorocarbonic ester, and the urethane so obtained reduced to give p-amino-o-carbethoxyaminophenol. This is readily converted into m-carbethoxyamino-p-hydroxyphenylarsenious acid, which on reduction gives the urethane of the required base.—C. K. I.

Gallaldehyde and its derivatives. K. W. Rosenmund and E. Pfannkuch. Ber., 1922, **55**, 2357—2372.

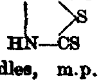
Reduction of gallaldehyde by hydrogen in the presence of spongy platinum or palladium gives an amorphous product of high molecular weight instead of gallyl alcohol. Gallaldoxime is reduced mainly to digallylamine $NH[CH_2.C_6H_2(OH)_3]_2$. Triacetylgallaldoxime acetate, on the other hand, gives triacetylgallylamine from which gallylamine is obtained by hydrolysis. Unexpectedly, the bases and their acetyl derivatives excite a powerful contractile action on the isolated uterus of the guinea-pig. (*Cf.* J.C.S., Nov.)—H. W.

Dulcin; Derivatives of ——. P. Herrmann. Annalen, 1922, **429**, 163—174.

The preparation of a number of derivatives and analogues of dulcin is described. None of them however possess sweetening properties. (*Cf.* J.C.S., Dec.)—C. K. I.

Diethylrhodanine. C. S. Leonard. Med. K. Vetenskapsakad. Nobelinst., 1922, **4**, [14], 1—13.

Diethylrhodanine was prepared with the object of determining the effect of ring sulphur on a substance which might be expected to have narcotic properties. It was obtained by condensing α-bromodiethylacetic acid, $(C_2H_5)_2CBr.CO_2H$, with ammonium dithiocarbamate in alcohol. Diethylrhodanine (5-diethyl-2-thioketo-4-thiazolidone)



$$\begin{matrix} OC—C(C_2H_5)_2 \\ | \quad \quad > S \\ HN—CS \end{matrix}$$

crystallises in needles, m.p. 107·5° C. When injected into a rabbit intramuscularly dissolved in oil or intravenously dissolved in sodium bicarbonate solution it had a narcotic effect slightly greater than that of veronal, with a quicker recovery; given by the mouth it was inactive but when injected intravenously as an emulsion with gum arabic it immediately caused death from respiratory failure. On account of its low solubility in water it can have no practical therapeutic value.—E. H. R.

Ketones; Decomposition of aliphatic ——. A. Mailhe. Bull. Soc. Chim., 1922, **31**, 863—867.

The decomposition of mixed ketones in contact with copper-aluminium at 600° C. (*cf.* J., 1922, 727 A) was studied, the substances dealt with being methyl isopropyl ketone, methyl isobutyl ketone, methyl butyl ketone, methyl isoamyl ketone, isobutyrone, isopropyl isobutyl ketone, and œnanthone,

$$C_6H_{13}.CO.C_6H_{13}.$$

In each case the CO group is liberated almost entirely as carbon monoxide and the residues transformed into ethylenic or saturated hydrocarbons by loss or gain of hydrogen. In the case of butyl, isobutyl and heavier residues further decomposition occurs, wholly or in part, into simpler groups. Analyses of the products are given in each case and show that the substances obtained on decomposition are mainly gaseous; small changes in temperature are sufficient to affect considerably the nature of the products.—H. J. E.

Bornylene; Preparation of ——. H. Meerwein and J. Joussen. Ber., 1922, **55**, 2529—2533.

Nearly pure bornylene, solidifying point 108°—107° C. instead of 113° C. as recorded in the literature for the homogeneous substance, is prepared by the action of a 10% solution of potassium amyl oxide in amyl alcohol on bornyl chloride at 230° C. or on bornyl bromide at about 190° C. (*Cf.* J.C.S., Nov.) —H. W.

Oil of maritime pine [Bordeaux turpentine]; Constituents of ——. G. Dupont. Chim. et Ind., 1922, **8**, 549—554.

By slow fractionation of Bordeaux turpentine in a vacuum through a specially constructed column, 2 m. high, a very considerable separation into α- and β-pinene was effected. The column was provided with numerous cups of nickel gauze, each carrying a glass overflow tube of sufficiently large diameter to allow a plentiful reflux. By one fractionation a separation of 50% of α-pinene of 90% purity was achieved, and the same amount of almost pure α-pinene having α = −39·5° compared with −40·1° for the pure substance was isolated by a second distillation of the fractions first obtained by operating in such a way that a new fraction was added as soon as the calculated rotation of the residue was equal to that of the fraction about to be added. Although no break whatever was observed in the boiling point curve, a notable inflexion was obtained in the curve for the rotation when about 55% had passed over, and a fairly constant value at α = −21° was given between the approximate limits of 73 to 80%, the distillate then consisting mainly of β-pinene (nopinene). From the values obtained it was calculated that the original entire fresh turpentine contained 63% of α-pinene and 26·5% of β-pinene. The remaining 10% was represented by the last fractions boiling above 60° C. at 15 mm. pressure. The presence of these higher fractions cannot be attributed entirely to oxidation of the turpentine, and they must be regarded as normal constituents of the oil. By fractionation three main fractions were isolated. The fraction boiling at 77°—80° C. at 15 mm. was strongly dextrorotatory, and dipentene, sobrerol, and an at present unidentified strongly dextrorotatory hydrocarbon were detected in it. The fractions boiling at about 100°

—120° C. at 15 mm. appeared to consist of oxidation products, among which were a ketone, pinol, and traces of an alcohol and ester. The highest fraction consisted of a new dextrorotatory sesquiterpene, giving a crystalline nitrosite, m.p. 109°—110° C. —G. F. M.

Turpentine; Rôle of the various constituents of —— in industrial syntheses. G. Dupont. Chim. et Ind., 1922, **8**, 555—558.

In the syntheses of terpin, terpineol, and borneol from pinene the presence of nopinene (β-pinene) is actually an advantage, as it gives exactly the same products in these cases as does α-pinene, and in general in better yield and with a greater reaction velocity. The presence of the last runnings in the pinene used, is, on the other hand, very disadvantageous, and all fractions boiling higher than nopinene should therefore be eliminated. The presence of fenchol in crude synthetic terpineol and borneol is probably to be ascribed to the higher boiling constituents of the turpentine used in the synthesis, as it is nearly or entirely absent when rectified pinene is used. The formation of fenchol is certainly not due to the presence of nopinene in the starting material, as was asserted by Barbier and Grignard (J., 1909, 672). The identity of the products obtained from α- and β-pinene depends, however, on one of the two atoms or groups which are added on to the pinene molecule being a hydrogen atom; in all other cases the products would be different, and a separation of the two isomerides would be necessary in order to obtain satisfactory yields of an individual product.—G. F. M.

Silver; Oligodynamic effect of ——. R. Doerr and W. Berger. Biochem. Zeits., 1922, **131**, 351—361.

The active agent in all oligodynamic effects is the silver ion. Silver surfaces lose their activity by treatment with potassium cyanide, and water activated by silver is inactivated by potassium cyanide. The inactivation is due to conversion of the active silver ion into inactive $Ag(CN)_2$ ions. Carbon dioxide and oxygen are the constituents of the air which activate silver surfaces, each being more potent in developing activity than air itself. —H. K.

Patents.

Methane; Chlorination of ——. Holzverkohlungs-Ind. A.-G., and K. Róka. E.P. 186,270, 22.11.21.

The chlorine used in the chlorination of methane at 400°—500° C. is diluted with 2—5 vols. of steam. The degree of chlorination can be very largely controlled by varying the proportions of the reacting gases and of the steam, and catalysts, such as the chlorides of copper, iron, calcium, or magnesium can be advantageously employed. Using a quartz tube 70 cm. long and 40 mm. diam., filled with pieces of firebrick, and passing 25 l. of methane, 38 l. of chlorine, and 100 g. of steam per hour the chlorine is distributed in the reaction products as follows: 53% as HCl, 8% as CH_3Cl, 13% as CH_2Cl_2, 20% as $CHCl_3$, and 5% as CCl_4. The same amount of steam and 37 l. of both methane and chlorine give 52% as HCl, 12% as CH_3Cl, 21% as CH_2Cl_2, 14% as $CHCl_3$, and 1% as CCl_4. 41 l. of methane, 20 l. of chlorine, and 70 g. of steam give 51% as HCl, 26% as CH_3Cl, 20% as CH_2Cl_2, 1% as $CHCl_3$, and no CCl_4. —G. F. M.

Mucic acid and other products; Method of converting wood into ——. S. F. Acree. E.P. 160,777, 18.3.21. Conv., 25.3.20.

Mucic acid is produced by the oxidation of galactose, obtained from larch wood or other cellulosic material containing galactan by hydrolysis as described in E.P. 160,776 (p. 910 A). The oxidation is carried out at 50°—85° C. by means of nitric acid containing nitrogen oxides. Suitable proportions are 10% of galactose and 25% of nitric acid oxidation mixture. The crude mucic acid is purified by dissolving in ammonia to form the di-ammonium salt, clarifying the solution with animal charcoal, and re-precipitating with acid. The mother liquors from the crude acid can be used to oxidise further quantities of galactose or to hydrolyse more wood to galactose, or may be worked for other by-products such as oxalic, gluconic, and saccharic acids.—W. H. G.

Alkali salts of oxidised protalbinic acid and of oxidised lysalbinic acid as stable protective colloids for mercury compounds. M. E. Wolvekamp. U.S.P. 1,391,154, 20.9.21. Appl., 27.3.20.

The action of the alkali salts of protalbinic and lysalbinic acids (Paal, J., 1909, 996) as protective colloids is considerably improved by oxidising them with a mixture of alkali hydroxide and mercuric oxide. For the oxidised acids the names protoxalbinic acid and lysoxalbinic acid (or oxalbinic acid for a mixture of both oxidised acids) are proposed. Stable colloidal preparations of mercuric oxide, sulphide, and salicylate can be prepared with the aid of the alkali salts of the oxidised acids; these preparations can be evaporated to dryness, and the residues on treatment with water yield colloidal solutions which may be boiled without precipitation of free mercury.

Montan wax; Chlorination of ——. A. Deschauer. U.S.P. 1,429,932, 26.9.22. Appl., 22.5.22.

Chlorination is effected in an aqueous medium. —T. A. S.

Acetic anhydride; Manufacture of ——. H. Dreyfus. U.S.P. 1,430,304, 26.9.22. Appl., 24.5.21.

Acetic anhydride is prepared by treating an acetate with a pyrosulphate.—T. A. S.

Arsenobenzene derivatives; Stable —— and process of making same. W. Kolle and A. Binz, Assrs. to Farbw. vorm. Meister, Lucius, und Brüning. U.S.P. 1,431,671, 10.10.22. Appl., 20.10.21.

Arsenical preparations which are stable in solution are prepared by mixing water-soluble arsenobenzene compounds of the type, $R.NHR_1$, where R is an arsenobenzene residue and R_1 a sulphoxylate or carbamate residue, with other water-soluble arsenobenzene compounds.—G. F. M.

Acetylsalicylic acid; Proce[illegible] for obtaining the calcium salt of ——. J. Altwegg, Assr. to Soc. Chim. des Usines du Rhône. U.S.P. 1,431,863, 10.10.22. Appl., 11.1.22.

Calcium acetylsalicylate is prepared by neutralising acetylsalicylic acid with the calculated amount of calcium hydroxide in presence of a solution of sodium chloride.—G. F. M.

Lecithin; Recovery of —— from organs of cold-blooded animals. J. Grossfeld. G.P. 357,081, 6.7.18.

Dried, finely-powdered fish roe or the like is treated with organic solvents capable of extracting fat and cholesterol, *e.g.*, ether, and the residue is treated for about 3 hrs. with boiling methyl alcohol. The solution is evaporated to dryness, yielding a brown, highly viscous, colloidal product which is soluble in fats and oils, and in ethyl acetate and acetone, and which, either alone or dissolved in oils, readily forms emulsions with water. The product absorbs up to 150% I, and is suitable for the preparation of solutions of lecithin in cod-liver oil, for injection, and for use as an ointment base.—L. A. C.

Yeast and tannin; Production of compounds of ——. Farbenfabr. vorm. F. Bayer und Co. G.P. 357,140, 4.1.21.

Pressed beer-yeast mixed with water or liquefied with sodium chloride is digested with tannin or its aqueous tannin solution for several hours at 40°—50° C. After neutralisation with sodium hydroxide, the product is filtered, and the residue is washed, dried, ground, and heated to 110°—125° C. for several hours. The astringent properties of the product render it of therapeutic value.—L. A. C.

Material for the serodiagnosis of syphilis; Purification of ——. A. von Wassermann. G.P. 357,244, 27.4.20.

ANTIGENS such as alcoholic or aqueous extracts of yphilitic organs and normal organs, or lipoids, are added to human or animal blood serum which has been rendered inactive by heating to 55° C., and which shows a positive Wassermann reaction. After interaction between the antigens and material present in the serum, the product is subjected to ultra-filtration, the filtered liquid being practically ree from impurities. A normal solution for Wassermann's reaction is prepared by adding the desired quantity of the liquid antigens to a measured uantity of the liquid obtained as above, the mallest quantity which gives a complete Wassermann's reaction being a normal solution. A quantitative estimation of antigens, *i.e.*, a quantitative ontrol of the Wassermann reaction, is thus possible.—L. A. C.

4-Amino-1-phenyl-2.3-dialkyl-5-pyrazolone; Preparation of N-aminoacetyl compounds of ——. Farbw. vorm. Meister, Lucius, und Brüning. G.P. 357,752, 1.3.18.

THESE compounds are obtained by the action of aqueous ammonia on chloroacetyl-4-amino-2.3-dialkyl-1-phenyl-pyrazolones, or by the action of acids on the addition compounds of these substances with hexamethylenetetramine. For example 4-chloroacetylamino-2.3-dimethyl-1-phenyl-5-pyrazolone, m.p. 187° C., obtained by the action of chloroacetyl chloride on 4-amino-2.3-dimethyl-1-phenyl-5-pyrazolone in aqueous solution in presence of an acid-fixing substance, is mixed in chloroform solution with hexamethylenetetramine, and the addition compound which is precipitated after standing for several days is dissolved in alcohol and the solution mixed with concentrated hydrochloric acid. 4-Aminoacetylamino-2.3-dimethyl-1-phenyl-5-pyrazolone

$$C_6H_5.N\left\langle\begin{array}{l}CO——C.NH.CO.CH_2.NH_2\\ N(CH_3).\overset{\|}{C}(CH_3)\end{array}\right.$$

s thereby obtained as its dihydrochloride, an acid reacting substance which is converted into the neutral monohydrochloride by treatment with sodium ethoxide. This substance decomposes without melting at 260°—265° C. The corresponding 2-ethyl-3-methyl compound may be similarly obtained, or by the action of ammonia on 4-chloroacetylamino-2-ethyl-3-methyl-1-phenyl-5-pyrazolone, m.p. 186° C. The free bases are more soluble in water than pyramidone (dimethylaminoantipyrine). They are useful therapeutically as febrifuges.
—G. F. M.

Mercury compounds; Process of extending the catalytic activity of —— [in oxidation of acetylene]. N. Grünstein and P. Berge. U.S.P. 1,431,301, 10.10.22. Appl., 21.5.19.

SEE E.P. 143,891 of 1920; J., 1921, 368 A.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

ron as a photochemical catalyst. I. Decomposition of potassium ferrocyanide in daylight. O. Baudisch and L. W. Bass. Ber., 1922, 55, 2698—2706.

THE photochemical decomposition of alkaline solutions of potassium ferrocyanide on exposure to light may be considered to occur in two phases. The first is the change in colour from pale yellow to lemon yellow, which is reversed in the dark and which occurs in a vacuum; it is accompanied by development (reversible) of alkalinity in the solution in which the presence of active oxygen cannot be detected. The change, if protracted, leads to the separation of small quantities of colourless ferrous hydroxide. The change is represented by the scheme:—

$$\left[Fe\ \begin{array}{c}NC\\(NC)_5\end{array}\right]\begin{array}{l}K\\K_3\end{array}\xrightarrow{+H_2O+\text{light}}\left[Fe\ \begin{array}{c}NC.H\\(NC)_5\end{array}\right]\begin{array}{l}K.OH\\K_3\end{array}$$

The second phase is the hydrolytic elimination of the potassium cyanide group, which is enormously accelerated by oxygen.

$$\left[Fe\begin{array}{c}NC.H\\(NC)_5\end{array}\right]\begin{array}{l}K.OH\\K_3\end{array}\xrightarrow{H_2O}\left[Fe\begin{array}{c}OH_2\\(NC)_5\end{array}\right]K_3+HCN+KOH.$$

(*Cf.* J.C.S., Nov.)—H. W.

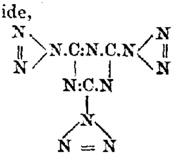
XXII.—EXPLOSIVES; MATCHES.

PATENTS.

Explosive and process of making same. E. Ott, Assr. to E. H. Faust. U.S.P. 1,390,378, 13.9.21. Appl., 25.5.20.

CYANURIC triazide,



prepared by the action of aqueous solutions of sodium azide on cyanuric halides, is claimed as an explosive. It forms colourless crystals, m.p. 94° C., is not volatile, not changed by cold water, but slowly decomposed by hot water, explodes when subjected to violent concussion, when heated to 170° C., or when heated suddenly. It is not poisonous, does not attack metals, is superior as a priming agent to mercury fulminate, lead azide, and silver azide; is suitable for the preparation of Flobert ammunition and ammunition for other small fire-arms; and in the molten state is a good solvent for most of the organic substances usually employed as explosives for grenade loadings, torpedoes, etc.—H. C. R.

Nitrating apparatus. G. Juer. U.S.P. 1,431,161, 10.10.22. Appl., 1.7.20.

The apparatus consists of a series of 16 or more nitrating pots arranged around the periphery of a rotary table to which regular increments of movement can be imparted. A centrifuge is placed adjacent to the table so as to receive the contents of the nitrating pot opposite to it when the table is at rest. An acid filling tank is also situated adjacent to the path of movement of the pots and at a distance from the centrifuge equal to the increment of movement of the table. A mechanical agitator is arranged above the path of movement of the pots with the table at a distance from the acid tank equal to a multiple of the increment of movement of the table.—G. F. M.

Explosive having liquid air as a base. G. Weber, Assr. to Soc. Les Petits Fils de F. de Wendel et Cie. U.S.P. 1,431,711, 10.10.22. Appl., 25.8.21.

An explosive is composed of liquid air, calcium silicide, and a combustible organic substance. —A. R. P.

XXIII.—ANALYSIS.

Specific gravity of small amounts of liquid; Apparatus for the rapid determination of the ——. E. Wiedbrauch. Z. anorg. Chem., 1922, 122, 167—170.

Water and the liquid in question are contained in two U-tubes which are in communication with one another and with a manometer, the heights of the liquids which balance various pressures are measured, and the specific gravity then calculated. —W. T.

Artificial daylight (Sheringham system); Application of —— to laboratory purposes. S. H. Groom. Analyst, 1922, 47, 419—423.

The correction of the light given by a gas-filled electric lamp to that of north sky light involves the elimination of progressively more energy from the blue to the red end of the spectrum. This may be accomplished either by passing the light through a suitably coloured glass screen, or by reflecting the light from a suitably coloured reflector. The latter method has been employed for the first time in the Sheringham Daylight lamp. The change produced in the appearance of coloured objects under different illuminants varies widely in different cases. If the object is one which transmits or reflects only a small portion of the spectrum, the change in colour is comparatively small. The greatest change is shown in the case of an object which reflects two widely different portions of the spectrum more strongly than the intervening portions, as in the case of a purple pigment.—H. C. R.

Daylight lamp; Use of the —— in volumetric and colorimetric analysis. W. Singleton. Analyst, 1922, 47, 424—426.

Titrations were carried out using $N/50$ solutions and a large number of the more common indicators by natural daylight, artificial daylight from an Osram "daylight" glass lamp, and the light of an ordinary vacuum electric lamp. In most cases the degree of accuracy possible in the determination of the end-point was at least as great with artificial daylight as with natural daylight. Ordinary artificial light gave uniformly less accurate titrations except when thymol blue was used as the indicator. The use of the daylight lamp also greatly increased the ease with which great accuracy could be obtained.—H. C. R.

Mixed indicators; Use of ——. A. Cohen. J. Amer. Chem. Soc., 1922, 44, 1851—1857.

The differences of subjective colour are enhanced when two indicators are partially transformed at the same hydrogen ion concentration. The colorimetric estimation of hydrogen ion concentration may, therefore, be rendered more precise by the use of suitable mixed indicators and in certain titrations sharper end points may be obtained, particularly in coloured liquids. Thus with bromothymol blue as indicator the value p_H 6·8 is indicated by a pure green colour, but in a yellow medium the colour is yellowish-green and difficult to observe; if, however, an indicator is added which is violet at this concentration, then the total effect of the mixed indicators will be a green end point. This may be achieved by adding equal quantities of bromothymol blue and bromocresol purple. Several examples of the use of mixed indicators are described.—J. F. S.

Sulphuric acid; Estimation of —— as barium sulphate in the presence of aluminium. L. Moser and P. Kohn. Z. anorg. Chem., 1922, 122, 299—310.

The results of the estimation of sulphuric acid as barium sulphate in the presence of aluminium are too low, owing to the adsorption of aluminium sulphate by the barium sulphate. The amount adsorbed increases at first with the concentration of the aluminium salt but soon reaches a limit. The error is only one-tenth of that observed in corresponding determinations in the presence of ferric salts. The best results were obtained in hydrochloric acid solutions, where the maximum error was found to be −0·15%.—W. T.

Calcium; Estimation of small quantities of ——. P. P. Laidlaw and W. W. Payne. Biochem. J., 1922, 16, 494—498.

The method described is suitable for estimating calcium in amounts of the order of 0·1 mg., and gives results accurate to about 0·002 mg. The calcium is precipitated as oxalate (in the case of blood serum, this may be done directly from the serum without previous incineration). After separation, the precipitate is dissolved in hydrochloric acid and the calcium re-precipitated in the form of calcium alizarinate by the addition of excess of alizarin in alcoholic solution, and, after warming, of a few drops of strong ammonia. When crystalline, the precipitate is collected in a Gooch crucible, washed with dilute ammonia, and decomposed with a solution of oxalic acid in 50% alcohol. The liberated alizarin is dissolved in 95% alcohol, made just alkaline with ammonia, and estimated colorimetrically by comparison with a standard solution of ammonium alizarinate.—E. S.

Copper; Microchemical estimation of ——. G Spacu. Bul. Soc. Stiinte Cluj, 1922, 1, 296—301 Chem. Zentr., 1922, 93, IV., 737—738.

The green compound described previously (J., 1922 881 A) is precipitated in a double separating funne in which the upper and lower compartments hol 35 c.c. and 5 c.c. respectively. After precipitation, the solution is shaken three times with 2 c.c chloroform in the upper compartment, and the loroform, after settling, is run into the lower npartment, whence it is drained into a porcelain ucible. The chloroform is evaporated *in vacuo* in lesiccator, and the precipitate is either weighed $CuPy_2(CNS)_2$, or is converted into cupric oxide sulphide before weighing.—L. A. C.

ductions with cadmium in volumetric analysis. II. W. D. Treadwell, M. Blumenthal, M. Stärkle, M. Hooft, M. Dreifuss, and A. Bossi. Helv. Chim. Acta, 1922, 5, 732—743.

NTINUING previous work (J., 1921, 605 A) it is own that when uranyl salts are reduced with ely divided zinc or cadmium, reduction is inclined go beyond the uranous stage to the U''' stage. is may be corrected by allowing the solution from e reduction tube to fall drop by drop into a vessel posed to the air, when the trivalent uranium is idised to the uranous stage. It can then be trated accurately with permanganate. To prent oxidation of the uranous salt to the uranyl age by air, the solution should be fairly strongly id, about 3·0 N sulphuric acid being convenient. the electrometric method of titration is used, er-reduction can be ignored, since the distance tween the two breaks in the curve gives the titre. or technical purposes the over-reduction is so ight when cadmium is used that, for estimating all quantities of uranium in very dilute solution, can be ignored. Titanium and uranium can be timated together in dilute solution by reduction ith cadmium and electrometric titration with peranganate in an atmosphere of carbon dioxide. By e same method small quantities of titanium can determined in presence of large quantities of on, using potassium bichromate for the titration. anadic acid is reduced quantitatively to the V'' age if air is carefully excluded, and the reduced lution can be titrated with permanganate. It is st to run the reduced solution direct into the idified permanganate (a quantity within 0·5 c.c. that necessary) previously freed from air. ndigo can be estimated by dissolving in sulphuric cid monohydrate at 70° C., cooling and diluting ith water to give a solution 0·05 to 0·01N with espect to indigo and 0·2 to 0·5N with respect to lphuric acid. The solution is then reduced to the uco stage by running through a reduction ube (about 7—8 cm. by 1·8 cm.) filled with nely divided cadmium. The reduced solution is llected in an atmosphere of carbon dioxide and trated with ferric chloride electrometrically. The egree of accuracy is very high. Thioindigo and ethylene Blue can be estimated in a similar maner. (*Cf.* J.C.S., Nov.)—E. H. R.

eductions with cadmium and lead in volumetric analysis. III. W. D. Treadwell, P. Hristic, L. Egger, P. Sturzenegger, A. Freuler, A. Weber, and R. F. Edelmann. Helv. Chim. Acta, 1922, 5, 806—818.

HE cadmium reduction tube previously described ., 1921, 605 A) can be used for the reduction of lorate in dilute sulphuric acid solution. The sulting solution of chloride is then titrated with ver nitrate by the Volhard method. Perchlorate not reduced under these conditions, consequently lorate can be determined in presence of perlorate. The latter can be reduced to chloride by iling in sulphuric acid solution (about 10 c.c. of ncentrated acid to 50 c.c. of $N/10$ perchlorate soluon) in presence of titanium sulphate with finely vided cadmium for ½ to 1 hr. A small amount cadmium sulphide which is formed does not terfere. After cooling, the solution is diluted d the titanous sulphate present is oxidised with rmanganate. The chloride is then titrated with ver nitrate either electrometrically or by the Volhard process. For the reduction of niobic acid, followed by titration with permanganate, Metzger and Taylor reduced with amalgamated zinc a sulphuric acid solution of niobic acid stabilised with succinic acid (*cf.* Taylor, J., 1909, 818). It is shown that this solution is far from stable; it gradually becomes opalescent and in course of time its reducibility diminishes. The reducibility of a niobic acid solution depends on the degree of dispersity of the colloidal particles of the acid. The most consistent results were obtained with a solution of the fluoride in concentrated hydrochloric acid. After removal of hydrofluoric acid the solution was passed through a cadmium reduction tube, and then titrated electrometrically with ferric chloride. Although the results were consistent, it does not appear that reduction was carried completely to the Nb''' stage. Molybdate can be reduced quantitatively to the Mo''' stage in hydrochloric acid solution, and stannic chloride to the stanous stage, by finely divided lead. The reduced solutions were titrated with permanganate after addition of manganous sulphate. The lead was prepared by immersing a zinc rod in acidified lead acetate solution, washing the lead crystals formed with alcohol and ether and drying in a vacuum. The material so obtained was used in a reduction tube.—E. H. R.

Manganese; New method for the estimation of ——. S. Minovici and C. Kollo. Chim. et Ind., 1922, 8, 499—500.

MANGANESE may be accurately estimated, even when present in very small quantities, by precipitation as iodate by means of iodic acid, according to the equation

$$MnSO_4+2HIO_3=Mn(IO_3)_2+H_2SO_4.$$

A solution of about twice the theoretical quantity of iodic acid is added to the manganese solution, and after warming for 10 mins. on a water bath, twice the volume of alcohol is added. After a short time the precipitate settles down, and is collected on a filter or Gooch crucible and washed with 70% alcohol, preferably saturated with manganous iodate. The washed precipitate is dried at 100° C., and weighed. The mother liquors contain no trace of manganese, as the iodate is insoluble in 70% alcohol in presence of excess of iodic acid. In water at ordinary temperatures the solubility of the iodate is 0·195%, and in 70% alcohol 0·005%. The absolute percentage error in the examples given varied from 0·16 to 0·63% when quantities of the order of 0·1—0·3 g. of the hydrated sulphate were taken for estimation.

—G. F. M.

Precipitations with hydrogen sulphide; Hindrance of —— by neutral chlorides. L. Dede and P. Bonin. Ber., 1922, 55, 2327—2331.

THE precipitation of lead sulphide from 1/1000 molar solutions of lead chloride in water by hydrogen sulphide at 20° C. is completely inhibited by the presence of hydrochloric acid in a concention of 1·4N. In the presence of increasing concentrations of calcium, ammonium, or potassium chloride, decreasing concentrations of hydrochloric acid are sufficient to suppress precipitation entirely. Incomplete precipitation of lead sulphide is observed with considerably lower concentrations of hydrochloric acid. At higher temperatures, the effect of hydrochloric acid in the presence of neutral chlorides is still more marked. Similar results to those obtained with lead choride are also obtained with cadmium salts and apparently with tin salts. The precipitation of lead sulphide is hampered to a less degree by the presence of perchloric acid. In this case the addition of sodium perchlorate favours precipitation presumably by depressing the dissociation of the acid. The precipitation of lead chromate from acetic acid solution is incomplete in the presence of much chloride; in ammoniacal solution this is not the case.—H. W.

Iodometric method; New —— based on the formation and the estimation of cyanogen iodide. R. Lang. Z. anorg. Chem., 1922, 122, 332—348.

A volumetric method for the estimation of iodides is given based on the fact that an iodide will react with an oxidising agent ($\mathrm{KMnO_4}$) and hydrocyanic acid in the presence of hydrochloric and sulphuric acids to give cyanogen iodide, the end point being indicated by starch solution. This can be controlled by estimating the cyanogen iodide with thiosulphate

$$\mathrm{ICN}+\mathrm{S_2O_3}''+\mathrm{H}^{\cdot}\rightarrow\mathrm{I}'+\mathrm{S_4O_6}''.$$

The method is applicable in the presence of bromides and nitrates and can also be employed for the determination of the different stages of oxidation of iodine in mixtures. The reactions of hydrocyanic acid with iodine mono-chloride and hypoiodous acid have also been investigated.
—W. T.

Patent.

Flash point of oils; Apparatus for determining ——. F. H. M. Klee. E.P. 185,814, 3.6.21.

The oil to be tested is contained in a vessel surrounded by an electrically heated water jacket. A stirrer is provided for the oil and the vapours above it. Ignition is effected by a spark or a coil heated to redness. The top of the vessel can be removed for open cup tests. A modification consists of an electrically heated vessel into which high-boiling oils of high flash-point may be dropped to determine their ignition temperature in the presence of heated air or oxygen.—T. A. S.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given; they are on sale at 1s. each at the Patent Office, Sale Branch, Quality Court Chancery Lane, London, W.C. 2, 15 days after the date given.

I.—GENERAL; PLANT; MACHINERY.

Applications.

Algem. Norit Maatsch. Compression, storage, and treatment of gases. 30,724. Nov. 10. (Holland, 14.11.21.)

Algem. Norit Maatsch. Drying gases. 30,725. Nov. 10. (Holland, 14.11.21.)

Algem. Norit Maatsch. Treating liquids. 30,726. Nov. 10. (Holland, 14.11.21.)

Arbuckle. Means for separating liquid and soli components of mixtures. 30,318. Nov. 6.

Baker. Regenerative furnaces. 29,409. Oct. 27.

Barnes and Fleming. Grinding mills. 28,846 Oct. 24.

Boberg, Söderlund, Testrup, and Techno Chemical Laboratories. Separating solids from liquids. 30,014 and 30,700. Nov. 2 and 9.

Bräuer. Cooling fluids. 30,233. Nov. 4.

Brinjes and Goodwin, and Seaman. Grinding mixing, etc. mills. 28,977. Oct. 24.

Broadbent and Sons, and Sturgeon. Centrifuga separators. 30,509. Nov. 8.

Chemical Engineering Co., and Spensley. Producing intimate mixtures of substances and obtaining chemical products. 29,728. Oct. 31.

Griffiths and Passburg. Obtaining large crystals from solutions. 29,064. Oct. 25.

Heenan. Drying air and gases. 29,767. Oct. 31.

Henshaw, Whittell, and Holmes and Co. Apparatus for bringing liquids and gases into intimate contact. 30,346. Nov. 7.

Kirke. 30,689. *See* XIX.

Lehane and Ruck. 30,764. *See* II.

Nitrogen Corp. Drying gases. 29,792. Oct. 31. (U.S., 9.11.21.)

Porteus. Mixing-machines for granular or pulverulent substances. 30,168. Nov. 4.

Raper. Drying-machines. 28,869. Oct. 24.

Sklenar. Reverberatory furnace. 30,649. Nov. 9.

Smidth and Co. (Smidth & Co.). Ball and tube mills. 30,538. Nov. 8.

Soc. des Condenseurs Delas. Evaporating, concentrating, distilling, etc. apparatus. 28,971. Oct. 24. (Fr., 21.7.21.)

Techno-Chemical Laboratories, and Testrup. Rotatable heat-transmitting appliances. 29,239. Oct. 26.

Tooth. Treatment of smoke and fumes. 28,842. Oct. 24.

Vallez. Coating filtering-frames. 29,168. Oct. 26.

Wade (Standard Development Co.). Manufacture of foam-forming liquids. 30,487. Nov. 7.

Weston. Gyratory crushers. 30,486. Nov. 7.

Complete Specifications Accepted.

11,972 (1921). Paterson. Filtering apparatus. (187,259.) Nov. 1.

12,048 (1921). Thompson (Sharples Specialty Co.). Centrifugal emulsifiers. (187,642.) Nov. 8.

13,206 (1921) and 6593 (1922). Rigby. Heatin or cooling liquids or admixed solids and liquids i evaporative or like treatment. (187,260.) Nov. 1

14,147 (1921). Weddingen. Removing incrustations from boilers and softening feed-water (187,647.) Nov. 8.

17,017 (1921) and 8186 (1922). Meek. Furnaces (187,657.) Nov. 8.

19,220 (1921) and 11,748 (1922). Marr, and Cok Oven Construction Co. Continuous drying pulverulent materials, applicable to the manufacture of neutral ammonium sulphate. (187,320 Nov. 1.

19,848 (1921). Paterson. Filtering apparatu (187,708.) Nov. 8.

20,147 (1921). Thatcher. Manufacture of sem permeable separators such as diaphragms, diffusio walls, etc. (187,728.) Nov. 8.

20,158 (1921). Kestner. Washing and displac ment of gases. (168,867.) Nov. 15.

20,414 (1921). Davis. Filters. (188,059.) Nov. 1

21,659 (1921). Roth. Separation of fine materi (187,381.) Nov. 1.

25,393 (1921). Chem. Fabr. Griesheim-Elektro and Sander. Apparatus for washing material whi has been separated by centrifugal action. (187,42 Nov. 1.

27,176 (1921). Pomeroy. Pulverising-apparat (188,173.) Nov. 15.

30,096 (1921). Silver Springs Bleaching and Dyeing Co., and Hall. Treating certain waste liquors. (188,208.) Nov. 15.

33,507 (1921). Bamburg. Grinding or crushing machines. (187,884.) Nov. 8.

33,810 (1921). Schnetzer. Preventing formation of scale in boilers, evaporators, etc. (174,905.) Nov. 1.

33,938 (1921). Harvey and Buckley. Centrifugal drying-machines. (188,243.) Nov. 15.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Applications.

Beilby. Hydrogenation of hydrocarbon oils and residues. 30,655. Nov. 9.

Boocock, Laing, and Nielsen. Manufacture of fuel briquettes etc. 29,384. Oct. 27.

Butler. Manufacture of liquid fuel. 29,789. Oct. 31.

Capon (Wells). Gas-producers. 30,550 and 30,552. Nov. 8.

Capon (Wells). Apparatus for cooling and cleaning gas. 30,551. Nov. 8.

Coley. Gas manufacture. 30,773. Nov. 10.

Diehl. Recovery of coal from waste by flotation. 29,522. Oct. 28. (Ger., 3.11.21.)

Edison Swan Electric Co., and Percival. Manufacture of metallic filaments for incandescent electric lamps etc. 28,805. Oct. 23.

Ferguson. Feldspar tanks for coal-washing. 30,374. Nov. 7.

Gas Research Co. Gas generators. 30,678. Nov. 9. (U.S., 20.6.22.)

Hollinshead. Briquette fuel. 28,719. Oct. 23.

Kirke. Water-gas plants. 29,068. Oct. 25.

Lamplough. Treatment of hydrocarbon-bearing substances. 30,746. Nov. 10.

Lehane and Ruck. Manufacture of retorts etc. 30,764. Nov. 10.

Lewis. Burning blast-furnace gas in steam boilers. 29,464. Oct. 28.

Lockwood. Treating coal etc. 29,111. Oct. 25.

Loriette. Production of liquid-fuel mixtures with alcohol as basis. 30,106. Nov. 3. (Fr., 3.11.21.)

Mann. Suction-gas producers. 30,453. Nov. 7.

Merz. Fuels. 28,963. Oct. 24.

Monnot. Cracking oils. 29,383. Oct. 27.

Oddy. Distilling coal, peat, wood, etc. 29,469. Oct. 28.

Oddy. Purifying etc. hydrocarbons etc. 29,470 and 29,472. Oct. 28.

Oddy. Light hydrocarbons etc. for motors and lighting. 29,471. Oct. 28.

Peebles. Instrument for indicating heating quality of gas. 30,182. Nov. 4.

Rideal. Elimination of sulphur from oil. 30,837. Nov. 10.

Southgate. Apparatus for distilling and testing carbonaceous matter. 28,768. Oct. 23.

Sumner. Manufacture of gas. 29,368. Oct. 27.

Wellman Seaver Morgan Co. Gas-producers. 30,899. Nov. 11. (U.S., 12.11.21.)

White. Treatment of petroleum etc. 29,240. Oct. 26.

White. Low-temperature carbonisation of carbonaceous material etc. 29,241. Oct. 26. (India, 18.1.22.)

Wood. Gas retorts. 30,919. Oct. 11. (Australia, 30.11.21.)

Complete Specifications Accepted.

32,120 (1920). Parker and Bamber. Gas-scrubbers. (187,999.) Nov. 10.

11,419 (1921). Accioly. Manufacture of an alcoholic liquid for use as combustible. (187,640.) Nov. 8.

13,633 (1921). West, Madden, Boardman, and West's Gas Improvement Co. Destructive distillation of coal and like carbonaceous materials. (187,263.) Nov. 1.

16,554 (1921). Turner. Gas-generators. (187,277.) Nov. 1.

16,826 (1921). Marlow. Gas-producers. (187,282.) Nov. 1.

17,352 (1921). Meguin A.-G. Butzbach, and Müller. Apparatus for carbonising bituminous substances, such as coal or shale, at low temperature. (168,859.) Nov. 8.

17,587 (1921). Markham, and Staveley Coal and Iron Co. Distillation of solid carboniferous matter. (188,019.) Nov. 15.

17,873 and 20,740 (1921). Reid. Manufacture of gaseous fuel from lime-kiln gases. (188,022.) Nov. 15.

19,327 (1921). Giles (Field). Fuel for internal combustion engines. (187,326.) Nov. 1.

19,355 (1921). Illingworth. Production of smokeless fuel and coke. (187,328.) Nov. 1.

19,463 (1921). Blake. Alcohol fuels. (187,335.) Nov. 1.

19,525 (1921). Roberts. Carbonisation of coal. (187,336.) Nov. 1.

20,412 (1921). Tinker. Production of petrol. (188,058.) Nov. 15.

20,444 (1921). Franklin and Pettingall. Fuel. (187,351.) Nov. 1.

20,612 (1921). Young. Manufacture of gas. (188,073.) Nov. 15.

26,482 (1921). Koppers Co. Purification of gases. (170,572.) Nov. 8.

28,399 (1921). Dempster, Ltd., and Broadhead. Gas purifiers. (188,193.) Nov. 15.

33,441 (1921). Scheib and Koch. Manufacture of pure nitrogen-carbonic-acid mixtures from combustion gases. (172,958.) Nov. 1.

III.—TAR AND TAR PRODUCTS.

Applications.

Chem. Engineering and Wilton's Patent Furnace Co., and Shadbolt. Distillation of tar. 29,110. Oct. 25.

Humphrey and Humphrey. Boilers for pitch, tar, etc. 28,745. Oct. 23.

IV.—COLOURING MATTERS AND DYES.

Applications.

Burt, Boulton, and Haywood, and Miles. Manufacture of indophenolic bodies. 29,258. Oct. 26.

Imray (Soc. Chem. Industry in Basle). Manufacture of azo dyestuffs and chromium compounds thereof. 30,923. Nov. 11.

Plauson's (Parent Co.), Ltd. (Plauson). Dyes etc. 29,321. Oct. 27.

Complete Specification Accepted.

23,286 (1921). Ransford (Cassella u. Co.). Manufacture of salts of acridinium compounds. (188,127.) Nov. 15.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Applications.

Brooke, Brooke, and Stapleton. Manufacture of paper etc. 29,481. Oct. 28.

Carbone, and Instituto Sierioterapico Milanese. Preparing cultures of *Bacillus felsineus.* 30,912. Nov. 11. (Ital., 12.11.21.)

Davies and Haig. 30,482. *See* VI.

Dreaper. Manufacture of viscose silk etc. 30,214. Nov. 4.

Fries. Manufacture of water-resisting paper. 29,491. Oct. 28. (Jugo-Slavia, 29.10.21.)

Hydroloid, Ltd. (Exportingenieure f. Papier u. Zellstofftechnik Ges). Washable printing papers. 29,054. Oct. 25.

Hydroloid, Ltd. (Exportingenieure f. Papier u. Zellstofftechnik Ges). Treatment of asbestos materials. 29,059. Oct. 25.

Hydroloid, Ltd. (Exportingenieure f. Papier u. Zellstofftechnik Ges). Water- and fire-proof paper. 29,060. Oct. 25.

Levy. Production of artificial filaments. 29,254. Oct. 26.

Levy. Manufacture of cellulose acetate. 30,136. Nov. 3.

Medhurst. Manufacture of paper. 29,245. Oct. 26.

Moriondi. Manufacture of viscose silk. 29,965. Nov. 2.

N. V. Nederlandsche Kunstzijde Maatsch. Purifying solutions of viscose etc. 30,577. Nov. 8. (Holland, 18.11.21.)

Nobel Industries, Ltd. 29,092. *See* XXII.

Ros, and Volos Manufacture, Ltd. Treating fibrous materials. 28,932. Oct. 24.

Schidrowitz. Manufacture of paper etc. 29,885. Nov. 1.

Schmitt. Cleaning cotton fibre etc. 29,460. Oct. 28.

COMPLETE SPECIFICATIONS ACCEPTED.

11,293 (1921). Dreyfus. Manufacture of cellulose derivatives. (187,639.) Nov. 8.

20,116 (1921). Ishizu. Treatment of ramie, china grass, etc. in the production of yarn or thread. (188,037.) Nov. 15.

20,195 (1921). McGill, and Volos Manufacture, Ltd. Treatment of fibrous materials. (187,346.) Nov. 1.

*22,609 (1921). Wade (Internat. Cotton Protecting Co.). Impregnated cotton bales. (187,394.) Nov. 1.

25,435 (1921). Kumagae and Chiba. Recovery of material for the manufacture of paper. (187,805.) Nov. 8.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

APPLICATIONS.

Davies and Haig. Scouring, bleaching, dyeing, etc. wool etc. 30,482. Nov. 7.

Grant. Waterproofing textile fabrics. 30,460. Nov. 7.

Levy. Dyeing artificial filaments. 30,135. Nov. 3.

Marsden. Treatment of fabrics. 29,242. Oct. 26. (U.S., 27.2.22.)

Newell. Dyeing animal and vegetable fibre. 29,462. Oct. 28.

Plauson's (Parent Co.), Ltd. (Plauson). Dyeing. 28,881. Oct. 24.

Soc. Anon. dite Progil. Mordant for dyeing animal fibres. 30,027. Nov. 2. (Fr., 30.8.22.)

COMPLETE SPECIFICATIONS ACCEPTED.

18,817 (1921). Gott and Wallis. Apparatus for dyeing or bleaching textiles. (187,669.) Nov. 8.

29,044 (1921). Akt.-Ges. f. Anilinfabr. Dyeing animal or mixed fibres. (171,981.) Nov. 1.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

APPLICATIONS.

Appareils et Evaporateurs Kestner. Extracting sodaic salts from bicarbonated mineral waters. 30,103. Nov. 3. (Belg., 5.11.21.)

Carmichael and Co., and Guillaume. Apparatus for manufacture of sulphuric acid. 30,632. Nov. 9.

Charity. Utilisation of waste lime from chemical works. 30,407. Nov. 7.

Chem. Fabr. Griesheim-Elektron. Production of stable compounds of calcium hypochlorite. 30,593. Nov. 8. (Ger., 8.11.21.)

Fowler and Subrahmaniam. Production of acetic acid from alcohol. 29,625. Oct. 30.

Freundler. Treatment of seaweed. 28,970. Oct. 24. (Fr., 25.10.21.)

Gerber. Dissociation of aluminiferous substances in combination with fixation of nitrogen. 30,133. Nov. 3.

Haynes and Williams. Fixation of nitrogen. 30,000. Nov. 2.

Jaques and West. Manufacture of ammonium compounds. 29,532. Oct. 28.

ABSTRACTS*

I.—GENERAL; PLANT; MACHINERY.

Humidity equilibria of various common substances. R. E. Wilson and T. Fuwa. J. Ind. Eng. Chem., 1922, 14, 913—918.

DATA, expressed in the form of curves, concerning the humidity equilibria of various common substances are discussed. In the determination of these data, each substance, in a finely divided state, was brought to equilibrium by successively exposing for 18 to 96 hrs. to a current of air of 15, 30, 50, 70, 90, and 100%, and then of 90, 70, 50, 30, and 15% relative humidity at 25° C. Equilibrium in each case was thus approached from both the saturated and unsaturated state of the substance. In most cases, the dry weight, found by passing air, previously dried by means of phosphorus pentoxide, over the substance heated to 50° C., agreed closely with the weight found after drying in an oven at 105°—110° C. All the curves have the same general shape, the water content of each substance rising rapidly in air having a high or low humidity, and slowly in air of 20 to 60% relative humidity. Wool, jute, and silk have a greater affinity for moisture than cotton and linen. Absorbent cotton has a very high affinity for moisture. Cellulose acetate silk retains less moisture than viscose, nitrocellulose, and natural silks, which have similar affinities for moisture. The moisture content of paper increases with an increase of lignin content. Foodstuffs have a high affinity for moisture, and tobacco and leather retain more moisture than any other substance examined. Carbon black and lampblack have similar affinities for moisture but are much inferior to activated charcoal and unheated gelatinous silica as absorbents for moisture. Finely divided inorganic substances such as kieselguhr, kaolin, asbestos, and glasswool, have characteristic low absorptive capacities for moisture. The increased drying effect of warm air is chiefly due to the resulting decrease of its relative humidity, and the moisture contents of substances, exposed over the ordinary range of indoor and outdoor temperatures, changes but slightly provided that the relative humidity of the surrounding air is constant.—A. J. H.

Materials of low thermal conductivity. E. Griffiths. Faraday Soc., 16.10.22. [Advance proof.]

THE ideal material for use as an insulator from a cold-storage engineer's point of view is stated to consist of a light substance, having an assemblage of minute cells enclosed in a framework which is impervious to moisture, since water has a very high thermal conductivity and is liable to set up decomposition in substances of organic origin. The paper gives the results of a series of investigations carried out on expanded rubber (a rubber converted into a highly cellular form and having an exceedingly low density), balsa wood (a very light wood obtained from Ecuador), the fibrous waste from a tree known as "*Kingia Australis*," mats made from cured eel grass sewn between sheets of strong paper, and compressed peat, with a view to ascertain if these materials would be suitable for cold-storage insulation. The values found for the thermal conductivity, expressed in B.Th.U. per sq. ft. per hr. for 1 in. thickness and 1° F. difference in temperature, were:—expanded rubber clippings, 0·342 and 0·308 for packing densities of 2·6 and 4·0 lb. respectively per cub. ft.; balsa wood, 0·329 and 0·377 for 2-in. boards weighing 5·75 and 8·6 lb. respectively per cub. ft.; *Kingia* wood waste, 0·339 for a packing density of 8·4 lb. per cub. ft.; eel grass mats, 0·316 and 0·341 for packing densities of 9·4 lb. and 13·4 lb. respectively per cub. ft.; compressed peat, 0·512 and 0·502 for specimens weighing 20 lb. and 29·5 lb. respectively per cub. ft. Before an opinion can be expressed on the merits of expanded rubber or eel grass mats the author considers that a long period test under service conditions will be required, and points out that the thermal conductivities of insulating materials in general are not invariable physical constants.

—S. G. U.

Pseudo-extraction; Winkelblech's phenomenon or ——. New methods of extracting solids. K. Charitschkov. J. Russ. Phys.-Chem. Soc., 1920, 52, 96—107.

WHEN certain pseudo-solutions, such as those of gelatin, agar-agar, and sodium oleate, are treated with various non-aqueous solvents insoluble in water, the solid disperse phase passes, partially or completely, into the liquid, non-aqueous phase in the form of a gel. It is suggested that this phenomenon, to which is given the name "pseudo-extraction," may find technical application in such operations as soap boiling and the extraction of gelatin and glue from jellies. (*Cf.* J.C.S., Dec.)

—T. H. P.

Liquid films formed on solid surfaces under dynamic conditions; Thickness of ——. Research Staff of General Electric Co., London (F. S. Goucher and H. Ward). Phil. Mag., 1922, 44, 1002—1014.

THE thickness of the film is dependent on the shape of the solid on which it is formed. For a flat slab of infinite thickness the relationship between the thickness (t), gravity (g), the viscosity (η), density (ρ), and velocity of drawing (v_e) is $t^2 = 2v_e\eta / \rho g$. If the solid is in the form of a fine wire of radius, r, the surface tension is dominant, and gravity negligible. In this case, $t/r = 4{\cdot}8\eta v_e/\gamma$, where γ is the surface tension. These equations apply to suspensions if the diameter of the particles does not exceed the thickness of the film. If the liquid wets the surface, the solid does not exert any specific action.—W. E. G.

Discharge of air through small orifices, and entrainment of air by the issuing jet. J. S. G. Thomas. Phil. Mag., 1922, 44, 969—988.

AN investigation into the effect of variation in the diameter of orifice and length of channel of downwardly directed jets, on the rate of flow and on the entrainment of air. The variation in the rate of discharge with the gas pressure can be represented by the equation $Q = A'e^{\alpha}$, where A′ and α are constants. In the case of thin discs, with orifices of diameter not less than three times the thickness of the plate, the discharge of air is given by the formula, $v_e{}^1 = {}^{509}d^{1\cdot892}\ e^{0\cdot483}$. With thick discs, as the diameter of the channel decreases, the value of α increases. For low pressures, the volume of air entrained increases linearly with the gas pressure, followed by a subsequent increase at a continuously decreasing rate. Anomalous behaviour is observed with thick discs. The jet becomes unstable over a certain range of pressures, the volume-pressure curve showing an inflexion. This instability is clearly demonstrated when the volume of air entrained per unit of air of the issuing jet is plotted against the pressure of the gas. A diminution in the size of the orifice is accompanied by a greater air entrainment up to a critical value of the diameter, at which point turbulence is impressed on the gas on entering the orifice. With decreasing diameter and constant length of channel the disturbance increases, but with

Absorption and purification of gases and vapours. R. Adler. E.P. 165,451, 27.6.21. Conv., 28.6.20.

The gaseous substances on entering the absorption or purifying chamber, instead of coming in contact with atomised sprays of liquid, are made to flow between sheets of liquid arranged at convenient distances apart. These sheets are broken at suitable places to permit the gas to flow from the space below to the space above the sheet. With chambers of square or rectangular cross-section the liquid issues as thin continuous sheets from a set of horizontal parallel pipes fixed on or near the side walls of the chamber. The issuing pressure is such that each sheet can completely span the chamber. Passages for the gas across the sheets are made by suitably placed projections fixed a short distance from the opposite wall. Sometimes a second set of pipes is mounted on the opposite wall, in such a manner that sheets of liquid from them flow in the opposite direction to, and between the sheets issuing from, the first set. In this case each pipe is fitted with a guard placed between the pipe and the wall and so arranged that the sheet of liquid issuing from the opposite pipe immediately above meets the outer surface of this guard tangentially and then falls as a continuous sheet to the bottom of the chamber. The space between the guard and the pipe forms the passage through which the gas flows in passing from the lower to the upper gas space. In the cylindrical type of chamber the liquid is introduced through a central pipe which is fitted with a number of annular slotted nozzles which produce a series of parallel sheets of liquid. Adjustable pins can be fixed so that each sheet can be broken at a suitable point and communication thus provided between the spaces above and below the sheet.—S. G. U.

Corrosion in evaporating and distilling apparatus; Method of and means for preventing ——. Akt.-Ges. Kummler und Matter. E.P. 166,129, 4.7.21. Conv., 7.7.20.

The presence of minute traces of acids in the vapours from evaporators produces a large amount of corrosion, especially in pumps, compressors, etc., and it is proposed to make these vapours alkaline, not, as hitherto suggested, by neutralising the solutions to be concentrated, but by neutralising the vapours given off by the acid solutions. This is done by introducing the alkali in an atomised state either into the steam space of the evaporators, or at an intermediate point between the evaporator and the pump, or at the pump or compressor. For thorough mixing baffle plates are usually provided in the mixing chamber and provision is made for the return of the excess of alkali to the alkali feed tank. When it is known that a salt solution of a certain concentration produces vapours of an acid reaction and at another degree of concentration vapours of an alkaline nature, the invention provides for a thorough mixing of these vapours, without the further addition of alkaline substances.—S. G. U.

Lixiviation; Method of and apparatus for ——. **R. Adler. E.P. 166,525, 2.7.21. Conv., 13.7.20.***

The material to be lixiviated by solvents, with the addition of gases if desired, is fed into the charging hopper, a, from which it passes by a small **worm conveyor into the container, l,** which is **provided with an outlet, o, to permit of the** escape **of the displaced air or unabsorbed gases.** The **bottom of this container is connected to the** upper **end of the highest of three inclined tubes, b,** which are connected at their adjacent ends by trunks, c, and are provided with worm conveyors which can be adapted to permit of heating the material as it passes through the tubes if desired. The material after passing in turn through each of these three reaction tubes is discharged at the lowest point of the third tube into the lowest point of a fourth inclined tube, f, also fitted with a worm conveyor, which finally ejects the lixiviated material at g. The solvent is fed into the top of the tube, f, through h, and the gases are introduced into the lowest tube, b, by the pipe, k. The final separation of the gas from the solvent is effected in j. Any gas which is not absorbed by the solvent or is produced during lixiviation ultimately enters l and is carried off through o.—S. G. U.

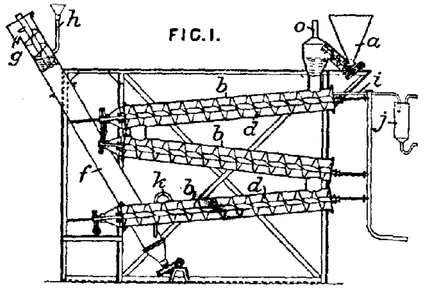

FIG. I.

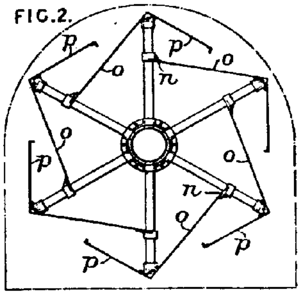
Drying systems. S. Buxton. E.P. 186,370, 2.5., 11.5. and 13.6.21.

Hot gases from boilers are delivered by a special flue into the first of a series of chambers in which the dryers are erected. Through these they may flow in turn either parallel to or across the axes of the drying tubes. With stationary dryers these chambers are usually provided with tubes to heat the air admitted to the dryers. With the rotary type the gases after leaving the chambers enter another chamber containing pipes through which the air is circulated, and then pass through another chamber containing an economiser before entering the chimney. When the material to be dried gives off obnoxious vapours, the air and vapours after leaving the dryers, pass to a condenser, and after the condensation of the moisture the air is discharged into the boiler furnace. If deodorisation is unnecessary the hot air and vapours can be discharged directly into the atmosphere. The drying chambers may be either stationary or rotary. In both cases each chamber consists of two coaxial shells forming a closed annular space which is itself totally surrounded by the chamber through which the flue gases pass. Boiler steam is admitted to this annular space, any condensed steam being removed by suitable devices at the lower end of the drying tubes. The stationary type of dryer is fitted with a worm conveyor, and the inner surface of the rotary tube type with a series of blades, to convey the material from the higher (the charging) to the lower (the discharging) end of the dryer. A centrally placed steam pipe provided with radial branches conveys steam to the annular space in the rotary type of dryer. The dryers are given a slight inclination and provided at each end with covers to which are attached the gears for admitting the wet and removing the dried material, and the pipes for admitting and withdrawing the air used. This hot air passes through the dryer in the opposite direction to the material. —S. G. U.

Drying apparatus. P. Scrive. E.P. 186,548, 28.12.21.*

A rotary drying apparatus is constructed of plates, o, p, which form the walls and buckets of a rotating prism, one form of which is shown in sectional view in the figure. The drying gases are withdrawn through the hollow shaft.—B. M. V.

FIG. 2.



Drying apparatus. J. E. Bolling, Assr. to Drying Systems, Inc. U.S.P (a) 1,431,145 and (b) 1,431,146, 10.10.22. Appl., 20.4.18 and 6.6.19.

(a) A fan is arranged to blow a current of air through a heater into the drying chamber, from which it enters a pipe communicating with the suction of the fan. This pipe is provided with an inlet and an outlet branch, each of these branches and the pipe itself being fitted with dampers, coupled together so that they can be operated simultaneously. The pipe damper is placed between the inlet and the outlet branches and operates in the opposite direction from the dampers in these branches. A thermostatic control placed between the drying chamber and the pipe damper adjusts the positions of the dampers in accordance with the fall in temperature in the drying chamber. (b) In a similar plant to that described above, the thermostatic motor is placed between the inlet pipe and the fan, and has connexions for adjusting the dampers according to the temperature changes in the conduit near the motor.—S. G. U.

Crushing or reducing minerals, ores, and other materials; Machines for ——. W. E. Bleloch and H. A. Stockman. E.P. 186,693, 1.7.21 and 7.2.22.

At each end of a strong rectangular frame are mounted two anvils capable of being adjusted by wedge bolts. The frame itself is supported near these ends, the bottom of the supports being designed as pivot points for four bars attached to the four pitmen operating on the anvils. Two cylinders having their axes parallel to the side of the frame are placed, one between each pair of pitmen, and are rigidly bolted to the frame. Each cylinder is provided with a hammer piston, suitably grooved to prevent leakage and retain lubricant. At either end of each cylinder is fitted an impact block, enlarged and rounded at its outer end where it strikes the pitman, but reduced at the inner end where it receives the blows of the hammer piston. A valve casing having suitably arranged ports and passages forms part of the cylinder casting. The valve controlling the admission and release of the driving fluid to the cylinders is fixed to a vertical spindle, and is given a rocking motion by an eccentric mounted on a belt-driven horizontal shaft carried on the frame of the machine. The upper ends of the pitmen at the ends of each cylinder are connected together by a rod provided with a resilient coupling, which absorbs shock or stress between the pitmen during the operation of the machine and also permits of adjustments.—S. G. U.

Pulverising apparatus. Pulverising material. R. E. H. Pomeroy. U.S.P. 1,431,251—2, 10.10.22. Appl., (a) 19.11.21, and (b) 16.1.22.

(a) A perforated rotating shell is partly filled with balls. An exhaust fan maintains a current of air through the shell, the air entering and leaving through the peripheral perforations. (b) Sets of the apparatus described in (a) are arranged in series, the air passing from one mill to the next.—T. A. S.

Fire-extinguishing liquid and method of using same. S. H. Hamilton. U.S.P. 1,431,789, 10.10.22. Appl., 1.9.21.

A liquid containing a soluble silicate and a frothing material is injected below the surface of the burning liquid. An inert gas under pressure causes the quenching liquid to rise to the surface of the burning liquid and there form an incombustible foam.—S. G. U.

Drying materials carrying a volatile inflammable solvent; Apparatus for —— and for recovering such solvent. Dunlop Rubber Co., Ltd. From W. K. Lewis and W. Green. E.P. 181,100, 4.3.21.

See U.S.P. 1,371,914 of 1921; J., 1921, 289 a.

Centrifugal separators. S. H. Hall. E.P. 183,133, 12.7.22. Conv., 15.7.21.

Rotary dryers, kilns, furnaces, retorts, and the like; Discharging or charging devices for ——. F. D. Marshall. E.P. 186,974, 13.6.21.

Mixing and other purposes; Apparatus for regulating the feed of finely divided substances for ——. E. Whitehead. E.P. 187,029, 13.7.21.

Separating fine material; [Pneumatic] method of and apparatus for ——. G. Roth. E.P. 187,381, 15.8.21.

Fire - extinguishing materials. G.P. 358,572. *See* XII.

Optical pyrometer. G.P. 357,975. *See* XXIII.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Coal; Classification of ——. S. W. Parr. J. Ind Eng. Chem., 1922, 14, 919—923.

A useful summary of the properties of any coal is given by the calorific value and the ratio of volatile matter to fixed carbon, if these are calculated on the pure coal substance ("unit-coal") with ash, moisture, and pyrites deducted. The formula: Heat value for "unit-coal"=

$$\frac{\text{indicated B.Th.U.} - 5000\text{S}}{1{\cdot}00 - (1{\cdot}08\ \text{ash} + 22/40\text{S})}$$

("ash" is weight of ash from 1 gram of coal; S is per cent. of sulphur)

has been confirmed by comparison of results from coals of similar origin but of different ash and sulphur contents. In this the factor 1·08 is a correction for the volatile matter driven off from the ash on ignition. 5000 S is the heat derived from combustion of sulphur, and the quantity 22/40 S includes an arbitrary correction for non-pyritic sulphur. The quantities are determined on the dried coal. Similarly the "unit fixed carbon" is given by the formula,

$$\frac{\text{fixed carbon as determined}}{1\cdot00-(1\cdot08\ \text{ash}+22/40\ \text{S})}$$

the factors requiring correction affecting only the volatile matter. The classification of coals as regards these two quantities can be conveniently shown by points on a two-dimension diagram.
—C. I.

Coke; Shatter and tumbler tests for metallurgical ——. S. P. Kinney and G. St. J. Perrot. J. Ind. Eng. Chem., 1922, 14, 926—931.

The shatter test for blast-furnace coke in which 50 lb. of the material is dropped 6 ft. on to a steel plate, and the percentage remaining on a 2-in. screen ascertained, gives results concordant to 1—3%. The sample should be composed of pieces of a standard size, and large pieces about half the width of the oven are suggested. More reliable results are given by using four screens of dimensions 2 in. down to ½ in. The tumbler test, in which the sample is placed in a revolving drum and rotated a given number of times, was designed to measure the resistance of coke to abrasion in passing down the blast furnace. This it fails to do, as the proportion of the coke remaining on a ¼-in. screen is largely determined by the size of the pieces in the tumbler after a few rotations, *i.e.*, their resistance to impact. If small coke (pieces 0·25—0·75 in.) be used different cokes give very similar results, and this test appears to be of no value.—C. I.

Woods; Calorific values of American ——. S. W. Parr and C. N. Davidson. J. Ind. Eng. Chem., 1922, 14, 935—936.

Samples of wood can be dried in air at 105° C. without appreciable loss of constituents other than water, the weights being constant after 3 hrs. Samples of dried, well-seasoned woods contained 8·8—10·7% of moisture as determined by this method, and the calorific values of the dried samples ranged from 8448 B.Th.U. (hickory) to 8836 B.Th.U. (pine).—C. I.

Acetylene and ammonia; Formation of —— *during incomplete combustion.* K. A. Hofmann and E. Will. Ber., 1922, 55, 3228—3233.

The gaseous products of an inverted air flame burning in the vapours of various organic substances have been investigated by means of an apparatus in which the air supply is so adjusted that the flame just burns continuously. The following quantities of acetylene (in grams) are obtained by the decomposition of 100 g. of the organic compound: benzene, 5; phenol, 4·4; aniline, 2·5; diphenylamine, 2·7; carbazole, 2·4; pyridine, 1·7; anthracene, 1·6; anthracene residues, 0·24; coal tar, 4; middle oil from Rositz lignite tar, 1; benzoquinone, 1; hexane, 2. The formation of acetylene is partly due to thermal action, but oxidative degradation also plays a part, as is proved by the production of the gas from hexane. Hydrocyanic acid is also present in the gases (100 g. of aniline, carbazole, diphenylamine, and pyridine yield respectively up to 3, 1·5, 1·5 g., and a trace of hydrocyanic acid). Ammonia is formed to a slight extent during the combustion of air charged with a number of catalysts in hydrogen, coal gas, or benzene vapour. Hydrogen arsenide, chromyl chloride, and silicon tetrachloride impede its production, which is facilitated by osmium tetroxide and the osmium formed therefrom and, in particular, by nickel carbonyl. The action of the carbonyl (from which metallic nickel is produced) appears to indicate that the effect is due to catalytic hydrogenation of the nitrogen and not to an influence of the flame ions. The carbon liberated from benzene or coal gas favours the production of ammonia, possibly owing to the intermediate formation of hydrogen cyanide. The yields of ammonia are not improved noticeably by bringing volatile salts, such as sodium or lithium carbonates, into the flame, by spreading the flame over a porous clay surface impregnated with various salts, or by placing an inverted mantle over the orifice of the burner.—H. W.

Sulphur; Recovery of —— *from spent gas-purifying material by means of tetralin.* R. Kattwinkel. Brennstoff-Chem., 1922, 3, 310—311.

Many solvents which have been proposed from time to time for the recovery of sulphur from spent oxide either have been too dear or have given a dirty sulphur due to their solvent action on tarry substances. Tetralin (tetrahydronaphthalene), b.p. 203°—205° C., flash point 79° C., dissolves 3% of its weight of sulphur at normal temperatures and 40% at 100° C. On this account, by careful cooling, the sulphur can be produced in the form of fine crystals, all tarry matter being left in the mother liquor. The sulphur recovered is clear yellow and crystalline, burning without residue, and melting in an open tube at 119° C. After extraction, the mass is treated with hot air in order to vaporise any tetralin, and is then ready for further use.—A. G.

Petroleum oils; Sulphur compounds and oxidation of ——. C. E. Waters. J. Ind. Eng. Chem., 1922, 14, 725—727.

In a carbonisation test oils were heated to 250° C. in contact with air for 2½ hrs., diluted with petroleum ether, and the precipitate filtered off and weighed. Oils of low sulphur content had usually low carbonisation values and *vice versâ*. Sulphur compounds are contributory to rapid oxidation. A considerable part of the sulphur is found in the asphaltic matter precipitated by the addition of petroleum ether to the oxidised oil. A steam turbine sludge was found to contain 0·33% of sulphur, or 0·65% on an oil-free basis. The oil-free deposit from a transformer contained 0·57% of sulphur. Oil-free samples of carbon from an internal-combustion engine contained 0·52% to 3·08% of sulphur. The carbon residue from a coke test contained a higher percentage of sulphur than the unheated oil. Precipitates from oils exposed for 100 hrs. to sunlight and air contained considerable percentages of sulphur, roughly proportional to the sulphur content of the original oil.—H. M.

Petroleum [and other] oils; Determination of absolute viscosity of ——. W. H. Fulweiler and C. W. Jordan. J. Ind. Eng. Chem., 1922, 14, 723—724.

Petroleum, animal and vegetable oils show changes in viscosity after standing in glass viscosimeters for 24 hrs., but further standing for several weeks does not effect any considerable further change. Experiments were made on viscosimeters of the Bingham and Green type, in one of which the capillary was 24 cm. long and 0·416 mm. in diam., and in another 10 cm. long and 0·918 mm. in diam. Temperatures constant within 0·005° were obtained. A highly refined white oil showed a decrease in viscosity of 0·54% after standing for 24 hrs., and after two months, a decrease of 0·43%. A reddish filtered petroleum oil showed an increase of 0·42% in 24 hrs., and the same increase after standing for 5 weeks. A sample of an unfiltered oil exposed to light showed an increase of 1% over a similar sample kept in the dark. Castor oil showed an increase of 0·33% after standing for 24 hrs., lard oil a decrease of 0·3%.—H. M.

Viscosity of oils; Change in —— with the temperature. W. H. Herschel. J. Ind. Eng. Chem., 1922, 14, 715—723.

For petroleum products with a viscosity less than that of water, fluidity $=1/\mu=A+Bt$ (*cf.* Dean and Lane, J., 1921, 726 A). This equation indicates a straight line relation. The fluidity-temperature graphs for some of the aliphatic hydrocarbons and other very fluid liquids have a curvature which decreases as the viscosity decreases. The straight line graph are more convenient for extrapolation. Fluidity-temperature equations are applicable to definite chemical compounds of low viscosity. There is considerable doubt as to what form of equation best applies to oils of high viscosity. Slotte's formula (Beibl. Ann. Physik., 1892, 16, 182), if it be assumed that the temperature coefficient is small, may be simplified to $\mu=A/(1+at+bt^2)$. The logarithmic viscosity-temperature diagram, using Fahrenheit degrees, gives practically straight-line curves for oils of medium viscosity, and these curves meet approximately at a point. In such a diagram for naphthene base oils most of the graphs are fairly straight, with the exception of those for fuel oils from Mexico and Persia, the former showing marked viscosity hysteresis, a phenomenon characteristic of colloids, the presence of which is probably the cause of the curvature of graphs for fuel oils. Most mineral oils, especially refined lubricating oils, show approximately straight line graphs. Narrowness of cut does not influence the slope of the graphs. Graphs of fatty oils are generally more curved but less steep than those of mineral oils. The viscosities of different samples of castor oil and rape-seed oil vary considerably.—H. M.

Lubrication; Mechanism of ——. Methods of measuring the property of oiliness. R. E. Wilson and D. P. Barnard. J. Ind. Eng. Chem., 1922, 14, 682—695.

The coefficient of friction, f, of a journal bearing is a function of at least nine variables, and can only be a function of the combination of these variables in such forms that all dimensions are cancelled out. Therefore the following formula may be used: $f=\phi\ (zn/p\times c/d\times l/d\times S\times M\times O)$, where z is the viscosity of the lubricant, n the revolutions per minute, p the pressure on bearing, c diametrical clearance on bearing, d diameter of journal, l length of bearing, S surface condition of bearing, M method of oiling, and O the "oiliness" factor of the lubricant. The first factor, zn/p, includes the only three important variables involved in making tests on a given bearing under varying conditions. In curves obtained by plotting observed values of f against zn/p for two different bearings there can be distinguished a region of perfect fluid film lubrication, in which the friction coefficient is roughly proportional to zn/p; a critical point of minimum friction where the speed or viscosity becomes so low, or the pressure so high, that the fluid film begins to rupture; and a region of partial lubrication in which there is increasing friction as zn/p decreases below its critical value. The safe average operating value of zn/p should be obtained by multiplying its value at the critical point by a factor of safety of about 5. In the region of fluid film lubrication f is a function of zn/p; the oiliness of the lubricant and the nature of the bearing metal have no effect, nor has the method of oiling, so long as the bearing is filled. In the region of partial lubrication the oiliness of the lubricant is more important than its viscosity, the nature of the metal plays an important part, and f is not necessarily a function of zn/p. The "oiliness" of a lubricant is the property which causes one fluid to give lower coefficients of friction (generally at slow speeds or high loads) than another fluid of the same viscosity. The property of oiliness plays no part in perfect fluid film lubrication, but becomes important in the cases of starting and stopping, imperfect supply of oil, reciprocating motion, and some irregular conditions. The condition of oiliness lowers the critical value and enables a lower factor of safety to be employed. A friction machine of the Deeley type was used to investigate the coefficient of friction. Using surfaces of glass it was found that oils containing 5% of neutral lard oil and 1% of stearic acid gave much lower values for the coefficient than did straight mineral oil. Using cast iron and steel surfaces, the presence of 0·5% of stearic acid lowered the coefficient to less than one half. Attempts were made to determine the static coefficient between perfectly smooth, flat surfaces. Experiments were made on the interfacial tension of liquids and metal surfaces. The lowering of interfacial energy is a measure of the tendency of some constituent to concentrate at the metal surface; a lowering of the friction coefficient depends on the nature and structure of the adsorbed film. Measurements of the electrical resistance of adsorbed films were made, and a study was made of the clogging of capillaries, of the adsorption of stearic acid by iron reduced in hydrogen, and of cutting lubricants.—H. M.

Lubricating oils; Bearing friction and friction experiments with ——. Duffing. Z. angew. Chem., 1922, 35, 605—607.

A certain force, K, is required to produce deformation of the ultimate particles of a lubricant in flowing motion, and $K=\mu dV/d_u$, where K is the force per unit of surface in dynes/cm.^{2}, V is the velocity in cm./sec., d_n the distance between the nearest layers, and μ units of absolute viscosity. In cases of laminar flow the following formulæ accord with the results of practice: $\delta p/\delta x=\mu\Delta u$; $\delta p/\delta y=\mu\Delta v$; $\delta u/\delta x \mp \delta v/\delta y=0$. In these formulæ $\Delta=\delta^2/\delta x^2+\delta^2/\delta y^2$ is equivalent to Laplace's operator. These formulæ may be made easier to deal with by the introduction of the function of flow, Ψ, but are still subject to difficulties caused by the edge conditions. It has been supposed that the lubricant is between two flat surfaces, under constant pressure, and that the surfaces move with a constant velocity. The conditions are much more complicated in the case of a bearing, in which the viscosity, μ, can be calculated from the moment of friction by the formula $Mr=4\pi\mu\omega R_1^2R_2^2/(R_1^2-R_2^2)$. The case is, however, quite different if the journal lies eccentric to the bearing. This produces a great increase in pressure, which may reach 60—70 atm. A machine has been constructed for the measurement of friction under such conditions; the bearing is suspended in a stirrup, and any desired pressure may be put upon it. The velocity may be varied from 3000 to 16,000 revs. per min. and the pressure may be raised to 8000 kg.—H. M.

Patents.

Peat; Apparatus for dewatering and compressing ——. C. W. G. Clewlow. E.P. 186,690, 1.7.21.

The apparatus deals with peat which has received preliminary treatment, *e.g.*, by heat and pressure, in order to render the moisture mechanically separable. A conical feed hopper is connected at its base to a chamber containing a perforated cage, so that an annular space is left for drainage. The cage is removable and is in the form of an inverted truncated cone. From this basket the material falls to a compacting, compressing and delivering device consisting of a screw conveyor working in a perforated liner, leaving an annular drainage space in the conveyor chamber, and a ram extrusion press fed by the screw conveyor. The shaft of the conveyor is hollow and a steam injector supplies petroleum or hot tar through the hollow shaft and discharges the hot oil through a hole in the side of the shaft into the peat passing through the conveyor chamber.—A. G.

Coal; Process of recovering —— held in suspension from coal-bearing water and streams. C. E. Holland. U.S.P. 1,397,735, 22.11.21. Appl., 13.11.20.

In a process for the treatment of water from streams draining coal-mining districts, the coal and organic matter in the liquid are coagulated and precipitated by passing an electric current through the liquid as it flows continuously through a tank, and the coagulum and precipitate separated from the liquid by sedimentation and filter-pressing. —H. Hg.

Coking of coal. S. R. Illingworth. E.P. 186,384, 26.5.21. Addn. to 164,104.

The coking process described in the earlier patent (J., 1921, 501 A) may be carried out under reduced pressure, this being particularly advantageous when the higher temperatures are employed. The vacuum used would depend upon circumstances, but at temperatures above 450° C. a vacuum of at least 20 inches of mercury would be necessary, and above 600° C. endeavours would be made to attain 28 inches.—W. P.

Coke oven. A. Roberts, Assr. to Chicago Trust Co. U.S.P. 1,430,588, 3.10.22. Appl., 8.3.20.

The heating wall has a number of vertical flame flues communicating with a transfer flue, the latter being reinforced by tie blocks which allow of free passage of the gas.—W. P.

Retorts [; Rotary ——] for treatment of carbonaceous or other material. F. D. Marshall. E.P. 186,375, 24.5.21.*

In rotary retorts which are heated by the passage of hot gases through their interior, baffles or internal shelves, G (see fig.), are provided, having one end attached to the inner face of the retort chamber, the other end projecting towards the interior. The shelves are bent or corrugated so as to form pockets for collecting the material from the bottom of the retort as the latter revolves, and showering it upon the surface of the shelf immediately in advance. To stiffen the shelves the inner ends may be connected together or fixed to a circular plate. The shelves may also be perforated or constructed as grids, and instead of being arranged in lines parallel to the sides of the retort, they may follow the curvature of the sides, so as to form portions of a spiral, thus imparting a swirling motion to the gases. Propellers or the like, H, I, may also be arranged between the sets of shelves and at the inlet end of the retort to break up and to impart a whirling motion to the heating gases, as shown by the arrows.—A. R. M.

FIG.1.

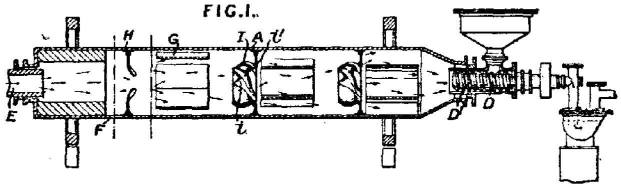

FIG.3.

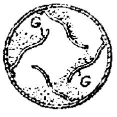

Coal or the like; Manufacture of liquid or soluble organic compounds from ——. F. Bergius. G.P. (A) 303,272, 25.12.14, (B) 307,671, 18.7.15.

About 88% of the constituents of coal are converted into liquid or soluble products by heating the coal with hydrogen under pressure in the presence of (A) a liquid dispersoid which is capable of restricting the reaction, *e.g.*, high-boiling mineral oil or tar, or their high-boiling distillates or distillation residues, or (B) a liquid product which has been obtained by hydrogenating coal, and is capable of further hydrogenation at the temperature of the reaction. —L. A. C.

Burning hydrocarbon oils; Method and apparatus for ——. C. E. Chapman and J. Goodfellow. E.P. 186,446, 6.7.21.*

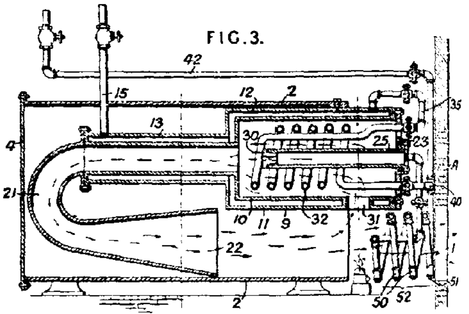

FIG.3.

Complete combustion of heavy hydrocarbon oil is attained by atomising it with superheated steam into a retort-like device, 10, provided with a cooling jacket, 12. The retort is fitted with a discharge horn, 21, having a bell mouth from which the flame enters the furnace, first impinging on the superheater, 52, supplying steam to the atomiser, 30. Part of the products of combustion is drawn in through the opening, 31, and circulated through the retort along with the incoming atomised oil. The retort and horn are lined with refractory material. —T. A. S.

Gas scrubber with rotating drum. Berlin-Anhaltische Maschinenbau A.-G. G.P. 356,434, 23.5.20.

A rotating drum containing liquor for scrubbing the gas is provided with an annular partition constructed of two perforated cylinders, containing filling material, and with one or more baffles, parallel to the ends of the drum, with openings alternately in the middle and at the circumference for the passage of the gas.—L. A. C.

Tar and the like; Process for increasing the yield of —— in purifying hot producer gas. Façoneisen-Walzwerk L. Mannstaedt und Co. A.-G., and H. Bansen. G.P. 358,592, 12.5.18.

Tar or an emulsion of tar-oil and water produced by injecting water into hot producer gas, or by partially cooling producer gas having a high water content, is again brought in contact with the hot gas,

whereby water is evaporated from the tar or emulsion, and condensed on further cooling the gas.
—L. A. C.

Desulphurising petroleum and similar oil. W. R. Walkey and A. F. Bargate. E.P. 186,738, 18.7.21.

The oil to be desulphurised is vaporised in the presence of steam and a gaseous dissociating agent, *e.g.*, chlorine or sulphur dioxide, to decompose the hydrogen sulphide formed. The reaction is rendered more effective by passing the gaseous products through a chamber, packed with porous material and surrounded with an electric coil to produce a magnetic field. A convenient chamber can be made out of 5 feet of 6" pipe round which is coiled 3¼ miles of copper wire of $\frac{1}{32}$" diameter, carrying a current of 20 ampères.—T. A. S.

Hydrocarbons; Process and apparatus for treating ——. W. Münder, Assr. to The Chemical Foundation, Inc. U.S.P. 1,431,246, 10.10.22. Appl., 31.12.15.

Light hydrocarbons free from asphalt and sulphur are produced by subjecting heavy hydrocarbons to distillation under ordinary pressure. The distillate is then heated under pressure, with continuous distillation, in an autoclave.—T. A. S.

Hydrocarbons; Process and apparatus for treating —— to produce those of lower boiling point. J. C. Black. U.S.P. 1,431,772, 10.10.22. Appl., 15.8.21.

Oil is cracked by passing it through a coil, heated to cracking temperature, and maintaining it at this temperature for some time in a "digester" of arger cross-sectional area than the cracking coil. The oil is then passed through chambers where the pressure is successively diminished to cause the vaporisation of the various fractions.—T. A. S.

Petroleum refining; Recovery of by-products of ——. C. I. Robinson, Assr. to Standard Oil Co. U.S.P. 1,431,259, 10.10.22. Appl., 3.10.19.

The unsaturated portions of light hydrocarbons produced in the heat treatment of petroleum are recovered by treating the oils with 90% sulphuric acid at 55°—75° F. (13°—24° C.). The resulting sludge is separated and diluted, whereby the oily constituents are separated. The aqueous acid is distilled, the distillate consisting of an oily layer and aqueous alcohols.—T. A. S.

Hydrocarbon oils; Treating [refining] ——. Deutsche Erdöl A.-G., Assees. of F. Schick. G.P. 357,768, 19.3.21.

Hydrocarbon oils are treated with alcohols to which an appropriate small amount of water, acids, or alkalis is added, so as to cause the separation of a layer containing the colouring, odorous, resinous, and asphaltic matter from the hydrocarbon oils, which are subsequently treated with alcoholic solutions of acids and alkalis. A solution of hydrochloric acid in ethyl alcohol, or sulphuric acid in amyl alcohol, alcoholates, or an alcoholic solution of pyridine may be so employed.—J. S. G. T.

Coal; Process for reclaiming and recovery of —— from water or other liquids. C. E. Holland. E.P. 171,670, 7.9.21. Conv., 13.11.20.

See U.S.P. 1,397,735 of 1921; preceding.

Fuel feeding and drying apparatus. W. R. Wood. U.S.P. 1,432,509, 17.10.22. Appl., 16.12.19.

See E.P. 124,314 of 1918; J., 1919, 312 A.

Carbonaceous material; Apparatus and process for treating —— for the recovery of the volatile hydrocarbon constituents thereof. C. C. Bussey, Assr. to S. E. Darby. U.S.P. 1,432,275–6, 17.10.22. Appl., 10.4.18.

Lamp wicks; Process for treating ——. J. Feeney. E.P. 173,208, 6.8.21. Conv., 18.12.20.

Lamp wicks are immersed in milk of lime of sp. gr. 1·100, and the solution boiled until its sp. gr. becomes 1·150. The wicks are then removed and dried. Wicks so prepared burn without smoking and are more durable.—J. S. G. T.

Incandescence mantles and process of manufacture. Aktiebolaget Keros. G.P. 358,514, 18.12.21. Conv., 15.1.21.

Fibres impregnated with solutions of salts of the rare earths are assembled parallel to one another and after the addition of an agglutinant are subjected to pressure. The resulting fibres, either prior to or subsequent to ignition, are woven into the form of mantles, so that their longer axes are essentially normal to the contour of the luminous surface of the mantle. Mantles so prepared possess increased rigidity and elasticity, and a considerably higher lighting efficiency.—J. S. G. T.

III.—TAR AND TAR PRODUCTS.

Phenols of coke-oven tar and low-temperature tar; Conversion of —— into benzene in an experimental installation. F. Fischer, H. Schrader, and K. Zerbe. Brennstoff-Chem., 1922, 3, 305—307.

The semi-industrial plant previously described (J., 1922, 891 A) was used in order to investigate whether results obtained on such a scale were comparable with those obtained in a laboratory apparatus, in which a 90% yield of benzene was obtained by reduction of phenols with hydrogen in a tinned iron tube. The quantity of phenol put through the plant varied from 220 to 12,300 g. per hr., and the velocity of the hydrogen varied from 8 to 99 l. per hr. correspondingly. The crude benzol obtained, of b.p. 80°—100° C., varied from 50·9% of the theoretical yield, using 815 g. of cresol mixture per hr., to 81·7% with 3100 g. per hr. Coal gas was used in one experiment in place of hydrogen, the yield obtained being 73·0% of the theoretical, but there was a slight separation of carbon.—A. G.

Benzene from lignite. F. Fischer and H. Schrader. Brennstoff-Chem., 1922, 3, 307—310.

The authors, continuing the work described in the preceding abstract, find that almost 50% of the weight of phenols from lignite tars can be reduced to benzol by means of hydrogen. The benzol is mixed with other substances boiling at temperatures up to 180° C. The calorific value of benzene is about 10,000 cals./g., whilst that of phenol is only 7800 cals./g., so that for equivalent calorific values 78 g. of benzol corresponds to 100 g. of phenol. The phenols are derived from the humus portion of the coal, and whilst in gasworks benzene is formed direct in the retorts, in low-temperature operations it must be produced by reduction of the phenols occurring in the tar.—A. G.

Creosote oils; Coke residue test for ——. C. S. Reeve and F. W. Yeager. J. Ind. Eng. Chem., 1922, 14, 966—967.

Wide variations in results are obtained when the coke residue of creosote oil is determined by coking in a glass bulb. This is due to the tendency of the glass to fuse at the full temperature required for coking. Very concordant results, slightly lower than the average results with glass bulbs, are obtained by distilling to 355° C. in a retort and coking the residue in a platinum crucible.—C. I.

Products of coal carbonisation [xylol]; Decomposition processes applicable to certain ——. M. J. Bradley and S. W. Parr. Chem. and Met. Eng., 1922, 27, 737—744.

Tar oils consisting mainly of xylol could be obtained in large quantities by the low-temperature carbonisation of coal if the demand for them justified it. In order to find further uses a research was carried out on the decomposition products of xylol in an electric furnace at temperatures between 250° and 900° C. and in presence of different gases and contact surfaces. Amongst the results were the following. In an atmosphere of hydrogen and methane the decomposition products are benzene and methane in theoretical proportions. In presence of ethylene the main products are high-boiling compounds, chiefly solid. Iron or metallic oxide surfaces cause a complete decomposition into carbon and gaseous products. Surfaces of carbon, pumice, etc. favour the production of unsaturated high-boiling compounds. Carbon dioxide and steam render liquid hydrocarbons more stable. The effect of increased pressure depends entirely on the gas present. Amongst the products identified were *n*-hexane, cyclohexane, diphenyl, ditolyl, stilbene, phenanthrene, naphthalene, anthracene, methyl derivatives of the two last, pyrene, and chrysene.
—C. I.

Pernitric acid as an analytical reagent. [*Detection of aniline, benzene, hydrogen peroxide, and nitrites.*] I. Trifonow. Z. anorg. Chem., 1922, 124, 136—139.

Pernitric acid reacts with aniline, yielding an intensely yellow product. The per-acid is formed by the action of hydrogen peroxide on an acidified solution of a nitrite (*cf.* page 936 A). The above reaction with aniline can therefore be employed for the detection of hydrogen peroxide or nitrite. Benzene gives with pernitric acid a yellow colour which changes into dark red on the addition of alkali. Toluene and xylene gave a fainter yellow colour, which, however, does not change on the addition of alkali. Thus benzene can be detected in the presence of toluene, xylene, and the aliphatic hydrocarbons; the aliphatic members are not coloured. Similarly benzene can be detected in methylated spirits.—W. T.

Anthraquinone; Quantitative determination of ——. O. A. Nelson and C. E. Senseman. J. Ind. Eng. Chem., 1922, 14, 956—957.

The method for estimating anthraquinone described by Lewis (J., 1918, 459 A) has been modified so that a determination can be completed in about ½ hour. To about 0·5 g. of the sample of anthraquinone thoroughly ground with 3—4 g. of zinc dust, is added 100 c.c. of a boiling 5% solution of caustic soda. After standing for 5 mins., the red product is filtered into a suction flask, through a layer of asbestos fitted within a filter consisting of a glass tube, 24 cm. long and 3·5 cm. diam. and suitably tapered at one end. This filtering tube contains a mechanical stirrer and is heated electrically to 90°—95° C. The residue is washed with hot caustic soda solution until it contains no anthraquinone. The red solution of oxanthranol is titrated in the suction flask with a standardised solution of potassium permanganate (3·8 g. per l.) until it is colourless. Beyond this end point, the addition of permanganate produces a dark green colour, or bluish-green when phenanthraquinone is also present. The potassium permanganate solution is standardised by means of pure anthraquinone under the same conditions, and provided that oxidation by air is prevented, the method gives accurate results even in instances where the anthraquinone contains phenanthraquinone, anthracene, phenanthrene, phthalic anhydride, phthalic acid, or other oxidation products of anthracene and phenanthrene.
—A. J. H.

β-Naphthylamine; Analysis of ——. H. R. Lee and D. O. Jones. J. Ind. Eng. Chem., 1922, 14, 961—963.

Methods for the estimation of β-naphthylamine in the presence of β-naphthol, ββ-dinaphthylamine, and α-naphthylamine have been tested by means of specially purified samples of these substances. In the usual direct nitrite titration method, high results are obtained when β-naphthol is present, since this is converted into nitroso-β-naphthol. Direct titration with $N/10$ sodium nitrite at 20° C. gives results higher than theory even when β-naphthol is absent, and it is better to use $N/2$ nitrite at 0°—5° C. β-Naphthol-1-sulphonic acid is not affected by nitrous acid and on this fact is based the following accurate method: 0·65 g. of the sample of β-naphthylamine is sulphonated, initially at 0°—5° C. and finally at 15° C. when necessary, with 20 c.c. of 25% oleum. The product is diluted with ice and boiled to remove sulphur dioxide, then diluted to 200 c.c., cooled to 20° C., and, after the addition of 15 c.c. of concentrated hydrochloric acid, is titrated with $N/10$ sodium nitrite, the end point being reached when a distinct blue colour develops with starch-iodide 5 mins. after the last addition of nitrite. If 3·5 g. of the sample is used, titration is carried out with $N/2$ nitrite at 0°—5° C. If in this method an amine content of 96% and a m.p. of 109° C. or higher is obtained, the absence of any appreciable amount of impurities is assured. The following method is suitable for the accurate determination of both β-naphthylamine and β-naphthol. Dry hydrogen chloride is passed through a solution of 3·5 g. of the sample in 300 c.c. of dry benzene for 1—2 hrs., the precipitated β-naphthylamine hydrochloride is filtered off, washed with dry benzene saturated with hydrogen chloride, and dried at 60° C. *in vacuo*. It is then dissolved in not more than 200 c.c. of water, and after the addition of 25 c.c. of 20% hydrochloric acid, the β-naphthylamine is determined by titrating with *N*/2 sodium nitrite at 0°—5° C. The benzene filtrate is evaporated to dryness (loss of β-naphthol by sublimation must be avoided), the residue dissolved in 200 c.c. of 1% caustic soda, and β-naphthol determined, after acidifying with hydrochloric acid and adding an excess of sodium bicarbonate, by titrating with *N*/2 diazotised *p*-nitraniline solution. A modified Kjeldahl-Gunning method is also described. Acid-insoluble impurities are estimated by dissolving 5 g. of the sample in 150 c.c. of boiling 1·5% hydrochloric acid, filtering the solution through a Gooch crucible, washing the residue with hot water, and drying to constant weight at 100° C. At least 10% of the β-naphthol present passes into the filtrate, whereas only 0·1—0·2% of ββ-dinaphthylamine is soluble. Hence the latter can be isolated from the residue by solvent extraction and then weighed or analysed for nitrogen. Melting point curves for the binary systems, β-naphthylamine+β-naphthol, β-naphthylamine+ββ-dinaphthylamine, and β-naphthylamine+α-naphthylamine are given, and by means of the last-named the amount of α-naphthylamine in β-naphthylamine not containing large amounts of β-naphthol and ββ-dinaphthylamine may be estimated. The following specifications are suggested for technical β-naphthylamine: m.p. not below 109·0° C. (corr.); content of β-naphthylamine not less than 96·0%, β-naphthol, insoluble matter, and moisture not more than 3·0%, 0·5%, and 0·5% respectively. (*Cf.* J.C.S., Dec.)—A. J. H.

Aromatic hydrocarbons; Process of producing ——. A. S. Ramage, Assr. to Bostaph Engineering Corp. U.S.P. 1,430,585, 3.10.22. Appl., 24.6.18. Renewed 23.2.22.

Phenols are converted into aromatic hydrocarbons by treating with hydrogen at about 700° C. in the presence of a catalyst consisting of a lower oxide of iron.—W. P.

Paraffin-wax; Production of —— [*from lignite tars, producer gas tars, etc.*]. T. Helvey. G.P. 357,303, 2.7.21.

Paraffins of various degrees of purity, *e.g.*, ceresin, stearin, montan wax, or oils containing paraffin wax, are added to the tar heated to about 80° C., and the whole stirred. The mixture is then treated with water, salt solutions, lyes, or acids, the layer richer in paraffin separated, and the paraffin-wax recovered therefrom.—J. S. G. T.

1.4-*Naphtholsulphonic acid*; *Manufacture of* ——. British Dyestuffs Corp., Ltd., J. Baddiley, J. B. Payman, and E. G. Bainbridge. E.P. 186,515, 10.9.21.

1.4-Naphtholsulphonic acid is obtained in good yield and quality by the action of chlorosulphonic acid on α-naphthol in presence of a suitable solvent, preferably tetrachloroethane. *Example.* 144 pts. of α-naphthol is suspended in 600 pts. of tetrachloroethane, and 127 pts. of distilled chlorosulphonic acid is added, the temperature being maintained below 80° C. The mixture is then heated at 50° C. for 24 hrs. After dilution with water, and separation of the tetrachloroethane, the liquor is neutralised with either lime or sodium carbonate. The isomeric acids present should not amount to more than 1—2%, and if desired they can be removed by adding barium chloride solution until a precipitate ceases to form.—G. F. M.

Dec.)—A. J. H.

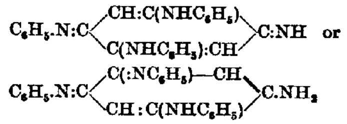
Pitch; Treating ——. F. J. Commin. U.S.P. 1,432,742, 24.10.22. Appl., 27.12.20.

See E.P. 162,727 of 1920; J., 1921, 462 A.

IV.—COLOURING MATTERS AND DYES.

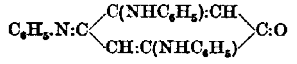
Aniline; Oxidation of ——. *Amine oxidation. VII.* S. Goldschmidt and B. Wurzschmitt. Ber., 1922, 55, 3220—3227.

Benzoquinonephenyldi-imine, $N(C_6H_5){:}C_6H_4{:}NH$ is polymerised by glacial acetic acid or a small quantity of hydrochloric acid in the presence of ether almost quantitatively to the trimeride, $N(C_6H_5){:}C_6H_2(NH.C_6H_4.NH.C_6H_5)_2{:}NH$ (*cf.* Willstätter and Kubli, J., 1909, 1244). It depends essentially on the nature and quantity of the added acid (and therefore on the hydrogen ion concentration) whether the di-imine is polymerised to Emeraldine or to Willstätter's compound. The substance,



which has been isolated by oxidising aniline salts with lead peroxide by Börnstein (*cf.* Majima and Aoki, J., 1911, 1369) is obtained under comparable conditions when benzoquinonephenyldi-imine is condensed with aniline. Azophenine,

obtained according to Börnstein (J., 1901, 701) by the further oxidation of aniline, is produced when aniline is mixed with dianilinobenzoquinonephenyldi-imine in ethereal solution in the presence of a little glacial acetic acid. Dianilinobenzoquinoneanil,



formed by the oxidation of aniline in acid solution by hydrogen peroxide, owes its production to the hydrolysis of benzoquinonephenyldi-imine to ammonia and benzoquinonephenylimine,

$$C_6H_5.N{:}C_6H_4{:}O$$

and condensation of the latter with aniline. The complex products of the oxidation of aniline appear therefore to be largely due to the intermediate formation of benzoquinonephenyldi-imine and its subsequent decomposition in various directions. (*Cf.* J.C.S., Dec.)—H. W.

H-acid and its intermediates obtained from naphthalene-2.7-disulphonic acid; Method for identifying ——. D. F. J. Lynch. J. Ind. Eng. Chem., 1922, 14, 964—965.

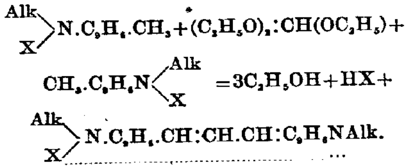
A method for identifying 1.8-dinitro-3.6-naphthalenedisulphonic, 1.8-diamino-3.6-naphthalenedisulphonic, 1.8-aminonaphthol-3.6-disulphonic (H-acid), and 1.8-dihydroxynaphthalene-3.6-disulphonic (chromotropic) acids in the presence of each other by means of their reactions with solutions containing benzidine hydrochloride, 2-cymidine sulphate, α-naphthylamine-hydrochloric acid, pseudocumidine-hydrochloric acid, tolidine-hydrochloric acid, *p*-nitrotoluidine-hydrochloric acid, cobalt chloride, and zinc sulphate is developed. Except those in which cobalt chloride and zinc sulphate are used (neutral solution is then necessary), the tests are carried out with 3—5 c.c. of 5—10% hydrochloric acid containing not more than 0·1 mol. of the sulphonic acid per l. The physical properties of several organic salts of these four sulphonic acids are described. (*Cf.* J.C.S., Dec.)—A. J. H.

1-*Hydroxylaminoanthraquinone and some of its derivatives.* W. H. Beisler and L. W. Jones. J. Amer. Chem. Soc., 1922, 44, 2296—2306.

1-Nitroanthraquinone is best prepared by warming anthraquinone with fuming nitric acid (sp. gr. 1·60), and crystallising the crude product successively from glacial acetic acid, toluene, and acetone. It has m.p. 232·5°—233·5° C. and the amino compound obtained by reduction with potassium sulphide has m.p. 252°—253° C. When the nitro compound is reduced in pyridine solution with hydrogen sulphide it yields 1-hydroxylaminoanthraquinone, the sulphonic acid derivative of which dyes wool and silk reddish-brown without a mordant. When air is bubbled through the aqueous solution of the hydroxylamino compound 1-nitrosoanthraquinone is obtained. —W. G.

Pinacyanols; Constitution of the ——, a contribution to the chemistry of the quinocyanines. W. König. Ber., 1922, 55, 3293—3313.

The structure assigned to Pinacyanol by Mills and Hamer (J., 1921, 41 A) has been confirmed by a comparison of the absorption spectra of Pinacyanol and ψ-isocyanine and estimation of the persistence and maxima, and by the synthesis of Pinacyanols by the condensation of quinaldinium salts with ethyl orthoformate in the presence of suitable agents such as acetic anhydride or zinc chloride:



$$\overset{Alk}{\underset{X}{>}}N.C_9H_6.CH_3+(C_2H_5O)_2:CH(OC_2H_5)+CH_3.C_9H_6N\overset{Alk}{\underset{X}{<}}=3C_2H_5OH+HX+\overset{Alk}{\underset{X}{>}}N.C_9H_6.CH:CH.CH:C_9H_6NAlk.$$

Since the constitution of the cyanines has been largely elucidated, it appears desirable to delete the common names of the substances (*e.g.*, cyanines, isocyanines, ψ-isocyanines, etc.) from the scientific literature and to replace them by the general term quinocyanines, by which is understood the salts of quinolyldihydroquinolylenemethanes which are not methylated at the nitrogen atom. The three classes, 2.2′, 2.4′ and 4.4′-quinocyanine salts, are thus suitably distinguished. The further derivatives are termed benzothioazolocyanines (thiocyanines) and indoleninocyanines (indocyanines). Further types are produced by the streptostatic introduction of vinylene groups between the quinoline residues and are designated mono- (di-, tri- etc.) vinylene-2.2′ or 2.4′ or 4.4′-quinocyanine salts. As examples may be quoted: dimethyl-ψ-isocyanine iodide = 1.1′-dimethyl-2.2′-quinocyanine iodide; Pinaverdol=1.6.1′-trimethyl-2.4′-quinocyanine iodide; ψ-dicyanine bromide=1.1′-diethyl-4.6.4′.6′-tetramethylstreptomonovinylene-2.2′-quinocyanine bromide; dicyanine=1.1′-diethyl-4.6.2′.6′-tetramethylstreptomonovinylene-2.4′-quinocyanine iodide. (*Cf.* J.C.S., Dec.)—H. W.

Patents.

Basic dyestuffs [triarylmethane derivatives containing a thiazole ring]; Manufacture of new —— possessing affinity for unmordanted vegetable fibre. British Dyestuffs Corp., Ltd., J. Baddiley, E. H. Rodd, and H. H. Stocks. E.P. 186,517, 14.9.21.

A new series of basic dyestuffs are obtained by condensing Michler's hydrol or its homologues with a suitable arylbenzthiazole by means of sulphuric acid and oxidising the resulting leuco compound. As instances of the benzthiazoles which can be used 1-phenyl-5-methylbenzthiazole, prepared by treating benzyl-*p*-toluidine with sulphur, and 4′-amino-1-phenyl-5-methylbenzthiazole (dehydrothiotoluidine) are mentioned. The new dyestuffs are green, and dye wool and tannin-mordanted cotton in bright shades of a fastness exceeding that of known basic greens. They have in addition the property of dyeing unmordanted cotton, giving shades of a brightness hitherto unapproached by a substantive cotton green. They are also useful in dyeing paper, yielding a clean "back-water." *Example.* 27 pts. of Michler's hydrol (tetramethyldiaminobenzhydrol) and 22·5 pts. of 1-phenyl-5-methylbenzthiazole are mixed together, charged into 250 pts. of sulphuric acid monohydrate, and heated on a water bath for 5 hrs. The mixture is then diluted, and the leuco base precipitated by neutralising with sodium hydroxide. It is collected, dissolved in hydrochloric acid, and oxidised with lead peroxide. The lead is finally removed as sulphate, and the dye precipitated by the addition of common salt.—G. F. M.

Azo-dyestuffs; Manufacture of chromium compound of ——. Soc. of Chem. Ind. in Basle, and F. Straub. E.P. 186,635, 18.3.21. Addn. to 104,04 (*cf.* U.S.P. 1,221,849; J., 1917, 542).

Azo dyestuffs capable of being chromed are treated in alkaline solution with the complex chromium compounds formed by the action of alkaline suspensions of chromium hydroxide on organic compound containing more than one hydroxyl group, *e.g.* polyhydric alcohols and phenols, tanning agent sugars, and organic by-products from the manufacture of sulphite-cellulose. For example, 20·8 pts. glycerin is added to a solution of 46·8 pts. of potassium hydroxide in an aqueous paste of chromiu hydroxide containing 14 pts. of chromic oxide, an the mixture is boiled until the chromium hydroxid has dissolved. The solution is made up to 200 pt 71·2 pts. of the dyestuff from diazotised 1-amino-hydroxynaphthalene-4-sulphonic acid and α-naphthol is added, the solution is boiled for 10 hrs. und a reflux condenser, diluted with 600 pts. of co water, and, after neutralisation of the alkali wi mineral acid, the dyestuff is salted out, filtered, a dried. The product dyes wool in an acid bath de blue shades fast to light and fulling.—L. A. C.

Safranines; Preparation of anthraquinonyl deri tives of ——. Akt.-Ges. für Anilin-Fabr., Asse of W. Herzberg and W. Bruck. G.P. 357,2 31.3.20. Addn. to 355,491 (J., 1922, 853 A).

In the process described in the chief patent, anth quinone derivatives are employed in which t primary amino group is attached to the anth quinone nucleus by means of an intermediate gro For example, 1-*p*-aminophenylaminoanthraquin is treated with dimethylisorosinduline chlor (Neutral Blue) and sodium hydroxide in the p sence of nitrobenzene at 50° C. until a test port gives a grass-green solution in concentrated s phuric acid. The crystalline product on treatm with 25% oleum yields a water-soluble sulphonic a which dyes wool indigo-blue shades from a vat. —L. A. C

Colour lakes. G.P. 358,047. *See* XIII.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Wood of eucalyptus (Eucalyptus globulus) western white pine (Pinus monticola); Anal of ——. S. A. Mahood and D. E. Cable. J. Eng. Chem., 1922, 14, 933—934.

A continuation of work previously described Schorger, J., 1917, 867 A). The solubility of n various solvents is considerably influenced by ts state of division; in these investigations all amples were reduced to sawdust which passed hrough an 80-mesh and was retained by a 100-mesh ieve. The composition of western white pine is imilar to that of longleaf pine, although the latter ields more soluble matter to cold and hot water nd alkali. Although, on destructive distillation, ucalyptus yields nearly as much acetic acid as a ardwood, the yield of acetic acid on hydrolysis is nuch less than that similarly obtained from hardwoods previously analysed (*loc. cit*). Eucalyptus esembles conifers in its low ash content. The ellulose isolated from western white pine and ucalyptus contains approximately the same mount of α-cellulose, but the remaining cellulose is lmost entirely γ-cellulose in the case of eucalyptus nd an equal mixture of β- and γ-cellulose in he case of western white pine. The lignin con-ent was determined by extracting 2 g. of the ir-dried material for 4 hrs. with a mixture of lcohol and benzene of minimum b.p., afterwards isintegrating it by treatment for 16 hrs. at room emperature with ten times its weight of 72% ulphuric acid, then boiling the product, after ilution, till its acid content was 3%, for 2 hrs. nder a reflux condenser, and filtering through a ared alundum crucible. The residue was washed ree from acid with hot water, dried at 105° C., and eighed as lignin.—A. J. H.

ood; Removal of resin from —— prior to the manufacture of cellulose. H. Wenzl. Zellstoff u. Papier, 1922, 2, 228—232.

ETHODS depending on the use of petroleum hydro-rbons in which 90% of the total resin is extracted ve been worked out, some of them depending on e use of high pressures and moderate tempera-res. Chlorinated hydrocarbons are hardly itable, but "tetralin" (tetrahydronaphthalene) pears particularly promising. The process of nson and Bennett with the use of 70% alcohol ., 1922, 380 A), is of interest as a subsidiary of e sulphite spirit scheme, since much of the quisite plant is common to both. When the e of the wood particles is reduced to 25×45 mm. e extraction of 71% of the resin content has en effected. Methods depending on the use of ulsified organic solvents have not been very ccessful in spite of the low cost, owing to the fective penetrating power of such emulsions. In e process molten resin or pitch has been employed 200° C. for the treatment of very resinous wood ste, but the residual wood is rendered useless r cellulose manufacture. A process of extraction ith dilute ammonia solution at 70° C. has given gh yields of resin, but it is necessary to extract e resin from the ammoniacal solution by means gasoline, and the double process is not onomical. Many processes are based on the use caustic soda and sodium carbonate for the traction of resin as a preliminary stage in the gestion of the wood for the manufacture of kraft llulose. By these methods, however, the chemical operties of the resin are profoundly modified. metimes very high pressures and moderate mperatures are recommended on this account; e use of reducing agents such as hydrosulphite, d of an indifferent atmosphere such as hydrogen s, have also been proposed.—J. F. B.

ugar formation in a sulphite digester. E. C. Sherrard and C. F. Suhm. J. Ind. Eng. Chem., 1922, 14, 931—932.

experimental digestions of white spruce by the itscherlich process, the total, free, and combined lphur dioxide in the liquor being 3·80%, 2·39%, d 1·41% respectively, little sugar was formed temperatures below 100° C. Sugar was most rapidly formed during the stage at which the wood chips suffered disintegration, and the total amount of sugar produced in the production of a good quality pulp was 11% on the weight of the dry wood used. During the early part of the digestion, the rate of formation of sugar closely followed the rate of removal of lignin. In a digestion in which the values for total, free, and combined sulphur dioxide were 5·60%, 4·46%, and 1·14% respectively, there was formed 16% of sugar, but the loss of cellulose was 2% greater.—A. J. H.

Cellulose [α-cellulose]; Determination of alkali-resistant ——. P. Waentig. Zellstoff u. Papier, 1922, 2, 225—228. (*Cf.* J., 1922, 408 A).

IN the standard method for the determination of resistant or α-cellulose in wood pulp the principal source of discrepancies is the re-precipitation of colloidal cellulose when the paste is diluted with water before filtration. A modified procedure is recommended as follows: 3·5 g. of the pulp is dried at 105° C., weighed, and steeped in a porcelain mortar with 50 c.c. of 17·5% sodium hydroxide solution for 45 mins. at the ordinary temperature, the mass being worked up with a pestle to a uniform paste. 50 c.c. of water is then stirred in and the paste is transferred to a Buchner funnel, 8—10 cm. in diam., covered with a fine cotton cloth filter. It is washed on the filter with 200 c.c. of 8% sodium hydroxide solution and sucked as dry as possible. The cake of cellulose is treated with 50 c.c. of 5% acetic acid, sucked dry again, transferred back to the mortar, broken up, and stirred again with a further 50 c.c. of 5% acetic acid. The cellulose is collected on the filter, washed until neutral to litmus paper, and dried at first on a clock glass, and then at 105° C. in a stoppered weighing bottle until the weight is constant. The results are expressed in terms of dry substance. This method generally yields values 2—3% lower than the older method, presumably because of the longer contact with alkali and the more complete washing out of the colloidal cellulose with the 8% caustic soda, but it is contended that the results are more uniform and are obtained under conditions corresponding more closely with those of practical mercerisation in the viscose industry.—J. F. B.

Paper; Application of direct dyes in colouring ——. W. C. Holmes. J. Ind. Eng. Chem., 1922, 14, 958—960.

EXCEPT for the production of light shades, direct dyes are particularly suitable for dyeing paper in the hollander. A direct dyestuff, absorbed as such by paper, produces deeper and brighter shades than when absorbed as a metallic lake. The formation of aluminium lakes in the hollander should especially be avoided, since for most colours, these are inferior in strength and brilliance to the corresponding calcium, barium, and even iron lakes. Where lake formation cannot be avoided, the calcium lakes should be produced by addition of calcium chloride. High temperatures are not desirable, but it is advantageous to add salt, since brighter effects are thereby obtained with a saving of dyestuff. In colouring ground wood furnishes, lake formation is desirable, since in this case a dyestuff, absorbed as such, produces shades of inferior depth and brightness than when absorbed as a metallic lake. When Pontamine Sky Blue 5BX is dyed upon bleached sulphite and ground wood furnishes, the depth of shade developed on the former is several times greater than that on the latter, although there is no material difference in the amounts of dye actually absorbed. Hence, in colouring ground wood furnishes calcium chloride should be added to the hollander before the introduction of the dyestuff. The fastness of shade, in the case of some direct dyestuffs, is improved by the addition of copper sulphate to the hollander, and this addition should be made after the colour has been allowed "to run" for a short period.—A. J. H.

Piezo-micrometer and its applications [to testing paper etc.]. J. Strachan. Proc. Tech. Sect. Papermakers' Assoc., 1922, 3, 20—32.

The author describes a device for determining the thickness of a sheet of paper submitted to a definite known pressure. The paper is placed between pressure plates between which a known pressure is produced by a lever system. A micrometer is adjusted so that a platinum needle carried on the end of the micrometer screw makes contact, without sensible mechanical pressure, with the upper of the two pressure plates. The contact is determined electrically by the closing of an electric circuit and is accurate to within 1/20,000 inch. The thickness of the sheet of paper is obtained from the micrometer reading in the usual manner. Graphs are given of the relation of the volume, V, of samples of various materials—untanned kid skin, rubber, varieties of paper—to the pressure, P. There is a time lag between the application of the pressure and the attainment of the maximum appropriate compression. Between the limits of compression, P and V are related by the equation $PV^n=constant$. Air space in paper comprises interstitial air-space and porosity air-space, the former consisting of space between the fibrous and mineral constituents of the paper, the latter consisting of the capillary pores in the material, and the author contends that the calculation of air-space by the method adopted in the "C.B.S. Units" is liable to error.—J. S. G. T.

Humidity equilibria. Wilson and Fuwa. *See* I.

Patents.

Fibrous or artificial filamentary materials; Apparatus for treating with liquids ——. F. Linnemann. E.P. 169,695, 15.9.21. Conv., 1.10.20.

Hanks of fibrous material or, *e.g.*, artificial silk, are supported on hank rods attached to a vertically reciprocating frame extending over a series of tanks containing liquor for treating the material. The movement of the frame alternately submerges the hanks and raises them out of the liquor, and, while the hanks are hanging out of the liquor, moves them along the series. The liquid may flow continuously through the tanks in the opposite direction to that of the hanks, or means may be provided for admitting a fresh supply of liquid to the tanks each time the hanks are raised.—L. A. C.

Textile fabric; Artificial —— and process for its manufacture. J. E. Brandenberger. U.S.P. 1,394,270, 18.10.21. Appl., 18.5.20.

A viscous solution such as is used for the manufacture of artificial silk is emulsified with air or other inert gas, the emulsion is allowed to stand for a time to allow large bubbles to rise and break, and is then spun into threads in the usual way. The threads thus obtained contain numerous minute bubbles and are therefore very light, opaque, and warm to the touch. By suitable regulation of the quantity of bubbles thus introduced, a material having the appearance and feel of wool can be obtained.

Vulcanised fibre; Separating chlorine compounds from ——. Elektro-Osmose A.-G. (Graf Schwerin Ges.). G.P. 357,057, 23.3.20.

Vulcanised fibre disposed between diaphragms constructed of fibrous vegetable material so arranged that the cations migrate more rapidly than the anions, is subjected to the electro-osmotic action of a continuous electric current, and is thereby dechlorinated and improved in durability and insulating properties.—L. A. C.

Cellulosic material; Manufacture of sheets of —— with a compact surface. M. Mangold. G.P. 357,098, 12.12.18. Conv., 23.10.18.

Cellulosic material which has been compressed and subsequently loosened on the surface to hinder impregnation with liquid beyond a desired depth, is converted superficially into sodium-cellulose by treatment with sodium hydroxide, and subsequently into viscose. The surface is hardened by drying, yielding material possessing properties similar to those of viscose. In the case of material prepared from wood-pulp, substances such as carbohydrates, lignin, resins, and albumins, which hinder the formation of sodium-cellulose are removed by previous treatment under pressure with sodium hydroxide in excess.—L. A. C.

Cellulosic material; Rendering —— resistant to water. F. Beck. G.P. 357,972, 14.12.19.

Cellulose precipitated by diluting solutions of it in concentrated solutions of salts, such as calcium thiocyanate, is moulded into shape, washed with water, dried, and steeped in a concentrated solution of an alkali or alkaline-earth salt, *e.g.*, calcium thiocyanate, and again washed and dried. The treatment improves the tensile strength of the material, and renders it resistant to water.—L. A. C.

Cellulose butyrate; Process of preparing ——. G. J. Esselen, jun., and H. S. Mork, Assrs. to A. D. Little, Inc. U.S.P. 1,425,581, 15.8.22. Appl., 26.7.20.

See E.P. 167,143 of 1921; J., 1922, 748 A.

Textile fibres in the loose state; Process and apparatus for dyeing and other treatment of ——. J. T., and J. Brandwood. U.S.P. 1,432,318-9, 17.10.22. Appl., 14.5.21.

See E.P. 182,575 of 1921; J., 1922, 666 A.

Bleaching agent. G.P. 357,956–7. *See* XII.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Pernitric acid; Properties and structure of ——. I. Trifonow. Z. anorg. Chem., 1922, 124, 123-135.

Pernitric acid is formed by the action of hydrogen peroxide on an acidified nitrite solution; low temperature and low concentration are not essential for its formation. Above 70° C. it decomposes rapidly. The per-acid can be estimated by the addition of potassium bromide in dilute solution, and the determination of the liberated bromine by means of potassium iodide solution. The reaction of formation is represented by the equation

$$2HNO_2+3H_2O_2+(n-1)H_2O=N_2O_6,nH_2O+3H_2O$$

and not as given by Raschig (J., 1904, 934; 1905

276) or Schmidlin and Massini (J., 1910, 693). Pernitric acid thus receives the formula

$NO_2.O.O.NO_2,nH_2O$.

The reactions of pernitric acid with some organic compounds are given (*cf.* p. 932 A).—W. T.

Phosphoric acid, sodium phosphate, and pyrophosphates; Volumetric determination of ——. F. X. Moerk. Amer. J. Pharm., 1922, 94, 641—650.

PHOSPHORIC acid and disodium phosphate can be determined volumetrically by titration with sodium hydroxide and hydrochloric acid respectively, using a mixture of methyl orange and indigo-carmine as indicator. To obtain results by this method in consistent agreement with the silver phosphate precipitation method followed by titration the liberated acid with alkali hydroxide up the permanent formation of brown silver xide, the dilution of the reacting solutions must be specified and a definite quantity of odium chloride, depending on the dilution, must e added; the silver phosphate method is not pparently affected by these factors. For the eutralisation method using the indicator the rocedure is as follows. To 100 c.c. of water r salt solution, 0·2 c.c. each of 0·1% methyl range solution and 0·3% indigo-carmine solution are added, followed by dilute hydrochloric cid until the green colour changes without producing a violet colour. The indicator solution thus repared is divided into two equal parts, one being eserved, and the other added to the phosphoric acid olution to be estimated, and the mixture titrated with *N*/2 sodium hydroxide or hydrochloric acid, as the case may be, to match the tint of the eserved solution. The end point corresponds in each case to the formation of NaH_2PO_4. Under these conditions results in agreement with the silver phosphate method were obtained by titrating in presence of 7·5% sodium chloride for phosphoric cid and 2·5% for the phosphate. Under similar conditions sodium pyrophosphate can be titrated with acid as a di-acid base.—G. F. M.

Phosphoric acid and sodium phosphate; Methyl red in the assay of ——. F. X. Moerk and E. J. Hughes. Amer. J. Pharm., 1922, 94, 650—655.

HE U.S.P. (IX) method for the volumetric etermination of phosphoric acid and phosphates lways gives lower results than either of the wo methods described in the preceding abstract. he mixed indicator method is the most rapid, ut is influenced by the weight of substance aken, by the amount of sodium chloride present, nd by the strength of the volumetric solutions. The est results when working with unknown quantities re obtained by the silver phosphate method, trating back the liberated acid with alkali hydroxide, using methyl red as indicator. The procedure is as follows: To 50 c.c. of standard lver nitrate solution one drop of methyl red and trace of alkali to produce a yellow colour are dded, followed by 10 c.c. of the solution to be sayed. The liberated nitric acid (3 mols. per mol. H_3PO_4, or 1 mol. per mol. of Na_2HPO_4) is titrated th alkali hydroxide until the supernatant liquid again yellow. During the titration the pink lour may fade, in which case one or two drops more methyl red must be added.—G. F. M.

lcium carbide. E. Botolfsen. Ann. Chim., 1922, 18, 5—48.

RBIDE was prepared by direct combination of mmercial calcium, from which the coating of ide had been removed, and lampblack, previously rified by heating to redness in a current of lorine. An excess of calcium was used and conct between the elements was effected by piercing les in the metal and placing the carbon therein. The mixture was then heated *in vacuo*, but no appreciable reaction took place at temperatures below the melting-point of the metal, even when heating to 700° C. was continued for 50 hrs. Carbide was formed when the metal fused, but distillation of the metal proceeded faster than the reaction, so that carbon containing only traces of carbide remained. On heating in an atmosphere of argon at normal pressure for 6 hrs. at 800°—850° C., no volatilisation of calcium occurred, but no increase in the formation of calcium carbide was observed. Further attempts made with calcium vapour were successful, and on heating 5 g. of calcium and 2 g. of carbon at 850°—875° C. for 17 hrs. only 7% of the carbon remained uncombined, whilst in the case of 11 g. of calcium heated with 5 g. of carbon at 1025°—1050° C. for 10 hrs., only 1·5% of free carbon remained. Finally when 14 g. of calcium was heated with 4 g. of carbon at 925°—975° C. for 45 hrs., all the carbon was converted into carbide. The excess of calcium was found as a metallic deposit in the upper part of the tube. Pure carbide, as described by the author, is white, but the substance prepared by the above method is black. It rapidly decomposes in air, yielding acetylene; the resulting lime is whiter than that obtained from industrial carbide, so that the colour is not due to the presence of free carbon; moreover industrial carbide containing up to 6% of carbon is grey. Experiment showed that the colour was due to iron from the containing vessel, but further specimens made in an alundum tube were also black. In the latter case, analysis showed the presence of metallic aluminium formed by the action of calcium on alumina. The dissociation of commercial carbide was effected by heating 3 g. to 1050° C. for 18 hrs., when a deposit of several centigrams of metallic calcium was obtained in a finely divided condition. When an iron vessel is used for the purpose, the carbon liberated attacks the vessel with the formation of Fe_3C. No trace of a sub-carbide of calcium was found. The presence of certain substances, *e.g.*, iron and iron oxide, affects the progress of the dissociation.

—H. J. E.

Magnesium sulphate; The octahydrate of ——. S. Takegami. Mem. Coll. Sci. Kyoto, 1921, 5, 191—199.

WHEN magnesium sulphate crystallises from aqueous solutions containing sodium sulphate at 25° C. it separates as the octahydrate, which has not previously been recognised. If the proportion of sodium sulphate is increased, astrakanite $MgSO_4,Na_2SO_4,4H_2O$, is eventually formed. At 30° C., however, when the proportion of sodium sulphate is increased to about 32 mols %, the octahydrate is transformed into heptahydrate. The octahydrate changes into heptahydrate when air-dried. In a magnesium sulphate—sodium sulphate—water system containing 7—9% of sodium sulphate in solution, the octahydrate of magnesium sulphate is stable below 45·5° C. and the heptahydrate from this temperature to at least 77·2° C. The number of solid phases to be taken into account in the equilibrium of the reciprocal salt pair

$$MgSO_4+2NaCl \rightleftharpoons MgCl_2+Na_2SO_4$$

thus becomes, with the addition of $MgSO_4,8H_2O$, ten.—E. H. R.

Calcium carbonate; Solubility of —— *in water in equilibrium with a gaseous phase containing carbon dioxide.* Y. Osaka. Mem. Coll. Sci. Kyoto, 1921, 5, 131—141.

A THEORETICAL paper, in which, assuming for the first and second apparent dissociation constants of carbonic acid the values $3·5\times10^{-7}$ and $4·91\times10^{-11}$, but allowing for the fact that carbon dioxide dissolved in water is combined only to a small extent and that carbonic acid is in reality a much stronger acid than acetic acid, the solubility product of calcium carbonate (calcite form) at 25° C. is calculated to be $7{\cdot}24\times10^{-9}$. A formula is given from which the solubility of calcium carbonate at any partial pressure of carbon dioxide can be calculated, assuming the degree of dissociation of calcium bicarbonate to be the same as that of calcium acetate at the same concentration.—E. H. R.

Rare earths; A new mineral which contains the —— as its main component. F. Henrich and G. Hiller. Ber., 1922, 55, 3013—3021.

A HYDRATED phosphate of yttrium and erbium, PO_4(ErY etc.), $2H_2O$, termed weinschenkite, occurs in very small quantity in the Bavarian Oberpfalz in white, matted, globular deposits and in radiating needles on brown hæmatite from which it is readily detached. An accurate quantitative analysis of the mineral has not yet been possible owing to the small quantity available. (*Cf.* J.C.S., Dec.)—H. W.

Radium solutions; Durability of ——. A. Becker. Z. anorg. Chem., 1922, 124, 143—152.

THE permanency of the solution is defined as its constancy of emitting emanation. The author found that solutions containing 0·02 to 0·0000005 mg. of radium per grm. of solvent did not show any decay in eight years. The possible experimental error was 1%.—W. T.

Gels of inorganic salts; General method for obtaining ——, and its relation to theories of the colloidal state. K. Charitschkov. J. Russ. Phys.-Chem. Soc., 1920, 52, 91—96.

THE action of hydrogen chloride or carbon dioxide on a solution of sodium (potassium etc.) naphthenate in a hydrocarbon containing excess of naphthenic acid yields colloidal sodium chloride or carbonate; oleic acid may be used in place of naphthenic acid. The products thus obtained, including colloidal cupric and mercuric chlorides, etc., exhibit Brownian movement and the corresponding ultramicroscopic appearance. When ferric naphthenate is treated with hydrogen chloride, the latter exerts a reducing action, the product being ferrous chloride. (*Cf.* J.C.S., Dec.)—T. H. P.

Salts; Adsorption of —— on metal surfaces. H. von Euler and G. Zimmerlund. Arch. Kem. Min. Geol., 1922, 8, [14], 1—23.

MEASUREMENTS have been made of the silver nitrate and potassium chloride adsorbed from aqueous solution by finely divided gold particles and by gold-leaf. The amount adsorbed increases with the amount of salt in solution, at first linearly and then tending to a maximum. At the maximum there is more adsorbed than would correspond to a unimolecular layer on the gold. Experiments are also described with mercury dropping through a calomel solution, in which the amount of mercury in solution was determined by measuring its effect as an enzyme poison.—W. O. K.

Phosphorus. W. Marckwald and K. Helmholz. Z. anorg. Chem., 1922, 124, 81—104.

THE authors found the melting point of scarlet phosphorus to be 592·5°±0·5° C., and the critical temperature of the yellow modification 720·6° C. By rapid cooling of phosphorus vapour a mixture of the yellow and scarlet modifications is deposited, whilst slow cooling gives the pure yellow form. A hypothesis is advanced to explain this and also the phenomenon observed on cooling liquid scarlet phosphorus (*cf.* J.C.S., Dec.). The authors show that the crystals isolated from the melt of the scarlet variety are identical with Hittorf's phosphorus. Black phosphorus changes into the scarlet form on being heated to 575° C.—W. T.

Naturally occurring gases; Examination of —— II. F. Henrich and G. Prell. Ber., 1922, 55, 3021—3025.

THE method for the collection and examination of naturally occurring gases (*cf.* J., 1920, 748 A) has been simplified and extended. The gases from three springs near Leopoldsdorf, Bavaria, contained respectively oxygen 13%, with nitrogen and rare gases, oxygen 18·8%, with nitrogen and rare gases, and oxygen 18·2%, nitrogen 81·8%, argon and neon 1·1%. Since the ratio, nitrogen : rare gases in the gases is approximately the same as in air, it appears that air has in some manner been enclosed below the water in the spring. The low oxygen content of the gases in comparison with that of air is explained by the greater solubility of oxygen than of nitrogen in water. (*Cf.* J.C.S., Dec.)—H. W.

Naturally occurring gases; Examination of —— III. F. Henrich and G. Prell. Ber., 1922, 55, 3026—3030.

THE gases from a number of pools on the Luisenbur near Wunsiedel and Alexanderstad (Fichtelgebirge consisted mainly of nitrogen (and rare gases) and methane, with small quantities of oxygen and carbon dioxide and traces of hydrogen sulphide. The methane, carbon dioxide and hydrogen sulphide appear to owe their origin to a bacterium which is similar to but not identical with *B. methanigenes*. Nitrogen and the rare gases must be derived initially from the air. The ratio of rare gas to nitrogen is, however, in two instances rather more than 50% greater than in air. It is suggested that the air was imprisoned beneath the water and a portion of its nitrogen was assimilated by bacteria.—H. W.

PATENTS.

Gas and carbonaceous materials [calcium carbide]; Production of ——. J. H. Reid. E.P. 185,135, 22.2.21.

COAL ground to pass through an 8-mesh sieve and calcium carbonate ground to pass a 40-mesh sieve are intimately mixed and carbonised in a retort at 2600°—2800° F. (1400°—1550° C.). The tarry distillate produced at lower temperatures is not formed, the sole products from 4000 lb. of limestone and 4000 lb. of coal being 27,000 cub. ft. of gas of high calorific value and 6520 lb. of coked residue. The latter is passed at a high temperature to an electric furnace, where it yields 3000 lb. of calcium carbide and 90,000 cub. ft. of carbon monoxide. An improved current efficiency in the carbide furnace is obtained due to the uniformity of the charge. If desired the molten carbide may be run into water and the resulting acetylene and hydrogen led back through the furnace chamber, wherein the mixture is converted into hydrocarbons such as methane, ethylacetylene, and methylallene.—C. I.

Alkali from felspar and other minerals; Process for the extraction of ——. Plauson's (Parent Co.), Ltd. From H. Plauson. E.P. 186,199, 15.7.21.

TEN pts. of finely ground felspar is allowed to stand for some time with 10 pts. of a 10% solution of hydrochloric acid. The mixture is then diluted with 40 pts. of water and submitted to a treatment in a colloid mill. The colloidal dispersion so obtained is heated to about 225° C. at 25 atm. pressure in an autoclave, whereupon a large proportion of the potash in the felspar goes into true solution. The solution is filtered and concentrated by evaporation

A more refractory mineral requires treatment at high pressure with superheated steam at 125°—350° C. Extraction of the potash is facilitated if the felspar is heated in a "revolver" furnace with carbonaceous material or heated with reducing gases before being subjected to the process.—H. R. D.

Hydrogen peroxide; Production of ——. Woodlands, Ltd. From J. Pátek. E.P. 186,840, 12.10.21.

Solutions of hydrogen peroxide, or solutions (persulphates) which yield it on heating, are sprayed or atomised on to a surface of sulphuric acid or fused sodium bisulphate heated to a temperature above the boiling point of the solution. The hydrogen peroxide evaporates immediately and escapes with the steam to a condenser, in which it is rapidly condensed.—H. R. D.

Ferrous sulphate; Method of oxidising ——. C. J. Herrly, Assr. to Union Carbide Co. U.S.P. 1,430,551, 3.10.22. Appl., 13.7.20.

Ferrous sulphate is subjected to the action of oxygen with an oxide of nitrogen as catalyst, in presence of water and sufficient sulphuric acid.
—C. I.

Dicalcium phosphate; Manufacture of ——. M. Helbig. G.P. 357,763, 3.7.20.

Raw materials containing tricalcium phosphate are dissolved in mineral acid and the solution is heated in the presence of a quantity of magnesium chloride sufficient to provide chlorine ions equivalent to at least half of the calcium present.—L. A. C.

Aluminium compounds; Preparation of —— nearly free from iron from solutions of ferruginous alumina. Chem. Fabr. Griesheim-Elektron. G.P. 357,900, 1.8.19.

Ferric salts present in aluminium solutions are reduced to ferrous salts and the aluminium salts in solution are converted into insoluble compounds by evaporation and thermal decomposition in the absence of air.—L. A. C.

Copper sulphate; Production of —— from waste material containing copper or its alloys. S. Hiller. G.P. 358,611, 2.9.20. Conv., 24.8.20.

An intimate mixture of waste material containing copper or its alloys and not more than 10% of its weight of sodium chloride is roasted as in the chloridising roasting of copper sulphide ores, and is subsequently treated with sulphuric acid. If the material contains tin, a small proportion of calcium oxide, silica, or alumina is added before roasting.
—L. A. C.

Graphite; Purification of —— by means of an electric current. Graphitwerk Kropfmühl A.-G. G.P. 358,520, 13.3.19.

A mixture of graphite and coal is heated above 2200° C., whereby impurities combined with the graphite are sublimed. By allowing the sublimed vapour to condense at different temperatures, the various impurities may be recovered separately.
—L. A. C.

VIII.—GLASS; CERAMICS.

Quartz; Elasticity and symmetry of —— at high temperatures. A. Perrier and B. de Mandrot. Comptes rend., 1922, 175, 622—624.

A study of the variation in the elasticity of quartz with change of temperature showed that decreasing values are obtained up to 575° C., whilst beyond that point the values increase at first very greatly for small increments of temperature, then to a gradually diminishing extent. At the inversion point (transition from α- to β-quartz) the crystal passes from the rhombohedral to the hexagonal system.—H. J. E.

Patents.

Glass furnaces; Feed troughs for ——. W. G. Clark. E.P. 163,995, 27.5.21. Conv., 27.5.20.

The feed trough of a glass furnace is provided internally with an electric heating element which enables chilled glass in the trough to be melted whilst the batch in the furnace is being heated. As soon as the glass is melted the current may be directed through the molten glass.—C. A. K.

Clay; Treatment of ——. W. Feldenheimer and W. W. Plowman. E.P. 186,855, 21.11.21. Addn. to 184,271 (J., 1922, 756 a).

The clay is deflocculated in a dilute aqueous solution of sodium or potassium pyrophosphate.
—H. R. D.

Artificial meerschaum; Method of producing ——. P. Deussing. E.P. 172,004, 18.11.21. Conv., 23.11.20. Addn. to 164,319.

See G.P. 340,533 of 1920; J., 1921, 892 a.

Refractory material. E. D. Frohman. E.P. 186,968, 10.6.21.

See U.S.P. 1,372,016 of 1921; J., 1921, 348 a.

Clays; Treatment of —— and manufacture of articles and materials therefrom. W. Smith. U.S.P. 1,432,629, 17.10.20. Appl., 1.9.21.

See E.P. 149,440 of 1919; J., 1920, 658 a.

IX.—BUILDING MATERIALS.

Patents.

Wood; Method of treating ——. F. B. Dehn. From The Studebaker Corp. E.P. 187,018, 12.7.21.

Wood is treated with a liquid mixture such as that made by mixing 30 lb. of Manila gum, 3 galls. of Baltic linseed oil, and 7 galls. of turpentine and adding zinc oxide ground in varnish in the proportion of 8 lb. per gallon of the first mixture. The treated wood is gradually heated for 3 hrs. to a temperature above its critical point or for 4 hrs. to 200° F. (93° C.). After this treatment the strength of the wood is greatly increased and its critical temperature raised.—A. R. P.

Slag; Method for obtaining highly porous ——. C. H. Schol. E.P. 145,032, 14.6.20. Conv., 29.8.14.

See U.S.P. 1,163,605 of 1915; J., 1916, 118.

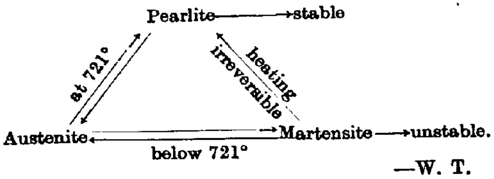
X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Iron-boron-carbon; The ternary system ——. R. Vogel and G. Tammann. Z. anorg. Chem., 1922, 123, 225—275.

The authors discuss the results of Hannesen (J., 1915, 84) and Tschischewsky and Herdt (J., 1917, 650) who investigated the system iron-boron. The disagreement of their results is found to be due to differences in the rate of cooling. Rapid cooling results in the separation of supersaturated mixed crystals. Hannesen worked with small quantities and the cooling was much more rapid than in the work of Tschischewsky and Herdt. The authors have carried out a systematic study of the ternary system iron-boron-carbon and their results are given in detail. Equilibrium sets in so slowly in the system that the structure and properties of the ternary alloys depend to a large extent on the preliminary heating. The limiting proportion of boron having an influence on the structure was found to be 0·02%.—W. T.

Steels; Honda's conception of the A1 transformation and the quenching of ——. M. Chikashige. Z. anorg. Chem., 1922, **124**, 59—60.

A THEORETICAL paper in which the author criticises the views of Honda (J., 1919, 821 A), and claims that a better interpretation is given by the following scheme:—



—W. T.

Steels; Influence of velocity of cooling on the position of the critical points and the structure of ——. W. Schneider. Stahl u. Eisen, 1922, **42**, 1577—1584.

THREE carbon steels, A, B, and C, containing 0·30, 0·89, and 1·25% carbon and 0·14% manganese, were used. Ball specimens 10 mm. diameter were prepared from rods of these steels, and the Portevin water resistance was used to regulate the cooling velocities. The Ac1 and Ar1 points of the steels were 726°, 725°, 725° C. and 715°, 716°, 716° C. respectively. The effect of increasing the cooling velocity on the Ar1 points is to produce a distinct lowering, whilst increasing heating velocity produces a not inconsiderable raising of the Ac1 points. The pearlite point is lowered by increasing the initial temperatures. It is suggested that this change is due to "crystal nuclei" which remain in the solid solution. The higher the temperature as primary cause and the longer the time of cooling as secondary cause, the smaller the number of "crystal nuclei" which remain to initiate decomposition of the solid solution on cooling. Microscopical examination shows that the grain size decreases with increasing cooling velocities. Quenching tests with water at different temperatures showed that steel A is troostitic even with the quenching bath as low as 20° C., the cooling curve showing the upper critical point. In steel B the change point is lowered and martensite appears after quenching in water at 50° C. Steel C shows the evolution of heat in the low temperature regions with quenching in water at 50° C. For the retention of martensite in hypoeutectoid steels, the lower the carbon, the lower must be the temperature of the quenching bath, but with steels containing 0·9% carbon and over, such differences no longer exist. It is indicated by all the tests that martensite is formed with evolution of heat, and it is accepted that in the formation of troostite and martensite, of the whole of the heat absorbed at the Ac1 point, does not become free on cooling, the remainder being retained latent by the structural constituents.

—J. W. D.

Titanium; Estimation of —— in ferrous products. L. Losana and E. Carozzi. Giorn. Chim. Ind. Appl., 1922, **4**, 394—396.

THE method is based on the oxidation of titanous to titanic compounds by methylene blue (*cf.* Ferrari, J., 1920, 837 A), which is found to be without action on other usual constituents of irons and steels. Solutions of 3·9 and 1·95 g. per l. respectively of methylene blue, corresponding with about 0·001 g. and 0·0005 g. of titanium per c.c., are convenient, the exact titres being determined experimentally. (1) *Steels and cast irons*: Of these, which seldom contain as much as 1% of titanium, 2—5 g. of the sample is evaporated gently to dryness with hydrochloric acid diluted with its own volume of water, the dry residue being heated on a water-bath for 15 mins. with concentrated hydrochloric acid to dissolve the whole of the titanium. The liquid is diluted to 200—300 c.c. and treated for 30 mins. at 60° C. with 25 c.c. of concentrated hydrochloric acid and a few grams of zinc dust. As the titanium reacts only after the iron, the liquid is tested to ensure the complete reduction of the iron, and is then filtered rapidly, through a glass wool plug on which is placed a little granulated zinc, into a flask filled with carbon dioxide, the filtrate being titrated immediately with the methylene blue solution until a distinct coloration appears. (2) *Ferro-titaniums*: Since these are insoluble in acids, 0·5 g. of the finely-divided metal is fused with potassium bisulphate, the mass being then digested with 50% hydrochloric acid on a water-bath for 20 mins. and the liquid made up to a definite volume. The reduction and titration, as described above, are then carried out with an aliquot part. The method yields satisfactory results provided that the reduction, filtration, and titration are effected rapidly.—T. H. P.

Ferrosilicon; Toxic properties of commercial ——. N. Kurnakow and G. Urasow. Z. anorg. Chem., 1922, **123**, 89—131.

COMMERCIAL ferrosilicon has been found to evolve poisonous and explosive gases. The alloy containing about 50% Si is sensitive to water and is very dangerous. The authors found that in iron-silicon alloys with 33·4 to 100% by weight of silicon, a solid phase of variable composition (55·18—61·5% Si) was formed, which solidified at 1245° C. This phase (lebeauite) can form ternary and quaternary solid solutions with phosphorus and aluminium. The ternary solid solutions (Fe-Si-P and Fe-Si-Al) of lebeauite are stable towards water. The quaternary solution of lebeauite (Fe-Si-P-Al) is attacked by water, phosphine being evolved. Ferrosilicon with less than 33·4% Si and containing γ-iron will dissolve phosphorus and aluminium to the extent of 1·7% and 3% respectively. These ternary and quaternary solutions resist the action of water. Calcium phosphide will dissolve neither in solid nor in liquid ferrosilicon.—W. T.

Non-ferrous alloys; Use of —— under superheat. H. C. Dews. Engineering, 1922, **114**, 541—542.

THE behaviour of copper and its principal commercial alloys at high temperatures is discussed with especial reference to their tensile strength and ductility, and a number of curves showing the alteration of these properties with the temperature are given. The tensile strength of copper falls rapidly with increasing temperature up to 700° C., then much more slowly, while its ductility decreases slowly to the same temperature, then very rapidly increases. Similar curves are obtained for 70:30 brass with the bend in the tensile strength curve at 550° C. and the minimum ductility at 400° C., while in 60:40 brasses the tensile strength curve bends much more sharply at 475° C. Probably the most suitable alloys for engineering materials at high temperatures are those of copper and nickel, some of which, *e.g.*, the 80% Cu, 20% Ni alloy, have a tensile strength and ductility at 500° C. equal to that of gun metal at ordinary temperatures.

—A. R. P.

Binary alloys; Relation between the equilibrium diagram and hardness in ——. T. Isihara. Sci. Rep. Tôhoku Imp. Univ., 1922, 11, 207—222.

THE maximum hardness of copper-nickel alloys occurs when the alloy consists of atomic proportions of nickel and copper and is not affected by annealing or ageing. This agrees with Tammann's theory of the hardness of binary alloys orming continuous solid solutions. Quenching of ron-copper alloys containing less than 20% Cu ncreases the hardness to a degree depending on the emperature at which quenching takes place, and he curve showing the relation between quenching emperature and hardness shows breaks at the Ar 2 and Ar 3 points, the Ar 3 point being very marked. On ageing, the hardness first increases slightly, then decreases. In the aluminium-zinc series the hardness-quenching temperature curve shows a break at 262° C. in alloys containing 5—68% Al, corresponding to the transformation of the β phase into $\alpha+\gamma$. Quenching of these alloys from above the eutectoid point results in a considerable increase in hardness, while ageing increases the hardness only of alloys in the $\beta+\gamma$ region. The hardness of the copper-tin alloys substantiates Heycock and Neville's diagram of their constitution (Phil. Trans., 1904, **A 202**); ageing has little effect on the hardness. In the copper-aluminium series quenching from a temperature above the eutectoid point considerably decreases the hardness instead of, as in the case of steels, increasing it, thus showing the incorrectness of the interference theory of hardness (Jeffries and Archer, J., 1921, 515 A). It is shown that Hayward's theory (Chem. Met. Eng., 1921, **65**, 695) that the central portion of an annealed steel bar is harder than the outer portion owing to variation of thermal stress from the centre towards the periphery, is improbable and that the results observed are due to the edge effect, the portion of metal near the edge having a smaller resistance to deformation than the central part of the bar.—A. R. P.

Metal; Effect of temperature, pressure, and structure on the mechanical properties of ——. Z. Jeffries and R. S. Archer. Chem. and Met. Eng., 1922, **27**, 747—751.

THE temperature scale of a solid metal can be divided roughly into a region, below atmospheric temperature, in which the metal is brittle, an intermediate region extending up to the temperature of recrystallisation, and a zone of hot working lying above the temperature of recrystallisation. Pressure applied uniformly on a metal does not effect any permanent change in structure or properties, as metals are perfectly elastic. Hardness increases with the pressure especially for soft materials. It is difficult to describe the structure of a metal with reference to the orientation of its grains. Ordinarily the grains possess varied orientations, but a certain uniformity of orientation occurs in cold-worked metals which persists to some extent after annealing. Fine grain is held generally to promote toughness, strength, and ductility, but at high temperatures it leads to flow at the grain boundaries especially under prolonged application of a load. Cold deformation produces refinement of grain in the sense that one original grain exhibits a mixture of orientations after severe cold work, but the directional properties of the metals are never obliterated. Failure of crystals under load always takes place on crystallographic planes and the only "strength property" of a single crystal is its elastic limit in shear, which has a different value in different crystallographic directions. The properties of crystals depend on the characteristics of the constituent atoms and on the type of space lattice arrangement. All metals crystallising with the face-centred cubic arrangement are ductile throughout a wide range of temperature. Ductile metals possess the property of limiting the extent of slip on any one plane and transferring the successive movement to another slip plane without actual rupture of the first.—C. A. K.

Metals; Mechanical properties of —— as affected by grain size. Z. Jeffries and R. S. Archer. Chem. and Met. Eng., 1922, 27, 789—792.

BELOW the recrystallisation temperature grain boundaries of metal crystals retard plane slip due to variation of orientation of the adjacent crystals and the presence of amorphous metal. Decrease in size of grain would therefore tend to increase the strength and hardness of a metal. The quantitative relation of strength to grain size is dependent on the number of grains on the cross-section, though when this number becomes relatively large (1000 or more) the absolute grain size is more important. Fracture takes place normally through the grains when a ductile metal is broken "cold," but at temperatures just below the melting point grain boundaries are sources of weakness and the fracture is intergranular. The grain size conducive to maximum elongation is neither very fine nor extremely coarse, this property being influenced by the size and shape of the test-piece, temperature conditions, and rate of loading. Lower values for elongation are observed generally in test-pieces of small section. Brittleness may be due to the hardness of amorphous metal at the grain boundaries, although the individual crystals are plastic, *e.g.*, in tungsten, or may be due primarily to the brittle character of the crystal itself, *e.g.*, in zinc. Under tensile strain for reduction of area metals at high temperatures somewhat resemble soft glass, since the hardening effect of the deformation is removed by spontaneous annealing. The reduction of area of single crystals is very high, and extremely small grain size, such as probably occurs in hardened steel, is unfavourable to plasticity of any kind; ordinarily the reduction in area is greater the smaller the grain size.—C. A. K.

Metals; Behaviour of two —— towards one another when dissolved in mercury. G. Tammann and W. Jander. Z. anorg. Chem., 1922, **124**, 105—122.

THE authors investigated the affinity of one metal for another when dissolved in mercury by measuring the freezing point depression of the compound crystals and comparing this with that of the components, and by measuring the influence of the one metal on the e.m.f.-concentration curve of the other dissolved in a third, more noble liquid metal. Thus the addition of small amounts of a more noble to a less noble metal has but a very small effect on the e.m.f. if the compound of the two metals is very highly dissociated, whereas if a stable compound is formed, then a sudden change in the e.m.f. is caused when the concentrations of the metals correspond to the composition of this compound. The following intermetallic compounds were found to be very stable: $AuZn$, Mg_2Sn, $CeSn_2$ and Ce_4Bi_3. Others were very highly dissociated in solution in mercury, for example, compounds of gold with cadmium and lead, of silver with zinc and cadmium, of copper with zinc and cadmium.—W. T.

Metals; Velocity of the action of oxygen, hydrogen sulphide, and the halogens on ——. G. Tammann and W. Köster. Z. anorg. Chem., 1922, **123**, 196—224.

WHEN iodine, chlorine, or air acts on a metal, various surface colours are formed and these colours can be employed as a means of determining the rate of thickening of the film of compound formed (*cf.* J., 1920, 519 A). The rate of chemical action is assumed to be high, but diffusion through the film of compound formed is slow. The rate in the case of iodine is inversely proportional to the thickness of the film and is independent of the temperature. Silver iodide exists in two forms; at the transition point, 145° C., there is a change in the rate of reaction. In the case of the action of moist air containing chlorine and bromine on copper, silver, and lead, there is a parabolic relationship between time of action and thickness of the film. Colours due to the formation of films of oxides are formed by heating several metals in the air, the rate of formation being independent of the rate of flow of gas. The rate of increase of thickness of film with time follows an exponential law. At higher temperatures oxidisable metals are immediately covered with a thin film of oxide which protects the metal from further action. The oxidation is much more rapid in moist air. Hydrogen sulphide reacts rapidly with copper and manganese, more slowly with silver, and still more slowly with lead. Iron, cobalt, nickel, chromium, antimony, bismuth, tin, aluminium, zinc, and cadmium show no change after contact with the gas for several days. The action of air on copper-zinc alloys was also investigated.—W. T.

Nitrides [of metals]; Rate of formation of some ——. G. Tammann. Z. anorg. Chem., 1922, 124, 25—35.

The rate of increase in thickness of the film of nitride formed on heating metals in nitrogen was measured by the change in colour of the films. In the case of cerium, lanthanum, and a mixture of the two the rate of increase of the film thickness plotted against the logarithm of the time gave two straight lines cutting in each case at a definite temperature (*cf.* Tammann and Köster, *supra*). The same applies to metals in oxygen. The presence of moisture in the gases greatly accelerates their action. The film of nitride on iron protects the metal. Cobalt, nickel, molybdenum, tungsten, tantalum, and silicon do not change in an atmosphere of nitrogen at 700° C. Magnesium and calcium are converted into their grey nitrides. —W. T.

Patents.

[*Chromium-*] *iron alloys* [*; Production of* —— *of low carbon content*]. J. C. Gillott. E.P. 186,982, 6.7.21.

Chromium-iron alloys of low carbon content, in which the chromium is the minor constituent, are prepared by melting separately ferrochromium of high chromium content and pig-iron or steel scrap or a mixture of these, and tapping each batch of molten metal into a converter where, if not already present, an alloy of silicon and manganese is added so that at least 2% Si is present in the charge. The mixture is blown until the carbon and silicon contents have been sufficiently reduced to allow of the resulting metal being worked, and towards the end of the operation a certain amount of manganese is added.—A. R. P.

Ores [*especially oxidised copper ores*]*; Treatment and concentration of* —— [*by the flotation process*]. H. H. Smith. E.P. 166,888, 11.7.21. Conv., 26.7.20.

A mixture of steam and air is blown through a mixture of carbon and a sulphur-bearing material, *e.g.*, iron pyrites, contained, under a layer of lime, in a retort heated to about 700° C. The evolved gases, consisting chiefly of hydrogen sulphide and carbon dioxide, together with smaller amounts of hydrogen and carbon monoxide, are passed through a thick pulp of ground ore and water until the liquid just shows a sulphide reaction. The pulp is diluted, a frothing and stabilising agent added, and the mixture subjected to a flotation process.—A. R. P.

Flotation processes for concentrating ores and the like. A. C. Vivian. E.P. 186,760, 5.8.21.

In the separation of the more valuable constituents of ores, concentrates, metal products, and like heterogeneous materials, organic substances are added which act chemically upon the metal or metal compound to be separated, forming tarry or resinous complexes or decomposition products which facilitate separation of the metal or metal compounds by flotation. Suitable substances are oximes (phenylglyoxime), isonitroso-compounds (cupferron or nitrosophenylhydroxylamine-ammonium, dinitrosoresorcinol), and amino-acids (taurocholic acid), and they may be used alone or in conjunction with known oiling or frothing agents.—J. W. D.

Furnace for roasting pyrites and like ores; Mechanically operated ——. Manuf. de Prod. Chim. du Nord Etabl. Kuhlmann. E.P. 167,464, 27.6.21. Conv., 5.8.20.

In a roasting furnace of the shelf type the rabble arms are fitted with a series of teeth arranged parallel to one another and obliquely to the axis of the rake, so that the end of one tooth touches the same circle of travel as the adjoining tooth. The individual teeth have the shape of the mould-board of a plough and meet the material substantially in a vertical direction, the off-take angle of the teeth being approximately 45°, the natural piling angle of the material treated. In order to compensate for the increase in resistance against the rakes when they act centrifugally, the teeth are given a slight curvature.—C. A. K.

Bearing metal alloy. T. Goldschmidt A.-G. E.P. 169,703, 27.9.21. Conv., 1.10.20.

An alloy containing 70—75% Pb, 15—25% Sb, 3—6% Sn, 1—3% Ni, and 0·6—1·5% Cu, the copper being introduced in the form of 0·8—2·2% of copper phosphide.—J. W. D.

Rare metals [*e.g., zirconium*]*; Process for the preparation of* ——. Westinghouse Lamp Co., Assees. of J. W. Marden. E.P. 173,236, 21.12.21. Conv., 21.12.20.

A salt of the rare metal which does not volatilise at the temperature of the reaction, or a double salt with another metal, is reduced by heating with aluminium, iron, or other suitable metal in quantity slightly less than the stoichiometric amount, and the heating is continued *in vacuo*, after the reaction has taken place, until all the salts present are volatilised, leaving a residue of the pure rare metal. For example, potassium zirconofluoride is mixed with a little less than the theoretical quantity of aluminium and the mixture is heated in an evacuated vessel in an induction furnace. After the vigorous reaction has taken place the temperature is raised until the aluminium, potassium, and excess zirconium fluorides have volatilised, leaving a greyish spongy mass of pure zirconium. —A. R. P.

Nickel alloys. W. Jones, and Sylvette, Ltd. E.P 186,381, 26.5.21.

A nickel silver alloy containing Al 1—3%, F 2—4%, and to which a small quantity of a deoxidi ing agent, *e.g.*, manganese or magnesium, has bee added, may be cast into the form of such article as forks, spoons, etc. The complete compositio of such an alloy may be Cu 55%, Zn 17%, Ni 22% Al 2·25%, Fe 3%, and Mn 0·75%.—C. A. K.

Nickel; Production of —— from nickel carbonyl. H. E. Fierz and H. A. Prager. E.P. (A) 186,457 and (B) 186,458, 14.7.21.

(A) An apparatus for the decomposition of nickel carbonyl consists of a double-walled rectangular chamber, the sides of which are heated to about 300° C. by the passage of hot gases through the space between the walls. The top and bottom of the chamber are cooled by water and the interior is cooled by a cooling liquid flowing through a series of pipes. Nickel carbonyl is passed through the chamber and is in contact with cooling surfaces except at the side walls where decomposition is effected. By this means a pure compact deposit of nickel forms on the side walls of the reaction chamber which can be detached readily for removal of the nickel. (B) The reaction chamber contains a series of parallel hollow iron plates, spaced apart (¾"), which may be heated internally by the passage of hot gases. Practically all the nickel separates on these plates as a compact coherent deposit. —C. A. K.

Nickel; Manufacture of pure ——. H. Sefton-Jones. From Soc. Anon. "Le Nickel." E.P. 187,111, 16.9.21.

The process is the same as that described in G.P. 355,887 (J., 1922, 765 A) except that the use of hydrochloric acid instead of, or as well as, hydrofluoric acid for washing the metal after the first reduction is claimed. The final reduction process may be carried out with the addition of magnesia or of alkali or alkaline-earth carbonates instead of with lime, the object of these additions being to assist in the removal of sulphur compounds.—A. R. P.

Aluminium alloys. The British Thomson-Houston Co., Ltd. From General Electric Co. E.P. 187,089, 29.8.21.

Alloys of aluminium, copper, and silicon containing at least 50% Al, 25% Si, and 15% Cu are claimed, especially those containing 70% Al, 27·5—15% Cu, and 2·5—15% Si. Within these limits alloys having a scleroscope hardness of 45 and a tensile strength of 21,000—24,000 lb. per sq. in. may be produced, which are suitable for die casting and for the preparation of moulds and cores for the manufacture of rubber goods.—A. R. P.

(A) *[Smelting] furnace.* (B, D, E) *Ore-smelting furnace.* (C) *Smelting of ores.* H. L. Charles. U.S.P. 1,394,470–4, 18.10.21. Appl., 23.1.20.

(A) In an ore-smelting furnace a monolithic arch of highly refractory material, *e.g.*, silica, lime, fireclay, magnesite, chromite, is moulded above the usual firebrick arch, allowed to set, and then baked by means of the furnace gases. (B) An abutment is built up between the side walls of adjacent reverberatory smelting furnaces and is cut away adjacent to the ends of the arch roofs of the furnaces. In the spaces thus formed are abutment plates fitted with screws and bolts, so that the width of the spaces may be varied as desired according to the expansion or contraction of the arch roofs of the furnaces. (C) The hearth of a reverberatory furnace is provided with a dam of refractory material over which the slag flows into a chamber forming an extension of the hearth. In this chamber the slag comes in contact and reacts with lime rock, whereby its specific gravity is reduced and separation of metal from the slag is facilitated. (D) The ore inlet of a reverberatory furnace is surrounded by a water-box closed by a water-jacketed sliding cover. The ore-inlet nozzle is water-jacketed and is mounted so that it can be moved through an arc in order to regulate the distribution of ore in the furnace. (E) Means are provided for water-cooling the refractory material of the furnace flue and of the throttle-ledge over which the hot gases pass from the furnace to the flue.

Thermit mixture. G. W. Merrefield. U.S.P. 1,430,667, 3.10.22. Appl., 25.10.21.

A mixture of 11—13% of aluminium, 70—72% of iron oxide, 10—12% of low carbon steel, and 6—9% of ferromanganese is used as a thermit mixture for manganese-steel.—C. A. K.

White metal. C. E. Hansen. U.S.P. 1,431,113, 3.10.22. Appl., 5.4.22.

A white metal alloy containing copper, nickel, zinc, tin, and cobalt.—C. A. K.

Bearing metals and the like containing embedded material which does not form an alloy with the metal; Manufacture of ——. G. Ising and H. Borofski. G.P. 357,447, 7.12.20.

A mass of large diameter of a metal containing embedded non-metallic material is reduced by drawing or pressing to a small diameter, and is then cast at a relatively low temperature into the desired shape.—L. A. C.

Titanium alloy. A. W. Clement, Assr. to The Cleveland Brass Mfg. Co. U.S.P. 1,431,725, 10.10.22. Appl., 18.12.17.

An alloy containing 5—25% of titanium and an appreciable quantity, but not more than 30%, of chromium, together with iron and an appreciable quantity of molybdenum.—C. A. K.

Acid-proof casting. H. Terrisse and M. Lévy. U.S.P. 1,432,923, 24.10.22. Appl., 8.7.20.

Electric battery [electrode]. R. C. Benner and H. F. French, Assrs. to National Carbon Co. U.S.P. 1,393,739, 18.10.21. Appl., 16.1.19.

In order to increase the useful life of the cells and to decrease corrosion of the zinc electrode in electric cells, especially dry cells, the zinc is plated with bismuth, or a bismuth compound is mixed with the usual paste placed in contact with the zinc, or, in non-paste cells, bismuth chloride is applied to the surface of the lining of bibulous material in contact with the zinc.

Lead accumulators; Viscid electrolyte for ——. P. Weber. G.P. 358,409, 21.4.21.

A viscid mixture of sulphuric acid with a non-setting mass of plaster of Paris and fine charcoal, kieselguhr or other inert substance is employed as electrolyte in lead accumulators.—J. S. G. T.

Aluminium; Manufacturing electric coils of ——. E. W. Küttner, Assr. to The Chemical Foundation, Inc. U.S.P. 1,431,237, 10.10.22. Appl., 5.9.18.

In the manufacture of electric coils from wires or bands of aluminium or aluminium alloys, the metal is treated with an oxidising agent both prior and subsequent to winding into coil form.—T. A. S.

Purifying liquids; Method of and apparatus for [electrically] ——. F. W. Mitchell and J. E. Pfeffer. U.S.P. 1,431,245, 10.10.22. Appl., 2.8.18.

Liquid is forced by means of compressed air through a cylindrical vessel fitted with spaced perforated electrodes.—T. A. S.

Electric furnace with suction device for gases. A. Helfenstein. G.P. (A) 356,424, 17.3.17, (B) 356,425, 12.4.17, and (C) 356,426, 13.6.17.

(A) The furnace shaft is provided with gas outlets to which are attached gas-discharge tubes, the latter being so arranged that they serve as the fire-tubes of a boiler for generating steam. The infiltration of air and the consequent splintering of parts of the furnace and the formation of explosive mixtures are thus prevented. (B) The gas conduits and the steam boiler are disposed approximately vertically. In like manner the socket for connecting the gas conduit is arranged vertically within the furnace shaft and the boiler connected thereto axially. Dust reaching the gas conduit is in this manner prevented from remaining there, and heat interchange is not reduced owing to this cause. (C) The gas conduits are built into the masonry of the furnace, and the steam boilers are built into the gas conduits near the walls of the furnace shaft and of the shaft for charging the furnace. Gas conduits provided on both sides of the furnace are joined together at the end of the furnace, and vertical fire-tube boilers are arranged at the junction so as more efficiently to utilise the heat of the furnace gases prior to their discharge. Cylindrical boilers may be employed.

XII.—FATS; OILS; WAXES.

Fat constants; Relationships between ——. J. Lund. Z. Unters. Nahr. Genussm., 1922, **44**, 113—187.

The temperature coefficients of the sp. gr. and refractive indices of a number of representative oils and fats and of their insoluble fatty acids were found to average 0·00066, 0·00036, and 0·00068, 0·00037 per 1° C. respectively. The presence of free fatty acids increases the saponif. and iodine values of fats and decreases the sp. gr. and refractive indices. Non-fatty matter and higher alcohols decrease the saponif. and iodine values and increase the sp. gr. and refractive indices. The difference between the constants of fats and those of their insoluble fatty acids is accurately expressed by the following formulæ in which S=saponif. value, N= neutralisation value, I_g, I_f, D_g, D_f, R_g, R_f, repr sent the iodine values, sp. gr.×1000 and refractiv indices×1000 of the glycerides and free fatty acid respectively, while K_s, K_d, and K_r are constant usually 0·000236, 0·112, and 0·051 respectively $N—S=K_sS^2$, $I_f—I_g=K_sI_gS$; $D_g—D_f=K_dS$; R_g— $R_f=K_rS$. The equations for the chemical con stants apply to fats and oils of mean molecula weight (saponif. value 181—198) without referenc to their constitution. The equations for th physical constants apply to ordinary aliphatic fat and oils of average molecular weight, but are no entirely independent of their constitution. Th differences remain almost unaffected by hydrogenating the oils or fats. If the constants of a fat ar known, those of its fatty acids can be accuratel calculated by means of these formulæ except i certain cases in which soluble, cyclic or oxyacids ar present. The formulæ apply to polymerised oil and fats, but these show certain irregularities. I the case of waxes the relationships are different, particularly in the case of the sp. gr., a fact which can be made use of in analysis. The constants of the aliphatic glycerides and fatty acids are related by the following equations:

$$D_g = 847{\cdot}5 + 0{\cdot}3S + b\,I_g$$
$$R_g = 1468{\cdot}5 — 0{\cdot}08S + c\,I_g$$

where b=0·14 to 0·16 and c=0·10 to 0·11.

$$D_f = 847{\cdot}5 + 0{\cdot}18N + b_1I_f$$
$$R_f = 1468{\cdot}8 — 0{\cdot}125N + c_1I_f$$

where b_1=0·135 to 0·155 and c_1=0·095 to 0·105

Tables are given showing the exact values of these factors for the whole range of saponif. and iodine values. The constants of fats containing glycerides of oxyacids, and those of their free fatty acids, are connected by the equations:

$$D_{15} = 847{\cdot}5 + 0{\cdot}3S + 0{\cdot}14I + e\ \text{Ac.}$$
$$R_{40} = 1468{\cdot}8 — 0{\cdot}08S + 0{\cdot}11I + f\ \text{Ac.}$$

where e=about 0·32 and f=about 0·06, and Ac=acetyl value.

Those for fats containing glycerides of cyclic acids by

$$D_{15} = 847{\cdot}5 + 0{\cdot}3S + 0{\cdot}14I + g[\alpha]_D$$
$$R_{40} = 1468{\cdot}8 — 0{\cdot}08S + 0{\cdot}10I + h[\alpha]_D$$

where g=about 0·50 and h=about 0·16.

Constants for polymerised oils are related by t equations

$$D_{15} = 847{\cdot}5 + 0{\cdot}3S + 0{\cdot}14I_g + 0{\cdot}44\,(I_g—I_p)$$
$$R_{40} = 1468{\cdot}8 — 0{\cdot}08S + 0{\cdot}105I_g + 0{\cdot}11\,(I_g—I_p)$$

where I_p is the iodine value after polymerisatio By using these equations, if any two of the four co stants are determined experimentally the other t can be accurately calculated. Ordinary glycerid can be distinguished from those oxy-fatty acid cyclic fatty acids or from polymerised oils, but t use of the equations throws no light on cases adulteration. The melting points of fats and the free fatty acids cannot be co-ordinated with t above-mentioned constants owing to the complic tions caused by the presence of mixed glycerides.
—H. C. R.

Solid and liquid fatty acids; Separation of — W. Meigen and A. Neuberger. Chem. Umscha 1922, **29**, 337—342.

Various published methods were tested on know mixtures of solid and liquid fatty acids, but none was a true quantitative separation obtaine By the methods of Bull and Fjellanger (Apoth Zeit., 1916, **31**, 55), Fachini and Dorta (J., 191 397), and David (J., 1910, 1395) only about one-ha of the liquid acids was recovered in a nearly pu state. By precipitating the aqueous solution of th potassium salts with excess of thallous sulphat however, an almost quantitative separation o stearic, palmitic, and elaïdic acids from oleic acid was attained, and no recrystallisation was necessary. A mixture of 0·502 g. of oleic acid with 0·505 g. of stearic acid gave 0·509 g. of solid acids of iodine value 0·3 and m.p. 68° C., while a mixture of 0·200 g. of oleic acid and 0·502 g. of stearic acid gave 0·529 g. of solid acids of iodine value 0·9 and m.p. 67·5° C.—H. C. R.

Rancidity [*in oils and fats*]; *Influence of air, light, and metals on the development of* ——. J. A. Emery and R. R. Henley. J. Ind. Eng. Chem., 1922, **14**, 937—940.

Metals accelerate the production of rancidity in ard, corn (maize) oil, and cottonseed oil in the presence of air or oxygen, but the action of the metal is independent of the corrosive action of the at upon it. Light is necessary for the development of rancidity in fats exposed to air and not in contact with metals, but not when the fat is in contact with metals. When air is excluded, *e.g.*, by filling the containing vessel completely with the oil or fat, there is no development of rancidity, even when fats are in contact with metals, but rancidity develops n an atmosphere of carbon dioxide. One experiment indicated that moisture has little influence. Fats stored, with and without contact with metals, n an atmosphere of oxygen developed rancidity earlier, and the development of rancidity progressed more rapidly than when stored in air. The catalytic action of metals can be prevented by coating them with bakelite, and a copper strip so treated remained unattacked at the end of several weeks when immersed in lard exposed to the air at 0° C.—A. J. H.

Patents.

Fats; Manufacture of nutritious ——. G. Schicht A.-G., and A. Grün. E.P. 160,840, 31.3.21. Conv., 1.4.20.

Neutral fats, alone or mixed with free fatty acids, re converted into mono- and di-glycerides by heating with glycerol and are then converted into mixed glycerides by esterification with free fatty acids. They are finally refined in the manner ustomary for edible fats. The process may be xpedited by using catalysts such as metallic tin r zinc. Mixed glycerides containing butyric and proic acids, such as occur in butter, can be manufactured in this way and cholesterol, lecithin, atural colouring matters, and vitamins may be dded.—H. C. R.

Fat resembling butter; Manufacture of ——. Oelwerke Germania G.m.b.H. G.P. 357,877, 27.4.20.

mixture of fatty acids of similar constitution to ose present in butter is treated with glycerin, and e mixture of glycerides obtained is purified. For ample, a stream of a non-reacting gas is passed for veral hours through a mixture of 193 pts. of fatty ids from tallow, 7 pts. of crude butyric acid, 4 pts. of glycerin, and a catalyst, agitated on a ater-bath.—L. A. C.

ls and fats; Process for the purification of ——. N. Goslings. E.P. 172,923, 23.6.21. Conv., 14.12.20. Addn. to 167,462–3 (J., 1922, 769 A).

me or other insoluble soaps of solid fatty acids, as ll as soluble salts, and bases, such as alkaline-rth or other metal oxides or hydroxides, which m insoluble soaps with fatty acids, are added to s and fats in the process described in the chief tent. For example, 85 kg. of a suspension of lime in water, containing 70% of calcium oxide, and 25 kg. of sodium chloride are added gradually, at the ordinary temperature, to 10,000 kg. of raw rapeseed oil containing 5% of free fatty acids. The mixture is agitated until the free fatty acids are neutralised, and then heated, under reduced pressure if desired, to expel the water. The temperature is then raised slowly to 90° C., 500 kg. of powdered lime-coconut oil soap is added, and solid material is separated by filtration or centrifuging.—L. A. C.

Extraction of oils, fats, waxes, and the like; Method of and plant for ——. J. A. Reavell, and Kestner Evaporator and Engineering Co., Ltd. E.P. 186,642, 1.4.21.

The solvent is heated, passed to the extractor, and then circulated through the heater and extractor until the whole mass reaches the desired temperature. The effluent (oil, moisture, and solvent) is then passed through a vaporiser and the vapours and oil particles from this are passed through a separator, the effluent being afterwards passed through a distiller and through another separator where the final separation of the oil takes place. The vapours from the latter separator are passed through a condenser and the condensed liquid, after passing through a separator to remove the water, is passed back to the solvent storage tank. The Kestner horizontal tubular evaporator (E.P. 122,500; J., 1919, 163 A) can function as heater, circulator, vaporiser, and distiller.—H. C. R.

Extraction of oil from oil-containing material; Apparatus for ——. Schlotterhose und Co. G.P. 357,693, 18.7.20. Addn. to 347,394 (J., 1922, 261 A).

In the apparatus described in the chief patent, a larger filtering surface is provided, and stoppage of the process owing to defects in the filtering surface is avoided by separating the suction and filtering apparatus into a number of separate chambers, which can be operated together or independently of one another.—L. A. C.

Triglycerides; Process for hydrolysing —— *into fatty acids and glycerin.* R. Tern. G.P. 357,695, 8.2.21.

Triglycerides are hydrolysed by subjecting them, in the presence of water, to the action of ultra-violet rays at the ordinary temperature and pressure.
—L. A. C.

Fatty acids; Process of manufacturing —— [*from montan wax*]. W. Mathesius. G.P. 358,402, 31.1.18. Addn. to 350,621 (J., 1922, 728 A).

Montan wax is substituted for the hydrocarbons specified in the previous patent. The resulting fatty acids may be employed in soap manufacture.
—J. S. G. T.

Wax and resin colloids; Preparation of neutral, solid ——. Chem. Werkstätten G.m.b.H. G.P. 357,378, 8.2.21.

Heated wax or resin is agitated, with or without application of pressure, with concentrated solutions of, *e.g.*, alkali lactates, until a homogeneous mixture is obtained. The product is stirred or kneaded while hot with oils and fats, such as marine animal oil or rape-seed oil, and other organic solvents, while other organic material, such as pitch, anthracene residues, or paraffins, is subsequently added to the mixture. The products are suitable for use as lubricants, pastes, and ointments.—L. A. C.

Detergent and bleaching agent; Manufacture of a ——. Deutsche Gold- und Silber-Scheideanstalt vorm. Roessler. G.P. (A) 357,956, 13.3.19, (B) 357,957, 17.6.19.

(A) A detergent and bleaching agent is prepared by mixing sodium peroxide and a little more than the equivalent weight of sodium bicarbonate with waterglass of, *e.g.*, 30° B. (sp. gr. 1·263), with or without the addition of protective agents, such as magnesium or calcium silicate. After setting, the mixture is ground and dried. (B) The oxygen content of the above product is increased by the addition of hydrogen peroxide during any stage of the process of manufacture.—L. A. C.

Fire-extinguishing and washing materials; Process for manufacturing ——. Plauson's Forschungsinstitut G.m.b.H. G.P. 358,572, 27.10.21.

Chlorinated hydrocarbons are dispersed in water in a Plauson colloid mill or other high-speed impact mill, with the addition, if desired, of a small amount of protein, glue, gum, soap, or other protective colloid, and organic substances affecting the mutual solubility of the chlorinated hydrocarbon and water. Thus, a colloidal suspension of 1 pt. of chlorinated hydrocarbon in 3 pts. of water is equally effective as a detergent as the pure chlorinated substance, and is moreover less volatile. —J. S. G. T.

Viscous oily compositions; Manufacture of —— and treatment of waxes for use therein. Plauson's (Parent Co.), Ltd. From H. Plauson. E.P. 186,950, 13.4.21.

See G.P. 347,084 of 1920; J., 1922, 300 A.

Lime sludge; Process of separating saponaceous matter from ——. P. Krebitz. E.P. 186,960, 3.6.21.

See G.P. 355,492 of 1920; J., 1922, 770 A.

Pea-nuts, ground nuts, etc.; Preservation [by compression in bulk] and/or transportation of ——. A. W. MacIlwaine. E.P. 187,257, 22.4.21.

XIII.—PAINTS; PIGMENTS; VARNISHES RESINS.

Lithopone; Present knowledge on ——. E. Maass and R. Kempf. Z. angew. Chem., 1922, 35, 609—611.

The faults to which lithopone are subject when used as a pigment in exterior coatings are examined and the various hypotheses usually advanced in explanation criticised. All of the hypotheses purporting to account for the inferior behaviour of this pigment on weathering appear to be open to criticism. In certain patented processes designed to render lithopone fast to light, the photosensitiveness is attributed to the presence of chlorides from the materials employed in its manufacture. —A. de W.

Scheele's green; Composition of ——. G. Bornemann. Z. anorg. Chem., 1922, 124, 36—38.

The author finds that Scheele's green is not acid copper ortho-arsenite, $CuHAsO_3$, but a neutral arsenite, $3CuAs_2O_4,xH_2O$. The composition was found to vary with the method of preparation, the product being richer in copper oxide the larger the excess of alkali employed.—W. T.

Fineness and bulk of pigments. H. A. Gardner, H. Parks, and N. Pihlblad. Circ. 143, Paint Manufacturers' Assoc. U.S., April, 1922. 72 pp.

A standardised procedure for the determination of the proportion of particles of a pigment or paint retained on a standard screen of 325 meshes to the inch has been worked out. The wire screen, which is conveniently of 3 in. diam., is tared to the nearest mg., wetted on both sides with a liquid which "wets" the pigment under examination, and a weighed quantity of the sample (2—10 g.) transferred to the screen. If the pigment is wetted with difficulty by water, it may be previously wetted with a liquid with which water is miscible, *e.g.*, alcohol or alternatively other washing liquids, *e.g.*, turpentine etc., may be used. The screen containing the pigment is then held under a tap delivering 300—500 c.c. of liquid per min., a soft camel-hair brush being used to assist the operation of screening. After the majority of the finely-divided portion of the pigment has passed through the screen, the latter is immersed to a depth of 0·5-in. in an 8-in. porcelain dish containing 250 c.c. of the washing liquid, the pigment remaining on the screen being then brushed with a soft 1-in. camel-hair brush at the rate of two strokes per sec. during two periods of 10 secs. each. The screen is then raised from the dish after each 10-sec. period to let the liquid run through, and the liquid in the dish changed after every two brushing periods. This is continued until typewritten letters can be read through an 8 cm. layer of the wash liquid. Finally the pigment adhering to the brush is transferred to the screen, and the latter and its contents washed with, *e.g.*, alcohol and ether, dried, and weighed. Notes are appended as to methods of guarding against possible sources of error, *e.g.*, distinguishing between secondary aggregates and coarse primary particles. Photomicrographs of screened coarse particles from typical pigments mounted on a talking machine disc (J., 1920, 342 A) are given. The method previously published (J., 1920, 356 A) is elaborated in extenso, and sketches are given of the apparatus recommended for the determination of specific gravities of pigments under diminished pressure. The paper includes tables giving relationships between sp. gr., weights per solid gallon, and gallons (U.S. standard gallon=0·833 Imp. gallon) per unit lb. of various paint media, solvents, and dry pigments, and a chart correlating these figures with specific gravities from 0·7 to 9·7. These data, together with the proportion of residue left on a 325-mesh screen, using a specific washing liquid, are given for a very large number of pigments and fillers of U.S. proprietary manufacture, together with such information regarding the sample as was voluntarily submitted by the maker.—A. de W.

Paints; Miscellaneous exposure tests on ——. H. A. Gardner. Circ. 153, Paint Manufacturers' Assoc. U.S., June, 1922. 32 pp.

Examination of both sprayed and hand-brushed paint work on the walls and roof of a building after exposure for 32 months pointed to slightly more uniformity of application in the case of the hand-brushed work in places where the surface was rough or sunken. Examination of various wood and metal test panels after exposure for 3 years on Young's Pier at Atlantic City showed the remarkable protective qualities of paints made on a basis of American vermilion (basic lead chromate), no fading, chalking, or carbonation being apparent. As a medium for metallic aluminium and metallic zinc paints boiled linseed oil is to be preferred to spar varnish, which in turn is superior to collodion solutions. In paints containing red lead, a protective covering coat or addition of a pigment fast to light, *e.g.*, iron oxide, is advisable on account of the bleaching which red lead suffers on exposure. An inspection, after exposure for 11 months, of white paints having a basis of antimony oxide, alone and mixed with white lead, zinc oxide, or barium sulphate, together with titanium oxide mixed with zinc oxide, and also other mixed pigments, showed the superiority of zinc oxide over white lead as an ingredient of both antimony oxide and titanium oxide paints. Titanium oxide, when present in proportions of 10% and 15% in a pigment consisting otherwise of inert fillers, showed poor results after weathering for 20 months, but when present in proportions of 6% and 9%, together with 40% of zinc oxide, withstood exposure well under the same conditions; the addition of whiting as a constituent of the inert fillers was, however, inadvisable. In a series of tests in which white pine panels covered with three coats of paints consisting of antimony oxide alone and with various other pigments were exposed for 16 months, an optimum result was secured when the antimony oxide was present in about equal amount to both barytes and zinc oxide, the chalking tendency and slow drying of the antimony oxide being partly counterbalanced by the zinc oxide. The same mixture also showed the best behaviour on storage, antimony oxide alone having a tendency to become stringy. Discoloration of antimony oxide paints to a salmon-pink cast occurs when they are exposed to hydrogen sulphide. A preliminary exposure test in a sulphur-producing region in Texas of three paints in two of which the pigment consisted of leaded zinc oxide and lithopone and in the third "titanox" (titanium oxide and barium sulphate) and zinc oxide, showed the great superiority of the last-named paint in maintaining its purity of colour.—A. de W.

Vanadium as a drier for linseed oil; Experiments with ——. H. A. Gardner. Circ. 149, Paint Manufacturers' Assoc., U.S., April, 1922. 7 pp.

Confirming the results obtained by Rhodes and Chen (J., 1922, 334 A), the author finds that linseed oil siccatised with vanadium becomes dark brown in colour. Whilst the cost of vanadium drier is greater han that of cobalt drier, the latter is more efficacious and gives products paler in colour. Although vanadium rosinate cannot be prepared by heating ammonium metavanadate with rosin, the fused inoleate can be obtained by heating ammonium natavanadate to 300° C. with raw linseed oil to which has been added 10% of linseed oil fatty acids. The time of drying of linseed oil siccatised with vanadium is not markedly different from that of oil siccatised with other known driers.—A. de W.

Fossil resins; Esterification of —— and production of neutral varnishes therefrom. H. A. Gardner and P. C. Holdt. Circ. 151, Paint Manufacturers' Assoc. U.S., May, 1922. 10 pp.

Experiments carried out on a laboratory scale to determine the conditions for esterification of the highly acid gum-resins, Congo, Pontianak, and Manila to substantially neutral esters, showed that care should be taken completely to "crack" or "run" the resin before addition of glycerin for esterification, or polymerisation of the product to an infusible mass results. Copper and aluminium act as catalysts in the polymerisation, which, however, is entirely inhibited when "running" has been thorough. The authors have determined the times and temperatures necessary to accomplish complete "running" on 100-g. batches of the three gum-resins named and recommend the use of 6—8% of glycerin on the weight of the "run" gum-resin, a temperature of 292°—295° C. being maintained for such time as may be necessary to secure the desired degree of neutralisation compatible with maintenance of colour. Addition of about 0·3% of zinc dust either before or after "running" reduces the time necessary for subsequent esterification. Comparative trials of varnishes made with normally "run" gum-resin and with an esterified gum-resin showed the absence of any tendency of the latter to cause "livering" with zinc oxide over a period of 8 months in storage, whilst tests of the esterified product against caustic soda solutions indicated a great degree of resistance to alkali.—A. de W.

Resin acids of the coniferæ. V. Nitrosochloride, nitrosite and nitrosate of pinabietic acid and abietic acid (Levy). Constitution of abietic acid and abietene. O. Aschan. Ber., 1922, 55, 2944—2959.

Pinabietic acid obtained from pine oil bears a very close resemblance to Levy's abietic acid obtained from American colophony. The nitrosochlorides, nitrosites, and nitrosates of the two compounds appear to be identical, so that they are to be regarded as structurally identical but possibly stereoisomeric with one another, since certain (unpublished) differences are exhibited in their optical behaviour. The tetrahydroxy acid described by Levy (J., 1906, 1057; 1907, 1151; 1910, 33) and characteristised by its well defined individuality and high melting point, appears to be derived from associated silvinic acid since the authors have not obtained it from either abietic or pinabietic acids. Levy's abietene and Virtanen's pinabietene (*cf.* J., 1921, 594 A) must be regarded as structurally identical 7.13-dimethyl-2-isopropyl-5.6.7.8.9.10.13.14-octahydrophenanthrenes. (*Cf.* J.C.S., Dec.)
—H. W.

Solvents; Evaporation of ——. H. Wolff and C. Dorn. Farben-Zeit., 1922, 28, 31—33.

The losses in weight sustained by weighed quantities of various solvents contained in Petri dishes or spotted on filter papers, when exposed to the air at ordinary temperatures, showed that no connexion exists between the rate of evaporation and the boiling-point. Petroleum hydrocarbons appear in general to volatilise more rapidly than benzene hydrocarbons of the same boiling-points. The presence of dissolved oil or resin in a solvent retards the volatilisation of the latter; two bends indicating retardation appear in the curve showing loss in weight with time, one at the commencement of the process and one towards the end. For one and the same solvent, the rate of evaporation varies with the different resins present as solutes.

Patents.

Pigment and method of producing same. P. Fireman, Assr. to Magnetic Pigment Co. U.S.P. 1,392,925–7, 11.10.21. Appl., 22.6.20.

The pigments are prepared by oxidation of freshly precipitated ferrous hydroxide under varying conditions. *Examples:* (A) A solution of ferrous chloride of sp. gr. 1·06—1·09 is treated with a quantity of calcium hydroxide sufficient to precipitate 75—85% of the iron, and the mixture is treated with air and steam at a temperature not above 100° F. (38° C.) until the ratio of ferrous to ferric iron is about 1:0·5. The mixture is then heated to boiling by increasing the amount of steam, and oxidation continued until a lemon-yellow product is obtained. (B) Ferrous chloride solution of sp. gr. 1·07—1·105 is rendered alkaline with sodium carbonate and treated with air and steam at a temperature not exceeding 110° F. (43° C.) at first, but gradually rising to the boiling point. The product, on drying, is a bright brown pigment. (C) Ferrous chloride solution of sp. gr. 1·05 is treated with insufficient calcium hydroxide to precipitate the whole of the iron, and air and steam are introduced, oxidation being effected at a temperature rising gradually from 105° F. (40·5° C.) to 130° F. (54° C.). Pigments of varying shades of tan are obtained by varying the temperature between the limits specified.

Colour lakes; Preparation of ——. P. Kraïs and H. Wislicenus. G.P. 358,047, 8.8.20.

"Sprouted" alumina, prepared by exposing aluminium which has been treated with mercury salts to the action of moist air, is employed for the preparation of colour lakes, the alumina, *e.g.*, being agitated with solutions of dyestuffs.—L. A. C.

Chambers for collecting lampblack; Process for transferring heat for preventing deposition of oil and water in ——. F. und K. Meiser. G.P. 358,048, 2.7.21.

A limited circulation of gas is maintained by means of fans or natural draught through a series of chambers for the deposition of lampblack, the hot gases from the first chamber being led into the last chamber to expel water and oil deposited therein. The gases leaving the last chamber pass into a cooler in which oil and water vapour are condensed. —L. A. C.

Condensation products of cresols and xylenols; Manufacture of resinous ——. Chem. Werke Grenzach A.-G. G.P. 357,756, 8.2.20.

Compounds such as *o*-cresol, crude cresol containing phenol, or *m*-xylenol, are treated with air or oxygen in the presence or absence of catalysts, *e.g.*, with moist air at 150°—170° C. for 10—12 hrs. in the presence of manganese dioxide or ferric chloride. Unchanged phenols are separated by distillation in a current of steam. The products are either soft, or hard and brittle, and of a dark brown or black colour, according to the time and temperature of treatment, and soft products can be hardened and rendered brittle by further heating.—L. A. C.

Condensation products of phenolcarboxylic acids or their derivatives and aldehydes; Manufacture of ——. Farbw. vorm. Meister, Lucius, und Brüning. G.P. 357,757, 24.1.20, 357,758 and 358,401, 5.3.20. Addns. to 339,495 (J., 1922, 639 A).

Aromatic hydroxycarboxylic acids in alkaline solution, or aromatic alkoxycarboxylic acids, are treated with formaldehyde, or substances capable of yielding it, at atmospheric or moderately high temperatures, or are treated with aldehydes at high temperatures under pressure. Examples are given of the preparation of resinous products by the action of formaldehyde on a mixture of *o*- and *p*-hydroxybenzoic acids in alkaline solution at the usual temperature, on *m*-cresotinic acid in alkaline solution at 30° C., on *o*-methoxybenzoic acid in the presence of concentrated sulphuric acid at 100 ° C., on *o*-ethoxybenzoic acid at 140°—150° C. under pressure, and on salicylic acid at 130° C. under pressure; by the action of paraformaldehyde on 2-ethoxynaphthalene-3-carboxylic acid at 100° C. in the presence of acetic acid and concentrated hydrochloric acid; by the action of ethylal on a mixture of *o*-, *m*-, and *p*-cresotinic acids at 130° C. under pressure; and by the action of benzaldehyde on 2-hydroxynaphthalene-3-carboxylic acid at 130°—140° C. under pressure in the presence of zinc chloride.—L. A. C.

Condensation products of phenols and aldehydes; Manufacture of ——. Felten und Guilleaume Carlswerk A.-G. G.P. 358,195, 3.8.19.

Insoluble and infusible condensation products, especially suitable for the manufacture of electrical insulators, are prepared by the action of aldehydes, *e.g.*, formaldehyde or its polymerisation products, or furfural, on phenols in the presence of phenols which contain one or more basic groups in addition to the hydroxyl group or groups, *e.g.*, aminophenols, methylamino or ethylamino derivatives of phenol, cresol, or naphthol, hydroxyquinoline, or hydroxydiphenylamine.—L. A. C.

Condensation products of phenol alkyl ethers and formaldehyde; Manufacture of resinous ——. Akt.-Ges. für Anilin-Fabr., Assees. of (A) C. Marx, O. Siebert, and H. Wesche, (B) C. Marx and H. Wesche. G.P. (A) 358,399, 25.11.20, (B) 358,400, 8.12.20.

Resinous products suitable, *e.g.*, for the manufacture of varnishes, are prepared by treating (A) phenol alkyl ethers substituted in the meta position to the alkoxy group by an alkyl or alkoxy group, *e.g.*, *m*-cresol methyl ether or resorcinol diethyl ether, or (B) *ar*-tetrahydronaphthol alkyl ethers, with formaldehyde, or compounds capable of yielding the same, in the presence of acids. *ar*-Tetrahydronaphthol alkyl ethers are prepared by sulphonating tetrahydronaphthalene, fusing the product with alkalis, and treating the product with alkylating agents.—L. A. C.

Oil of turpentine; Improving the odour of — obtained, e.g., in the manufacture of sulphate-cellulose. A. W. Arldt. G.P. 358,050, 7.3.17.

Mercaptans are removed from crude oil of turpentine, obtained, *e.g.*, in the manufacture of sulphate-cellulose, by treating the oil with hydrogen at 100°—120° C., under normal or increased pressure, in the presence of alkaline solutions of lead oxide, zinc oxide, or other metal oxides, or iron or other metals. —L. A. C.

Pencil drawings on paper; Fixing and blackening ——. A. Grünert. G.P. 358,584, 13.10.21. Addn. to 317,444 (J., 1920, 377 A).

In the process described in the chief patent, the upper roller or plate is removed slightly from the surface of the paper, the intermediate space being filled with the electrolyte.—L. A. C.

Dispersoids, colloid powder and [plastic] masses therefrom; Manufacture of ——. H. Plauson, Assr. to D. R. Rotman. U.S.P. 1,392,849, 4.10. Appl., 8.2.21.

See E.P. 156,142 of 1920; J., 1922, 381 A.

Resin colloids. G.P. 357,378. *See* XII.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Latex of Hevea Brasiliensis; Function of calciu chloride in coagulation of ——. G. Verne Comptes rend., 1922, 175, 719—721.

The addition of calcium chloride solution to lat of *H. Brasiliensis* accelerates the coagulation a increases the yield of rubber, the latter dependi to some extent on the amount of added chlorid The rubber thus obtained contains calcium, pho phate, and chloride in percentages which vary the amount of solution added. The author conclud that the calcium reacts with the soluble phosphat of the latex forming calcium phosphate which incorporated in the rubber and the resulting chlorid causes protein coagulation; further, the normal c agulation is more complete. The increase in weigh of product is due to all three factors.—H. J. E.

Stearic acid in latex from Ficus fuvla, Reinw. A. J Ultée. Bull. Jardin Botan. Buitenzorg, 1922, 105—106. Chem. Zentr., 1922, 93, III., 1055.

Of the coagulated latex only 7·7% was insoluble i alcohol, and extraction of this residue with benzen yielded 1·1% of rubber (calculated on the origin weight). The alcoholic extract from 12 g. whe cooled deposited 8·35 g. of wax, m.p. 52°—58° C. which on saponification gave potassium stearate an a phytosterol. The wax is not identical with th from *Ficus elastica*.—D. F. T.

Rubber vulcanisation; Studies in ——. Relation between chemical and physical state of cure of rubber vulcanised in the presence of certain organic accelerators. N. A. Shepard and S. Krall. J. Ind. Eng. Chem., 1922, **14**, 951—956.

As was already realised by Weber in 1902, products obtained by the vulcanisation of one and the same batch of crude rubber to the same coefficient may possess different physical constants. The physical state of the vulcanised rubber is now recognised as of main significance from the point of view of performance in service, whereas the chemical degree of vulcanisation has the more important bearing on the stability of the physical condition. When organic accelerators are used the relationship between the physical properties and the vulcanisation coefficient becomes strikingly irregular (*cf.* Cranor, J., 1920, 73 A). Mixtures containing rubber (48 pts.), zinc oxide (48), and sulphur (3) with hexamethylenetetramine (0·5 pt.), aldehyde-ammonia (0·75), thiocarbanilide (1·5), and *p*-nitrosodimethylaniline (0·25) respectively as accelerator, when vulcanised for 60 mins. at 141·7° C. (287° F.) gave almost identical stress-strain curves (elongation about 400% at 1070 lb. per sq. inch). In determining the corresponding coefficients of vulcanisation, disturbing factors were eliminated as far as possible (*cf.* Kelly, J., 1922, 301 A); the resulting values were 0·87, 0·98, 1·38, 1·03 respectively.—D. F. T.

Patents.

Vulcanisable compositions. W. Frost, and H. Frost and Co. E.P. 186,709, 5.7.21.

An adhesive and plastic rubber mixture for repair purposes consists of an ordinary vulcanisable mixture softened by the addition of about 30—40% of carbon tetrachloride or other suitable solvent. —D. F. T.

Rubber; Conversion of natural or artificial —— into other varieties of rubber or into material resembling gutta-percha. Siemens und Halske A.-G. G.P. 354,344, 23.1.20.

Dispersions of hydrohalides or halogen derivatives of rubber in chloroform or ethylene chloride are reduced by treatment with zinc or other metals, and the product is washed with water or dilute acid. The product is more or less viscous according to the method of treatment, and resembles gutta-percha if ethylene chloride is used as dispersion agent. —L. A. C.

Insulating material. G.P. 357,665. *See* XI.

XV.—LEATHER; BONE; HORN; GLUE.

Humidity equilibria. Wilson and Fuwa. *See* I.

Pseudo-extraction. Charitschkov. *See* I.

Patents.

Tannery waste liquor containing sulphides; Purification of ——. Adler und Oppenheimer, Lederfabr., A.-G. G.P. 358,105, 3.2.14.

Hydrogen sulphide liberated by treating tannery waste liquors with acids is burnt and the sulphur dioxide liberated thereby is led into the liquor to decompose residual hydrogen sulphide with precipitation of sulphur. Dissolved or emulsified material derived from the hides is precipitated simultaneously, and a clear liquor free from objectionable odour is obtained.—L. A. C.

Products insoluble in water; Manufacture of —— from glycerin and albumins. G. Diesser. G.P. 358,540, 1.8.15.

Egg- or blood-albumin is ground with glycerin, yielding liquid products which rapidly harden either alone or on treatment with formaldehyde or potassium bichromate. The products are suitable for making moulded articles, for use as an adhesive for cellulose, waste leather, or cork, or for adding to rubber.—L. A. C.

XVI.—SOILS; FERTILISERS.

Soils; Field moisture capacity and wilting point of ——. W. L. Powers. Soil Sci., 1922, **14**, 159—165.

The wilting point of different crops varies more than is usually suspected. The variation among different crops is greater on a heavy than on a light soil. From irrigation studies it is shown that a heavy soil may retain as much as two inches of utilisable water per acre-foot depth, peat can retain 3—4 in., and a coarse sand only ½ in. The bearing of these points on the practice of irrigation is discussed.—A. G. P.

Sulphides; Occurrence of —— in Minnesota peat soils. C. O. Rost. Soil Sci., 1922, **14**, 167—174.

Examination of a large number of Minnesota peat soils showed that the presence of sulphides at all depths is general. Usually there was more sulphide in the lower layer of peat than in the muck substratum. The reaction of both peat and muck depended more on the conditions permitting the oxidation of sulphides to sulphuric acid than on the actual amount of sulphide present. The lower peat layers contained sulphide equivalent to 0·06—0·16% H_2S and the muck substrata 0·002—0·013%. —A. G. P.

Iron pyrites; Oxidation of —— by sulphur-oxidising [soil] organisms, and their use for making mineral phosphates available. W. Rudolf. Soil Sci., 1922, **14**, 135—146.

From studies of pyrites-soil composts inoculated with sulphur-oxidising organisms, it was shown that the pyrites can be oxidised to sulphate. In the presence of small quantities of sulphur the process was considerably accelerated. The solution of rock phosphates in soil-sulphur-phosphate composts proceeded normally in the presence of pyrites; when ammonium sulphate was added, the production of available phosphoric acid was considerably increased by pyrites, which appeared to have some catalytic action. Composts of pyrites-sulphur-phosphate were not benefited by aeration unless ammonium sulphate was present. The addition of sulphurous acid to the composts produced merely a sterilising action.—A. G. P.

Fungi in soil; Growth of ——. S. A. Waksman. Soil Sci., 1922, **14**, 153—157.

The gelatin plate method of studying fungi in soil is inadequate, since it does not give a true representation in species or in numbers of the soil flora. Two acid media are described in which fungi but not bacteria or actinomyctes will develop. (1) 25 g. of agar is dissolved in a solution prepared by beating 60 g. of raisins with 1000 c.c. of tap water for 1 hr., the reaction is adjusted to p_H 4·0, and the liquid filtered and sterilised. (2) Sufficient $N/1$ sulphuric or phosphoric acid is added to a mixture of 10 g. of dextrose, 5 g. of peptone, 1 g. KH_2PO_4, 0·5 g. $MgSO_4$ and 1000 c.c. of water to give a p_H value 3·6—3·8. 25 g. of agar is dissolved in the solution, which is then filtered and sterilised. A definite correlation between the number of fungi present in a soil, and its treatment and reaction has been established.—A. G. P.

Fungi and actinomycetes in soil; Microscopical method for demonstrating ——. H. J. Conn. Soil Sci., 1922, 14, 149—151.

A small portion of soil (10 mg. or less) is placed on a microscope slide, and moistened with a few drops of water. One drop of methylene blue solution is added and the whole covered with a slip, sand grains being removed. The mount should appear distinctly blue to the naked eye. By thus obviating the drying of the mount, actinomycete filaments and mycelium are not destroyed and can be easily observed. By this technique fragments of mycelium were found in many soils, though not in great quantity; their presence was more frequent in soils containing large quantities of undecomposed organic matter.—A. G. P.

Denitrification with formates. Influence of the cation. J. Groenewege. Biedermann's Zentr., 1922, 51, 219—220.

Denitrification with *Bact. denitroformicicum* (n. sp.) does not take place where calcium formate is the exclusive source of carbon in culture solutions containing potassium monohydrogen phosphate owing to the formation of calcium phosphate and free formic acid. If the culture solution is maintained neutral or slightly alkaline, denitrification only takes place on aeration. If, however, the calcium formate is replaced by potassium or sodium formate, denitrification takes place even under anaerobic conditions.—G. W. R.

Arsenic; Some relations of —— *to plant growth.* J. Stewart. Soil Sci., 1922, 14, 111—118.

The solubility of lead arsenate in water is considerably increased by the addition of salts commonly found in the soil solution. The most effective are acid salts and those producing an alkaline solution. The solubility in soils of lead arsenate is roughly proportional to the amount of soluble salts in the soil. (*Cf.* J.C.S., Dec.)
—A. G. P.

Arsenic; Some relations of —— *to plant growth. II.* J. Stewart and E. S. Smith. Soil Sci., 1922, 14, 119—136.

Distinct stimulative effects were observed in plants grown in soil treated with sodium arsenate. The accumulation in soils of arsenic from sprays, may be beneficial rather than injurious, since the amount of soluble arsenic is limited by the solubility of lead arsenate, which is normally below the toxic point.
—A. G. P.

Protein content of grain; Differences effected in the —— *by applications of nitrogen made at different growing periods of the plant.* W. F. Gericke. Soil Sci., 1922, 14, 103—109.

The protein content of wheat and other grains and the hardness of the grain are not entirely hereditary characteristics, but to a large extent affected by environment. The addition of sodium nitrate to soils carrying spring wheat, increased the protein content of the matured grain to an extent varying according to the period elapsing between the sowing of the seed and the time of adding the fertiliser. (*Cf.*, J.C.S., Dec.)—A. G. P.

Urea and hippuric acid as nutrient materials for plants. T. Bokorny. Biochem. Zeits., 1922, 132, 197—209.

In higher strengths than 0·09% hippuric acid is toxic to plant cells, urea at 1·0% being harmless.
—H. K.

Patent.

Calcium cyanamide; Method of granulating ——. Stockholms Superfosfat Fabriks Aktiebolag. E.P. 168,070, 22.8.21. Conv., 21.8.20.

Calcium cyanamide is ground and kneaded in a steam-jacketed worm conveyor under the action of a spray of warm dilute nitric acid, 25% of 5—20% acid being used on the weight of calcium cyanamide. The mass is then fed into steam-jacketed rotating cylinders wherein it meets a counter current of hot air. The granules so produced do not disintegrate on storage.—C. I.

XVII.—SUGARS; STARCHES; GUMS.

Sugarhouse [evaporator] syrups; Precipitate formed in —— *[after clarification].* J. F. Brewster and W. G. Raines, jun. J. Ind. Eng. Chem., 1922, 14, 946—947.

Juice clarified by treatment with kieselguhr and decolorising carbon (*cf.* Zerban, J., 1921, 21 A) and then concentrated to a density of about 30° B. (sp gr. 1·262) was found to contain a precipitate consisting of about 75% of mineral matter, mainly SiO_2, CaO, and SO_3. Small-scale experiments, using different methods of clarification, indicated that the precipitate is due to a greater or less extent to the use of juice derived from cane to which a considerable amount of soil still adhered, the amount of precipitate obtained from the juice of washed cane being often much less. In the case of juice clarified by the defecation or sulphitation processes, in addition to the cause suggested, the formation of the precipitate may be due to the chemicals used, which partly enter into solution; and to substances originally present in the juice, which are precipitated on concentration.—J. P. O.

Sugar purity determinations. W. D. Horne. J. Ind. Eng. Chem., 1922, 14, 944—945.

The apparent purity may be rapidly ascertained by determining the sucrose by direct polarisation after clarifying with Horne's dry lead subacetate, and the dry substance from a density reading, using a special Brix hydrometer provided with a thermometer, against the scale of which is placed a table giving temperature correction readings. Having these two data, the purity may then be immediately read from a table mounted on movable rolls easily exposing the desired portion.—J. P. O.

Glucose; Determination of the p_H value as a substitute for the candy test as an indication of commercial ——. O. A. Sjostrom. J. Ind. Eng. Chem., 1922, 14, 941—943.

Determination of the p_H value by the colorimetric method using methyl red gives a more reliable indication of the acidity available for inversion of commercial glucose destined for use in confectionery manufacture than the results given by the "candy test," in which the amount of invert sugar formed on heating the samples with sucrose and water under certain conditions is determined. Using samples of commercial glucose diluted to 22° B. (sp. gr. 1·18), it was found that the extreme limit of safety is represented by p_H 4·3.—J. P. O.

Tetralævoglucosan and tetraglucosan. H. Pringsheim and K. Schmalz. Ber., 1922, 55, 3001—3007.

Tetralævoglucosan is readily converted by acetic anhydride in the presence of zinc chloride into the dodeca-acetate, an amorphous hygroscopic substance, $[\alpha]_D^{20} = +69{\cdot}59°$ in glacial acetic acid solution; it is completely methylated by two treatments with sodium hydroxide and methyl sulphate at 70° C., yielding dodecamethyl-lævoglucosan, which is hydrolysed by boiling dilute sulphuric acid (5%) to tetramethylglucose and a dimethylglucose. Under similar conditions, tetraglucosan yields a dodeca-acetate, $[\alpha]_D^{20} = +70{\cdot}82°$ when dissolved in glacial acetic acid, and dodecamethyltetraglucosan. The behaviour of the polymerised anhydro-sugars is thus sharply differentiated from that of the polyamyloses hich cannot be completely methylated and suffer epolymerisation when acetylated with acetic anydride in the presence of zinc chloride. (*Cf.* J.C.S., lec.)—H. W.

mylodextrin; Oxidation of ——. W. Syniewski. Roczniki Chem., 1922, 2, 83—94.

EXTRIN (from starch) when oxidised by means of romine in the presence of barium carbonate (to revent the hydrolysis of the molecule) yielded a hite non-crystalline product with an acid reaction nd rotatory power $[\alpha]_D^{20}$=191·09°. Its reducing ower was 23·24% of that of maltose. A solution of the roduct reduced alkaline silver solution and gave he "Molisch" reaction with α-naphthol, but the olour was not violet, as with starch and the sugars, ut carmine-red. A concentrated solution of the ubstance gave a beautiful reddish colour on warmng with hydroxylamine hydrochloride and potasium hydroxide. Analysis gave C 42·71%, H 5·33%. The product is an acid, the barium salt containing 5·06% BaO; the author calls it amylodextrinic cid. Amylodextrin is considered to have the ormula $C_{216}H_{372}O_{186}$ and to be composed of twelve naltose residues connected together by the carbonyl roups, leaving only the CH_2OH groups free. The H_2OH groups are converted into carboxyl groups y oxidation, so that the acid oxidation product vill have the formula, $C_{216}H_{348}O_{198}$, which is in good greement with the results of analysis.—W. T.

PATENT.

Extraction of sugar. E.P. 186,756. *See* XIXA.

XVIII.—FERMENTATION INDUSTRIES.

Diastatic power; Determination of ——. W. Windisch, W. Dietrich, and P. Kolbach. Woch. Brau., 1922, 39, 213—214, 219—222, 225—226.

HE divergent values for the diastatic power of a alt obtained by the iodometric method when fferent starches are used depend to some extent variations in the hydrogen-ion concentration and egree of dispersion of the starch solutions. Since e malt extracts obtained from different malts vary t slightly in acidity and since also but little of e extract is used in determining the diastatic ower, the value of p_H for the mixture of starch lution and malt extract depends almost entirely on e acidity of the starch. Samples of soluble starch pplied by different makers gave 2% (on dry atter) solutions varying in p_H from 3·7 to 6·2, the alues after addition of one and the same cold-water alt extract ranging from 4·1 to 6·1 and the umbers obtained for the diastatic power from 126 95 (or for a second malt, from 133 to 95); when, owever, the values of p_H were made equal in all e cases to 4·9 by addition of a buffer solution, the astatic powers found varied only from 124 to 113 31 to 121). That one of the starches gave lower lues for the diastatic power after addition of the uffer solution is due to the fact that the optimum lue of p_H for diastatic action is not 4·9, as stated Adler, but 4·26. Although the activity of diasse is not appreciably less for p_H 5·8, which is the erage value for unboiled wort, than it is for p_H 3, yet adjustment of the hydrogen-ion concentraon may result in increase of the yield of extract the brewery by as much as 2%. This increase is e to the fact that increase of the acidity (to p_H 5) vours the action of the proteolytic enzymes and nce not only renders a greater proportion of the oteins permanently soluble but also renders the arch granules more readily accessible to the action the diastase. The increased acidity also lowers e danger of subsequent protein-turbidity, proces a better "break" of the wort, and improves flavour of the resulting beer. A method of determining diastatic power, in which the iodine used by the starch and the p_H value of the starch solution are taken into account, is described. The same starch must be employed in all cases, Kahlbaum's soluble starch being recommended; the starch solution must be prepared in a definite way and, since the course of the conversion depends on the degree of dispersion, must be used fresh. By addition of a suitable quantity of a buffer solution containing sodium acetate and acetic acid, the p_H of the solution is brought to 4·3±0·1. Details of the procedure and of the method of calculation of the results are given.—T. H. P.

Hydrogen-ion concentration in the brewery. IV. W. Windisch, W. Dietrich, and P. Kolbach. Woch. Brau., 1922, 39, 145—148, 151—153, 157—162, 165—166, 171—172, 177—179, 183—186.

DETAILS are given of a number of investigations, by both the electrometric and the graphic titrimetric methods, of the titration acidity, hydrogen-ion concentration, and buffer effect in worts and beers of various types. The essential result achieved is a proof that indications of sufficient accuracy for practical purposes are obtained if the rectilinear colorimetric titration curve is used in place of the p_H curve.—T. H. P.

Yeast and bacteria; Influence of hydrogen-ion concentration on the development of —— *and on the stability of beer.* M. H. van Laer. Petit J. Brasseur, 1922, Nos. 1193 and 1194. Woch. Brau., 1922, 39, 226—227.

IN Pasteur's solution, containing its nitrogenous nutriment in the form of ammonia, which is assimilable with difficulty by yeast, the latter exhibits its greatest multiplication at p_H 6·8, that is, in the neighbourhood of absolute neutrality; in unhopped and hopped worts prepared from 50% of malt and 50% of raw grain, however, the optimum values of p_H are 4·6 and 6·0 respectively. Hence, the richer the liquid is in nutriment, the higher is the acidity which the yeast is able to withstand. If the culture solution is not perfectly suited to the food requirements of the yeast, the latter is more sensitive towards increase of the alkalinity than towards increase of the acidity. For Frohberg and for distillery yeast the optimum value of p_H is also 4·6, whereas, as might be expected, for lambic yeast it is not higher than 3·8. For two of the most common disease organisms of Belgian beers, namely *Bacillus viscosus bruxelliensis* and *Saccharobacillus*, the optimum values of p_H are respectively 5·5 and 6·8. It is, therefore, evident, that, with unhopped wort, the optimum p_H for the disease organisms is nearer to the natural reaction of the wort than is that for yeast, whilst with hopped wort the reverse is the case. The importance of hopping for the stability of the beer is thus emphasised. Moreover, when Frohberg yeast and *Saccharobacillus* are sown together in hopped wort, the bacteria do not develop appreciably if the p_H of the liquid is below 5·4. Thus, the actual acidity of wort and beer constitutes an important factor in the stability, the highest infection being without results in a sufficiently acid wort.—T. H. P.

Fermentation and yeast; Action of ultraviolet rays on ——. P. Lindner. Woch. Brau., 1922, 39, 166—167.

USING a bottom-fermentation brewery yeast, the author finds that the velocity of fermentation of dextrose is increased by the influence of ultraviolet light to even greater extents than were observed by R. and R. de Fazi (J., 1916, 191) in the case of top-fermentation beer yeast. Thus, fermentation of a solution of 30 g. of dextrose in 300 c.c. of water for 24 hrs. yielded 119 c.c. of carbon dioxide, whereas when the fermenting liquid was exposed to the light of a mercury vapour lamp 2743 c.c. of gas was evolved. The original yeast and that obtained from the latter solution contained little glycogen, which was, however, present in large proportion in the yeast from the solution not exposed to the ultraviolet light. Most of the yeast cells from the radiated solution were in active condition, about 20—30% being dead. Fermentation experiments with wort furnished similar results. Although exposure of yeast to ultraviolet light in a liquid fermenting under ordinary conditions favours the fermentation, exposure of the cells in a shallow layer of liquid to the light for any length of time produces fatal results.—T. H. P.

Yeast; Destruction of lactic acid by ——. O. Fürth and F. Lieben. Biochem. Zeits., 1922, **132**, 165—179.

The disappearance of lactic acid observed on shaking yeast suspensions in a current of oxygen could not be attributed to formation of simple derivatives, such as acetaldehyde, β-hydroxybutyric acid, etc. One half of the carbon of the lost lactic acid does, however, appear as carbon dioxide, the other half possibly being utilised in the building up of tissue.—H. K.

Yeast; Behaviour of some amino-acids towards oxygenated ——. F. Lieben. Biochem. Zeits., 1922, **132**, 180—187.

Unlike lactic acid, amino-acids are not quickly destroyed by oxygenation of their solution in presence of yeast cells.—H. K.

Fermentation; Activators of ——. E. Lindberg. Biochem. Zeits., 1922, **132**, 110—134.

The activating influence of yeast water, yeast co-enzyme, and milk has been determined on washed and unwashed dried yeast and also the influence of abietic acid, amyrin, and cholesterol. The former group accelerate, but the latter group are without action. Pyruvic acid was fermented more rapidly than dextrose, but lactic acid was practically unaffected.—H. K.

Invertase. III. R. Willstätter, J. Graser, and R. Kuhn. Z. physiol. Chem., 1922, **123**, 1—78.

Preparations of autolysed yeast change with age in such a way that the invertase becomes practically completely precipitable by lead acetate. This in combination with the methods previously used—particularly adsorption with aluminium hydroxide, and dialysis—gives a means of obtaining extremely reactive invertase preparations. The precipitation by lead acetate is affected also by other factors, such as substances present in the invertase solution, particularly phosphates. The phosphorus content of these very highly active invertase preparations is very low. The activity of invertase appears to be independent of the other compounds which accompany it, and also independent of the state of aggregation. Incidental impurities are, however, of importance, the very pure preparations being much less stable. Invertase preparations can be protected by the addition of, for example, calcium chloride or yeast gum. Purified invertase has an optimum activity at p_H 4·6.—W. O. K.

Saccharase [invertase] preparations; Phosphorus content of purified ——. H. von Euler and O. Svanberg. Ark. Kem. Min. Geol., 1922, **8**, [12], 1—13.

By estimating the concentration of silver ions electrometrically, the dissociation constants of the silver salts of various nucleic acids and related acids have been determined, and it is concluded that the presence in the invertase molecule of components of the nature of nucleic acids may explain the poisoning of the enzyme by silver salts, as these acids have a strong affinity for silver ions. Purified invertase solutions after dialysis leave an ash which can be completely accounted for by the phosphoric acid present, indicating the absence of any corresponding metal as base. (*Cf.* J.C.S., Dec.)

—W. O. K.

Reductases. I. Some conditions of the activity of starch reductase. I. A. Smorodincev. Z. physiol. Chem., 1922, **123**, 130—144.

Estimations made of the amount of nitrite produced from nitrate by an extract of potatoes in presence of acetaldehyde, indicate an increase in the reaction with increase of the amount of enzyme used, but not nearly so marked an increase with increasing amount of aldehyde. Neither formaldehyde nor vanillin is as efficient as acetaldehyde. With acetaldehyde, the reaction ceases after 30—60 mins. Atmospheric oxygen does not appear to be harmful, and very dilute acid is favourable, although greater concentrations markedly retard the reaction.—W. O. K.

Ethyl alcohol from western larch (*Larix occidentalis, Nuttall*). E. C. Sherrard. J. Ind. Eng. Chem., 1922, **14**, 948—949.

The western larch contains 8·17% of water-soluble galactan which on hydrolysis with dilute acid gives galactose. This sugar was successfully fermented by a Hungarian beer yeast, *Saccharomyces cerevisiæ*; of the total of 29% of reducing sugar available, 70—80% was fermented with a yield corresponding to 33 galls. of 95% alcohol per ton of dry wood. The wood was digested in an autoclave for 15 min. at 115 lb. steam pressure with 1·8—2·5% of its weight of sulphuric acid, moistened, extracted with water, and the sugar solution neutralised and evaporated. The temperature of fermentation should be 85°—90° F. (30°—32° C.) and the initial acidity not more than "5°."—C. I.

Alcohol; Preparation of industrial absolute — and its application to the preparation of liquid fuel. C. Mariller and Van Ruymbeke. Comptes rend., 1922, **175**, 588—590.

Alcohol of 98·5—99% strength may be prepared by distillation of alcohol-water mixtures, the vapours passing upwards through a column which is traversed in the opposite direction by anhydrous glycerol. Distillation may by this method be carried out more rapidly than in the ordinary processes of preparation of 96% alcohol. The mixture of glycerol and water which is obtained may readily be dehydrated for further use by heating first in air, then *in vacuo*. To obtain alcohol of a purity greater than 99%, a dehydrating salt—such as potassium carbonate, zinc chloride, calcium chloride—is dissolved in the glycerol, the regeneration of which is unaffected by the solute. The difficulty of direct solution of the salt in the glycerol is obviated by adding it in aqueous solution and obtaining a clear anhydrous solution by vacuum evaporation. It is stated that anhydrous glycerin containing 30% of potassium carbonate yields alcohol of 99·9% purity.—H. J. I

Decomposition of citric acid by bacteria. Kickinger. *See* XIXA.

Patents.

Lactic acid; Production of* —— *from rotte potatoes. **Byk-Guldenwerke Chem. Fabr. A.-G G.P. 358,110, 18.12.19.**

Rotten potatoes are washed with water, and th liquor, after agitation, is allowed to settle. Th

upper and lower portions of the liquor, containing respectively light and heavy impurities, are withdrawn, and the middle layer alone is employed for the production of starch for conversion into lactic acid by fermentation.—L. A. C.

Fermentation residues; Process for utilising nitrogenous material in ——. Reichsausschuss für pflanzliche und tierische Oele und Fette G.m.b.H. G.P. 358,118, 7.6.17.

Residues, *e.g.*, vinasse and yeast, obtained after distilling off alcohol produced by fermentation processes, are employed together with material containing carbohydrates for cultivating fat-forming fungi, and, after separation of the fat, are again fermented with yeast. Yeast residues are autolysed before use as above. Vinasses from cellulose waste liquors may be employed either alone or mixed with material containing carbohydrates, for cultivating the fungi.—L. A. C.

XIXa.—FOODS.

Flours; A new method of determining and identifying —— in bakery products and foods by examining the crude fibre. A. Fornet. Chem.-Zeit., 1922, **46**, 969—970.

The degree of milling and the value of flours can be judged by a comparison of their colours with those of standard samples according to Pekar's method, but this method cannot be applied to bakery or food products prepared from flours. The only component of flours unchanged by the baking process is the crude fibre, which can be isolated and compared with standard samples under the microscope. Samples of crude fibre obtained from bakery products agree exceedingly well with those obtained from the original flours, and it is possible to judge from their appearance what kind of flour was used in the preparation of a given food. Photographs are shown of standard samples of crude fibre from 94%, 85%, and 30% wheat flour, isolated from the flour and bread respectively. The method can be extended to the examination of spice, starch, and chocolate powders.—H. C. R.

Citric acid of cow's milk; Decomposition of —— by some bacteria. H. Kickinger. Biochem. Zeits., 1922, **132**, 210—219.

The citric acid content of milk is unchanged when the milk is boiled or pasteurised, but falls off on long standing. In fractionally sterilised milk the citric acid content falls during the first day but remains constant after the third sterilisation. This is not due to bacteria forming lactic acid, but to peptonising bacteria (*B. subtilis, Proteus vulgaris*).—H. K.

Organic bases of the flesh of swine. Materials extracted from muscles. XXI. I. A. Smorodincev. Z. physiol. Chem., 1922, **123**, 116—129.

Using over 2 kg. of pig's flesh, the following approximate figures were found for the content of organic bases: creatine, 0·228%; purines, 0·086%; carnosine, 0·289%; methylguanidine, 0·032%; carnitine, 0·032%. As compared with other animals investigated, the flesh of the pig is particularly rich in creatine and carnosine.—W. O. K.

Silage; Determination of acids in ——. W. Zielstorff and F. Benirschke. Chem.-Zeit., 1922, **46**, 939.

100 g. of the finely chopped silage is boiled with distilled water for 3 hrs. under a reflux condenser in a 2-l. flask in order to destroy any moulds, and afterwards made up to the mark. 100 c.c. of the filtrate, after filtering through a cloth, is heated with kieselguhr for a few minutes under a reflux condenser and filtered through a pleated paper. In most cases a colourless filtrate is obtained and is made up to 200 c.c. and an aliquot part titrated boiling with $N/50$ sodium hydroxide using phenolphthalein as indicator to obtain the total acids. If the filtrate is dark coloured it is diluted until the colour change can be observed. The free volatile acids are obtained by distilling in steam until a drop of the distillate, tested with Congo red, is free from acid. The combined volatile acids are sometimes not completely distilled over even when 800—900 c.c. of distillate has been collected. They are liberated equally well by sulphuric acid and by phosphoric acid.—H. C. R.

Vitamin A from carrots; Researches with ——. H. von Euler. Ark. Kem. Min. Geol., 1922, **8**, [18], 1—7.

The residue of the benzene extract of carrots is very effective in increasing the growth of mice fed on a diet lacking vitamin A. A mixture of the phosphatides, phytosterol, and daucosterol from carrots is also effective.—W. O. K.

Vitamin A; Conditions of activity of ——. H. von Euler. Ark. Kem. Min. Geol., 1922, **8**, [19], 1—10.

A mixture of the dry residues from the benzene extracts of carrots and of butter is more efficient as a source of vitamin A than either residue separately. The efficiency of vitamin A is increased by discontinuous additions of vitamin B.—W. O. K.

Vitamin B; Physiological researches on —— and water-soluble biocatalysts. G. J. Blohm, C. G. Santesson, and H. von Euler. Ark. Kem. Min. Geol., 1922, **8**, [13], 1—27.

Various preparations from yeast and malt which accelerate the growth of yeast lower the blood-pressure if injected into rabbits, reduce the pulse rate, and also affect the breathing. However, they are only very slightly less active after inactivation as biocatalysts by heating, except in the case of specially pure preparations, where the difference is more marked.—W. O. K.

Patents.

Fruit juices, conserves or other products [sugar] from fruits, vegetables, and the like; Manufacture of ——. Plauson's (Parent Co.), Ltd. From H. Plauson. E.P. 186,756, 30.7.22.

Fruits and vegetables, in the presence of either natural or added water are passed through a colloid mill (E.P. 155,836; J., 1922, 357 a). By varying the concentration, the degree of dispersion, and the precipitating agent it is possible to favour selectively the retention or removal of desired substances. Afterwards the purified solution can be concentrated, preserved, or dried by suitable processes. It is claimed that with this treatment a maturing or ripening is effected, due to the high degree of dispersion causing chemical reactions between the various constituents of the fruit, and that the aroma of the juices is uninjured and sometimes even improved. The specification gives examples of the application of this process in the production of a clear wine from grapes, cider free from alcohol, apple conserve or apple butter from apples, a practically quantitative yield of sugar from beetroot, and a valuable cocoa powder free from the valueless cellulose and lignin substances from the cacao bean.—S. G. U.

Desiccator [*for milk powder*]. W. O. Rew, Assr. to California Central Creameries. U.S.P. 1,392,656, 4.10.21. Appl., 17.4.18.

The apparatus comprises a helical pipe built up of short cylindrical sections connected together so that sharp edges are formed inside the pipe at the joints. Sticky particles of partially dried milk from a desiccator of the usual type are fed into the helical pipe and are circulated therein, together with hot air drawn in through a separate inlet, by means of a centrifugal fan. The milk particles are dried by the hot air and are pulverised by repeated contact with the sharp edges of the joints of the pipe. The outlet opening is in the inner wall of the helix, and particles not sufficiently finely ground are driven by the centrifugal force towards the outer wall and past the outlet, through which finely ground milk powder is discharged.

Vegetable material, especially green foodstuffs; Process for preserving ——. R. Aurich. G.P. 357,409, 28.10.20.

Vegetable material is subjected to the action of an electric current while maintained under a high and gradually increasing pressure, whereby the moisture is distributed uniformly throughout the mass, and the electrical conductivity of the material is increased.—L. A. C.

Food for animals; Manufacture of a ——. American Cotton Oil Co., Assees. of C. O. Phillips. E.P. 178,073, 7.2.22. Conv., 5.4.21.

See U.S.P. 1,410,345 of 1922; J., 1922, 343 A.

Pectous material and process of making the same. F. G. Beylik, Assr. to N. W. Schwartzlose. U.S.P. 1,393,660, 11.10.21. Appl., 23.9.20.

Feed-water for boilers; Process of and device for separating air and gases from liquids, particularly ——. C. Hülsmeyer. E.P. 157,790, 10.1.21. Conv., 11.10.15. Addn. to 157,789.

The treatment with metal turnings or shavings or fibrous material described in the previous patent (*cf.* G.P. 288,158; J., 1916, 435) is carried out in a tank interposed in the suction conduit of the device (pump, injector, pulsometer) for feeding the boiler or the like.

Sludge; Process of withdrawing —— *from septic tanks.* K. Imhoff and H. Blunk. G.P. 358,106, 18.11.21.

Before sludge is withdrawn from a septic tank, it is stored for a time in a heated compartment of the chamber under water. Admixture of the sludge with fresh sludge is thereby prevented, and putrefaction is complete before the sludge is blown out of the chamber, *e.g.*, by means of the gases liberated therein.—L. A. C.

Lead arsenate [*insecticides*]; *Manufacture of* —. R. E. Wilson, Assr. to Pittsburgh Plate Glass Co. U.S.P. 1,393,474, 11.10.21. Appl., 1.3.19.

Lead arsenate precipitated from a solution to which a small quantity of chemically inert organic colloid, *e.g.*, 0·02—0·5% of glue, has been added, will remain suspended in water for a very much longer period than ordinary lead arsenate. Alternatively, precipitated lead arsenate may be treated with a solution or emulsion of the colloid.

Arsenical spray; Production of ——. J. D. Riedel A.-G. G.P. 357,874, 7.6.19. Addn. to 301,686 (J., 1922, 726 A).

Metals such as magnesium, or mixtures of, *e.g.*, zinc and sulphur or ferrosilicon and barium peroxide, are used instead of aluminium for volatilising arsenic in the process described in the chief patent. The arsenic compounds may be separated from the heating mixture by a covering of alumina or metal.
—L. A. C.

Feed water for boilers; Process of and device for separating air and gases from liquids, particularly ——. C. Hülsmeyer. E.P. 157,789, 10.1.21. Conv., 11.11.13.

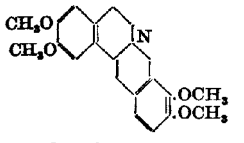
XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Strychnos alkaloids. XXXIV. Preparation of isostrychnine. H. Leuchs and R. Nitschke. Ber., 1922, 55, 3171—3174.

Isostrychnine, $C_{21}H_{22}O_2N_2,3H_2O$ (*cf.* Pictet and Bacovescu, J., 1905, 1123), is conveniently obtained by the action of methyl alcoholic ammonia on strychnine at 140°—160° C. It has m.p. 223°—224° C., $[\alpha]_D = +24 \cdot 1°$ to $+25 \cdot 1°$ in alcohol, $-39 \cdot 47°$ to $-41 \cdot 9°$ in glacial acetic acid. It dissolves in water at 100° C. to the extent of 1 in 130—140 parts. It gives a well-crystallised methiodide, colourless leaflets, m.p. about 223° C. (decomp.) after softening at 215° C., but its other derivatives are generally ill-defined. (*Cf.* J.C.S., Dec.)—H. W.

Alkaloids of the colombo roots; Constitution of the ——. E. Späth and K. Böhm. Ber., 1922, 55, 2985—2995.

Colombamine and jatrorrhizine have been isolated from the colombo root according to the methods of Günzel (J., 1906, 906) and Feist (J., 1907, 1159), but doubts are expressed as to the homogeneity of the fractions which are soluble in potassium carbonate and potassium hydroxide respectively. Complete methylation of the fractions gives identical completely methylated ethers, which on reduction yield the same hydro-derivative, the properties of which are in complete harmony with those of the compounds described by Feist. Somewhat unexpectedly it is found that the methyl ether and its tetrahydro-derivative are identical with palmatine (see annexed formula)



and tetrahydropalmatine, the constitution of which has been established by Späth and Lang (J., 1922, 117 A). The relationships of the various alkaloids of the colombo root appear therefore to be simpler than was expected. There are present, in addition to the completely methylated palmatine, phenolic bases in which probably one or more of the methoxy groups of palmatine are replaced by hydroxy groups or by phenolic oxygen united to a complex capable of being readily eliminated. (*Cf.* J.C.S., Dec.)—H. W.

Greasewood (Sarcobatus vermiculatus); Toxic constituent of ——. J. F. Couch. Amer. J. Pharm., 1922, **94**, 631—641.

The common greasewood of the mountain States, collected in Utah, was investigated for toxic constituents. Toxic alkaloids, glucosides, and saponins were not found in any of the extracts of the plant, and tests for hydrocyanic acid or its compounds were all negative. Large quantities of potassium and sodium oxalates were found, total oxalate calculated as anhydrous oxalic acid amounting to 11·54% of the weight of the dried plant. These compounds are responsible for the cases of poisoning which have occurred amongst sheep that had been grazing on the plant.—G. F. M.

Rhinanthin and aucubin: rhinanthin is impure aucubin. M. Bridel and M. Braecke. Comptes rend., 1922, **175**, 640—643.

The substance obtained in 1870 by Ludwig from seed of *Rhinanthus Crista-galli* and known as "rhinanthin" is not a pure product but a mixture of sucrose and aucubin in different proportions according to its origin. The name "rhinanthin" therefore does not designate a well-defined substance and should no longer be used.—H. J. E.

Saponins. VIII. Saponins from the leaves of Aralia montana, Bl. (Galacturonoid saponins and their magnesium and calcium salts). A. W. van der Haar. Ber., 1922, **55**, 3041—3069.

The powdered leaves and stems of *Aralia montana*, Bl. contain about 1·6% of saponins, which are members of at least three groups. Free saponins are present in addition to their calcium and magnesium salts; these are precipitated by basic but not by normal lead acetate. The amount of saponins appears to be variable. In the isolation of the saponins it is necessary that the extraction with methyl alcohol (95%) should be followed by treatment with ethyl alcohol (45%), since otherwise the salts of the saponins remain undissolved. The saponins are poisonous to fishes and exhibit hæmolytic action; the magnesium salt is about three times as potent as the free saponin. Proximate analyses and quantitative hydrolysis show the saponin to contain: water, 4·8; ash, 1·8; *d*-galacturonic acid, 1·8; *l*-arabinose, 13·3; methylpentoses, 2·1; *d*-glucose, 16·15; *d*-galactose, 2; sapogenin, 50%. Analysis of the magnesium and calcium salts of the saponin gives water, 7·2; ash, 5·3; *d*-galacturonic acid, 7·39; arabinose, 8·64; methylpentose, 6·24; *d*-glucose, 5·6; *d*-galactose, 3; sapogenins, 31·2%. Other saccharides or acids are not present. The crude mixture of sapogenins readily yields araligenin, $C_{25}H_{40}(OH).CO_2H$, which separates from ethyl alcohol with varying amounts of solvent of crystallisation, causing the melting point of the product to vary. A uniform material, having $[\alpha]_D = +71°$ in a mixture of alcohol and pyridine, is obtained when the crystals are heated at 150° C. Distillation of araligenin with zinc dust in an atmosphere of hydrogen gives carbon dioxide, water and a mixture of terpene hydrocarbons which is separable by distillation with steam into a volatile and a non-volatile fraction; the reaction may be represented by the scheme:

$$C_{25}H_{40}(OH).CO_2H = (C_5H_8)_5 + CO_2 + H_2O.$$

(*Cf.*, J.C.S., Dec.)—H. W.

Phytosterols of ragweed pollen. F. W. Heyl. J. Amer. Chem. Soc., 1922, **44**, 2283—2286.

The unsaponifiable fraction of the ether extract of ragweed pollen contains a new phytosterol, ambrosterol, $C_{20}H_{34}O,H_2O$, m.p. 147°—149° C., a phytosterol, $C_{27}H_{44}O$, m.p. 147·5°—148° C, considerable amounts of a more highly oxygenated substance, probably an oxyphytosterol, traces of a hydrocarbon, and appreciable quantities of the higher homologues of the methyl alcohol series, of which cetyl and octadecyl alcohols were identified.—W. G.

Xanthosterol; Identity of —— with lupeol. A. J. Ultée. Bull. Jardin Botan. Buitenzorg, 1922, **4**, 315—316. Chem. Zentr., 1922, **93**, III., 1050.

The identity of lupeol (Cohen, Arch. Pharm., 1907, **245**, 236) with xanthosterol (Dieterle, J., 1920, 81 A) has been demonstrated by chemical and physical tests with the substances themselves and with their acetyl and benzoyl derivatives. The new phytosterol described by Oestling (Ber. deuts. Pharm. Ges., 1914, **24**, 308) is also probably identical with lupeol.
—D. F. T.

Toxins and antitoxins; Chemical nature of ——. E. Salkowski. Biochem. Zeits., 1922, **132**, 84—88.

The author records some unpublished experiments made in 1896 on the preparation of diphtheria antitoxin free from protein. The diphtheria antitoxin serum was saturated with sodium chloride, treated with two volumes of saturated sodium chloride solution, and trichloroacetic acid added so long as a precipitate was formed. The protein precipitate carries the antitoxin down with it. The product is filtered off and triturated with water, which dissolves the antitoxin. The solution is free or practically free from protein. The same process was used by Blumenthal (Z. klin. Med., 1896, **30**) for preparing protein-free toxin from the spinal marrow of a case of tetanus.—H. K.

Thyroid; New constituent of the ——. U. Sammartino. Biochem.-Zeits., 1922, **132**, 293—294.

Fresh thyroids (400 g.) were extracted with hot dilute acetic acid, the solution concentrated and precipitated with basic lead acetate. The filtrate, freed from lead, was concentrated and precipitated with alcohol. The filtrate, on fractional crystallisation with picric acid, gave potassium picrate, then a red picrate which did not melt at 300°, and a picrate of m.p. 255°—295° C. After removal of picric acid from the mother liquors addition of alcohol precipitated a crystalline substance, m.p. 225°—228° C., containing calcium, carbon, nitrogen, and a high percentage of oxygen.—H. K.

Melanin; Formation of —— from organic substances. O. Adler and W. Wiechowski. Ber., 1922, **55**, 3030—3038.

The ability of a very large number of organic substances to form melanin acids has been examined by dissolving or suspending the substance (0·1—0·2 g.) in water (10—12 c.c.) and adding 3—4 drops of $N/1$ ferric chloride solution. The solution is divided into two parts, one of which serves as a control. Hydrogen peroxide (3%, 0·2—0·5 c.c.) is added to the other portion. If the substance is capable of producing melanin acids, a dark, sometimes almost black, coloration is developed after short heating or sometimes even at the atmospheric temperature. Protracted heating is to be avoided as the melanin acids are readily oxidised further to colourless substances. The dark mixture is subsequently rendered alkaline with sodium hydroxide, when the melanin acid dissolves or remains dissolved as the case may be. The test itself must be performed in neutral or faintly acid solution. Under the prescribed conditions melanin acids are produced only from cyclic substances. Compounds belonging to the terpene, triphenylmethane, phenanthrene, anthracene, and pyridine series exhibit little or no tendency towards the formation of melanin acids. Very marked ability is shown by the aniline group, phenylhydrazine and its substituted derivatives, phenols, quinone, aromatic monoaldehydes and ketones, aromatic monocarboxylic, and phenolmonocarboxylic acids, and aromatic amino-acids. A positive reaction is given by *p*-diphenol, benzidine, and tolidine, but scarcely by dianisidine. The naphthols and naphthylamines give melanin acids, whereas naphthalene itself does not. Among heterocyclic compounds, thiophenic acid, pyrrole, coumarone, indole, and tryptophan give melanin acids. Quinoline hydrochloride and the hydroxyquinolines give a faintly and strongly positive action respectively. Positive results are also given by isoquinoline, acridine, and compounds of the tropine, cinchonine, and morphine groups. The entrance of halogen or the arsinic residue into the aromatic nucleus diminishes or destroys the tendency towards the formation of melanin acids, whereas the sulphonic and nitro groups have no restrictive action. The production of melanin acids is facilitated by the presence of amino groups but impeded by the introduction of methyl groups. Positive results are obtained with the methyl or ethyl esters or methyl ethers of substances which themselves give the melanin reaction, whereas a negative result is produced if a cyclic group is involved in the formation of the ester or ether or if an inorganic component is present.—H. W.

Arsphenamine [salvarsan]; Sulphur content of —— and its relation to the mode of synthesis and toxicity. III. W. G. Christiansen. J. Amer. Chem. Soc., 1922, **44**, 2334—2342.

In reducing 3-nitro-4-hydroxyphenylarsonic acid, $C_6H_3(NO_2)(OH)AsO_3H_2$, to salvarsan the formation of relatively toxic products with a high sulphur content is not due to impurities in commercial sodium hydrosulphite. The salvarsan base is fairly uniform in regard to toxicity and sulphur content irrespective of the period of formation during the reduction. Aminohydroxyarseno compounds in general contain the fewest sulphur atoms when prepared from the amino-acids. The hydroxyl hydrogen atom ortho to the nitro group seems to play an important part in the formation of arseno compounds of the type under consideration, and fixation of the hydroxyl hydrogen atom in the nitrohydroxyarsonic acids tends to make the hydrosulphite reduction abnormal, and the products, when they can be isolated, contain more sulphur than analogous substances prepared without fixation of this hydrogen atom. A number of new arsonic acids are described. (*Cf.* J.C.S., Dec.)—W. G.

Botanical chemical notes. E. O. von Lippmann. Ber., 1922, **55**, 3038—3041.

During an exceptionally warm summer drops of nectar fell from the garden foxglove; these solidified readily and contained large quantities of sucrose. Trehalose has been isolated from a sample of material similar to ergot, found on wild oats grown near Kessingen (*cf.* Tanret, J., 1922, 345 A). An exudation from the stems of a quince tree which had been damaged by smoke and was nearly dead consisted of a viscous white gum which was very rapidly and almost completely hydrolysed by dilute acid to *i*-galactose. Malic, citric, tartaric, and succinic acids have been isolated from the berries of the mountain ash; the nature and relative amounts of the acids appear to depend on the ripeness of the berry and the particular variety.—H. W.

Guanidine formation in fused mixtures of dicyanodiamide and ammonium salts; Mechanism of ——. J. S. Blair and J. M. Braham. J. Amer. Chem. Soc., 1922, **44**, 2342—2352.

When dicyanodiamide $(H_2CN_2)_2$, is fused with ammonium thiocyanate the amount of diguanide thiocyanate, $H_2NC(:NH)NHC(:NH)NH_2,HCNS$, in the fused mass increases at first with the time of fusion and then reaches a maximum and slowly diminishes. On the other hand guanidine thiocyanate $H_2NC(:NH)NH_2,HCNS$, does not make its appearance until the diguanide thiocyanate has nearly reached its maximum concentration. Further when diguanide nitrate is fused with ammonium nitrate the greater part of it is converted into guanidine nitrate. These results support the view as to the cyanoguanidine structure for dicyanodiamide, $H_2NC(:NH)NHCN$, and also for the formation of the diguanide salt as a necessary intermediate compound in the formation of guanidine salts from dicyanodiamide by fusion with an ammonium salt.—W. G.

Cyclohexanol; Preparation of ——. A. Brochet. Comptes rend., 1922, **175**, 583—585.

The preparation of cyclohexanol by hydrogenation of phenol in presence of nickel must be carried out under pressure, with constant shaking. The theoretical yield is obtained by working at temperatures between 100° and 150° C. under a pressure of 10—15 atm. The product is filtered to remove nickel and washed first with dilute caustic soda, then with water. It may be distilled without preliminary dehydration; water comes over first with only a little hexanol, and almost the whole of the latter then distils at 160°—161° C. The activity of the catalyst diminishes with repeated use and it is preferable to use a considerable quantity to avoid constant renewal.—H. J. E.

Tartaric acid; Neutralisation of ——, by potash in presence of alkaline-earth chlorides. L. J. Simon and L. Zivy. Comptes rend., 1922, **175**, 620—622.

A mixture of tartaric acid and a strong acid may be estimated by two titrations with standard alkali using phenolphthalein for one determination and methyl orange for the other. The former gives an end-point when the normal tartrate is formed, the latter on formation of the acid tartrate. Chlorides of alkaline-earth metals interfere with the estimation when methyl orange is used but not with phenolphthalein. In the case of excess of calcium chloride, each molecule of tartaric acid behaves as if it were replaced by two molecules of hydrochloric acid; when the chloride is less than equivalent to the tartaric acid each molecule acts quantitatively. —H. J. E.

Isopropyl alcohol; Oxidation of —— with potassium permanganate. W. L. Evans and L. B. Sefton. J. Amer. Chem. Soc., 1922, **44**, 2271—2276.

In the presence of potassium hydroxide isopropyl alcohol is oxidised by potassium permanganate to give carbon dioxide, and oxalic and acetic acids. No acetone is obtained unless the temperature does not exceed 25° C. and the concentration of the alkali 2·12 g. per litre. The amounts of oxalic and acetic acids produced increase and decrease respectively as the initial concentration of the alkali increases from zero to 0·1—0·2 *N*. The general effect of rise in temperature is to increase the amount of carbon oxidised to carbon dioxide to slightly more than one atom per molecule of alcohol.—W. G.

Acetone; Oxidation of —— with potassium permanganate. W. L. Evans and L. B. Sefton. J. Amer. Chem. Soc., 1922, **44**, 2276—2283. (*Cf. supra.*)

By the oxidation of acetone with potassium permanganate in neutral or alkaline solution at 25°, 50°, or 75° C., the sole products are oxalic and acetic acids and carbon dioxide. The yield of oxalic acid increases with rise in temperature and the concentration of the alkali, while that of acetic acid diminishes with decrease in temperature and with rise in the concentration of the alkali. The production of carbon dioxide increases with rise in temperature.—W. G.

Amines; Decomposition of —— in the vapour stage. F. W. Upson and L. Sands. J. Amer. Chem. Soc., 1922, **44**, 2306—2310.

When ethylamine vapour is passed over kaolin at 700° C. the chief products are ammonia, hydrogen cyanide, and a substance which is probably acetonitrile, together with smaller quantities of hydrogen and nitrogen. At 500° C. no hydrogen cyanide is produced, a larger amount of ammonia is formed, and the gaseous products contain relatively large amounts of unsaturated hydrocarbons. At 1000° C. the nitrogen appears exclusively as free nitrogen and much of the hydrogen as free hydrogen. The hydrocarbons are almost entirely saturated and to a large extent consist of butane. The decomposition of propylamine under similar conditions at 700° C. proceeds in a similar manner to that of ethylamine. —W. G.

Ethylene; Absorption of —— by sulphuric acid. Production of ethyl alcohol, diethyl sulphate, and liquid hydrocarbons. A. Damiens. Comptes rend., 1922, **175**, 585—588.

Absorption of ethylene by sulphuric acid in presence of cuprous sulphate gives rise to diethyl sulphate, ethylsulphuric acid, and a mixture of saturated hydrocarbons of the nature of petrol, the products depending on the conditions. In both cases the first stage of the reaction, formation of the complex Cu_2SO_4,nC_2H_4, is identical, but the decomposition of the complex may take place in two directions. Absorption in the cold with 1—5% of catalyst present results in an almost theoretical yield of ethylsulphuric acid, but if the acid is below 97% concentration, diethyl sulphate is formed in addition. If the catalyst is heated with the acid and the ethylene subsequently absorbed cold in presence of mercury or mercurous sulphate, a mixture of hydrocarbons of sp. gr. 0·77 and b.p. 110° C. and upwards is obtained.—H. J. E.

Nitro-compounds; Detection of ——. H. J. Prins. Perf. Essent. Oil Rec., 1922, **13**, 355.

The accelerating effect of nitrobenzene on the reaction velocity of metals with weak acids is applied to the detection of this substance in benzaldehyde. The reaction is not exclusively specific for nitro-compounds, as organic peroxides have the same property, but only oils rich in terpenes which contain peroxides through exposure to air show the reaction, and then only feebly. Wormseed oil contains the peroxide, caridol, which shows the reaction in a marked degree, but this can hardly give rise to confusion, as 5% of nitrobenzene in benzaldehyde reacts more rapidly then pure wormseed oil. Benzaldehyde peroxide does not show the nitrobenzene reaction at all. The reaction is carried out as follows: A solution of 2 c.c. of the oil in 6 c.c. of 80% acetic acid is heated for 1 min. with a small piece of tinfoil. In presence of 5% of nitrobenzene the tin disappears immediately on boiling, with 1% the tin turns dark and disappears about 10 mins. after the mixture is heated, with 0·1% the tin turns black after about 10 mins., with 0·01% the tin becomes grey black after standing over night, and with pure benzaldehyde the tin retains its bright surface. In a similar manner the presence of 0·1% of artificial musk in perfumes can be detected.—G. F. M.

Nitrobenzene (mirbane oil); Detection of —— [in benzaldehyde]. A. Reclaire. Perf. Essent. Oil Rec., 1922, **13**, 356.

The pink to red coloration with a very dilute alcoholic solution of caustic soda described by Pickering (Chem. Trade J., 1922, **70**, 144) as characteristic of nitrobenzene is not a reaction of this substance at all, but of dinitrothiophene, which is often present in commercial nitrobenzene. The detection of nitrobenzene by its odour after dissolving the benzaldehyde as its bisulphite compound is possible, but a determination by this method is only fairly correct if 10% or more is present in the aldehyde, as nitrobenzene dissolves in aqueous aldehyde bisulphite solution to a certain extent, and if less than 5% is present it does not appear as a second layer at all. The method of Pinoff (Pharm. Zentralh., 1921, **62**, 610) depending on the formation by formaldehyde-ammonia of an emulsion with benzaldehyde but not with nitrobenzene, does not appear satisfactory, as no difference could be observed with mixtures containing 1—10% of nitrobenzene.—G. F. M.

Abietic acid. A. Madinaveitia. Anal. Fís. Quím., 1922, **20**, 185—189.

Analyses of abietic acid were in agreement with the formula $C_{19}H_{28}O_2$ (*cf.* Sureda Blanes, J., 1915, 878). The results of the hydrogenation of the ethylenic linkages by Willstätter's method indicate that the carboxyl group is attached to a tertiary carbon atom, and since the nucleus of the molecule must be retene, which is formed by the catalytic dehydrogenation of abietene, the following formula for abietic acid is suggested:

$$\begin{array}{l}(CH_3)_2CH.C\!-\!CH_2\!-\!CH.CH{:}CH.CH.CH_2.CH(CH_3)\diagdown \\ \qquad\quad \| \qquad\qquad\quad | \qquad\qquad\qquad\quad | \qquad\qquad\qquad\qquad\quad > CH_2 \\ \qquad\quad CH.CH_2.CH \text{————} C(CO_2H) \text{—} CH_2 \diagup \end{array}$$

—G. W. R.

d-Camphor; Catalytic reduction of ——. I. S. Komatsu and B. Masumoto. Mem. Coll. Sci. Kyoto, 1921, 5, 225—232.

When camphor was passed with hydrogen over reduced nickel heated to 175°—185° C., and the product fractionated, a hydrocarbon, $C_{10}H_{18}$, was obtained, which seems to be identical with the isocamphane obtained by Lipp (Annalen, 1911, **382**, 279) by the catalytic hydrogenation of camphene. In addition to this substance, some *d*-borneol was obtained. The same *l*-isocamphane was obtained by catalytic reduction in the same manner of both *d*- and *l*-borneol.—E. H. R.

Sandalwood oil; Solubility of West Australian ——. H. V. Marr. Perf. Essent. Oil Rec., 1922, **13**, 366.

In reference to the statements made by Somerville regarding the solubility of West Australian sandalwood oil (J., 1922, 647 A), it is pointed out that the opalescence which is produced on diluting solutions in 70% alcohol is not a peculiar feature of the oil from *Santalum cygnorum* but is typical also of the oil from *S. album*. In fact in all cases where the solubility of the two oils in 70% alcohol has been compared, that of the West Australian variety has always proved superior, and it has remained miscible on the addition of a greater number of volumes of 70% alcohol before opalescence occurred than any samples of *S. album* oil examined, the range of solubility in the former cases being about 4·5 to 11 vols. and in the latter about 6—10 vols. —G. F. M.

Citronella oil; [Determination of] total geraniol content of ——. M. S. Salamon. Perf. Essent. Oil Rec., 1922, **13**, 357—358.

A criticism of the paper by De Jong and Reclaire (J., 1922, 836 A). It is pointed out that the equivalent of 0·1 c.c. of $N/2$ KOH is 0·0075 g. of geraniol and not 0·075 g. as stated. The importance of accurately measuring the volumetric solution is emphasised, as a difference of 0·1 c.c. of $N/2$ KOH represents a difference of 0·8% in geraniol content. As the acetylated oil is somewhat dark it is not considered possible to neutralise it accurately with $N/2$ KOH by dissolving 1·5 g. in only 2 c.c. of alcohol, and 20 c.c. of $N/2$ KOH is not considered sufficient to provide an adequate excess in the saponification of 1·5 g. of acetylated oil. Attention is drawn to the influence of chlorides in the acetic anhydride used for acetylation, experiments indicating that an anhydride containing chloride may increase the so-called geraniol content by as much as 2·5%.—G. F. M.

Citronella oil; [Determination of] total geraniol content of ——. De Jong and A. Reclaire. Perf. Essent. Oil Rec., 1922, **13**, 358.

If the acetylated oil is accurately washed out and if pure sodium acetate free from carbon and tarry matter is used for the acetylation the oil is not dark and the neutralising gives no trouble. As saponification often darkens the oil, 50 c.c. of water is added as a medium for the titration. The use of 20 c.c. of $N/2$ KOH for the saponification is an excess of 45% above the theoretical amount, and there is no object in using more.—G. F. M.

Oil of lemon; Adulteration of —— *with terpenes.* G. Ajon. Giorn. Chim. Ind. Appl., 1922, **4**, 389—391.

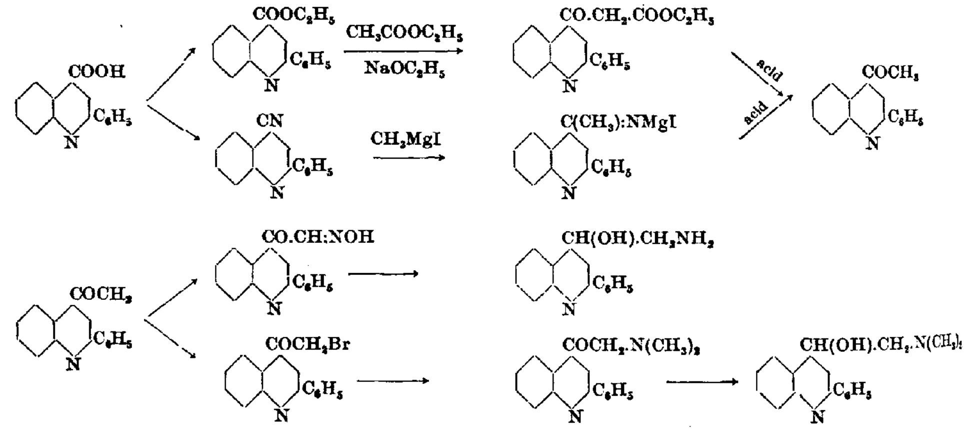
The methods ordinarily used for the estimation of citral in lemon oil yield, not the citral alone, but the whole of the carbonyl compounds present, calculated as citral; to this figure the author gives the name "analytical citral." Certain of these carbonyl compounds (citral) react with dilute sodium sulphite solution to form sulphonic compounds, whereas others (citronellal, methylheptenone) do not thus react. Lemon oil adulterated by added citral and terpenes will show a higher content of methylheptenone than the corresponding genuine oil, so that treatment with sodium sulphite will reveal differences between the genuine and the adulterated oil. Experiment shows, indeed, that the first distillates of an oil of lemon adulterated in the above way give, for the content of "analytical citral," figures higher than those yielded by the corresponding genuine products, whilst the last distillates, in which more especially the citral and citronellal are collected, are greatly impoverished by treatment with the sulphite. These conclusions are confirmed by the numerical and graphical results given.—T. H. P.

Urea. Pincussen. *See* XXIII.

Patents.

Aminoalcohols of the quinoline series; Manufacture of ——. O. Y. Imray. From Soc. Chem. Ind. in Basle. E.P. 185,913, 20.7.21.

Aminoalcohols derived from 2-phenylquinoline-4-carboxylic acid are obtained by converting the acid, its ester, or nitrile, into a 2-phenylquinolyl-4-alkylketone, and either reducing the latter through its isonitroso-compound to the 2-phenylquinolyl-4-aminoalcohol, or causing the ketone halogenised in the alkyl group to react with an amine, and reducing the 2-phenylquinolyl-4-alkylaminoketone thus produced to the corresponding amino-alcohol. The series of reactions is represented by the following scheme:



2-Phenyl-4-quinolylmethylketone forms yellow crystals, m.p. 75° C., and the preparation and properties of its hydrobromide, m.p. 240° C., its isonitroso-compound, m.p. 182°., and the bromo-derivative, m.p. 91° C., are described in detail. By the reduction of the isonitroso-compound with zinc dust and formic acid 2-phenylquinolyl-4-aminoethanol dihydrochloride is obtained in yellowish crystals, m.p. 145° C. The free base is somewhat unstable. Substituted aminoethanol derivatives are obtainable only from the bromo-ketone, which reacts for example with dimethylamine in benzene solution to give the hydrobromide of 2-phenylquinolyl-4-dimethylaminoethanone, m.p. 260° C., and this sub-

stance on reduction with hydrogen in presence of platinum black is converted into the corresponding 2-phenyl-4-quinolyldimethylaminoethanol, the dihydrochloride of which is a feebly yellowish powder soluble in water, m.p. 175° C. (with decomp.). The dihydrochloride of the corresponding diethylamino-compound melts at 180° C., and of the piperididoethanol at 199° C. These compounds are all stated to be of therapeutic value. (*Cf.* J. S.C., Dec.)
—G. F. M.

Crotonic acid; Production of —— from crotonaldehyde. Elektrizitätswerk Lonza. E.P. 165,728, 27.6.21. Conv., 2.7.20.

THE oxidation of crotonaldehyde to crotonic acid by means of oxygen is greatly accelerated by using a manganic salt, preferably manganic acetate in solution in glacial acetic acid, as catalyst. A manganous salt can be used initially if desired, but it is preferable to oxidise it to the manganic state, as it is only under those conditions immediately operative. *Example*: 1·5% of potassium permanganate is gradually added to a 10% solution of manganous acetate in glacial acetic acid at 115° C. The solution is then diluted with acetic acid to a manganese content of 0·1—0·2%, and 20 litres is stirred with 15 kg. of crotonaldehyde whilst oxygen is led through the mixture. When no more oxygen is absorbed the acetic acid is distilled off and a residue of crotonic acid in 98—99% yield remains and can be purified by recrystallisation.—G. F. M.

Ethylene and other unsaturated hydrocarbons; Process of preparing ——. W. H. Ross, Assr. to W. L. Evans. U.S.P. 1,392,852, 4.10.21. Appl., 1.6.20.

A NICKEL catalyst prepared from nickel nitrate (preferably with addition of an alkaline-earth compound or other impurity which minimises sintering of the nickel during reduction) by distribution on pumice, heating, and reduction in hydrogen, is treated repeatedly with acetylene, followed by exhaustion of the reaction products, until all the adsorbed hydrogen is removed from the catalyst. A mixture of equal parts of acetylene and hydrogen is then passed over the catalyst, at a temperature below 150° C., whereby a product containing 80—90% of ethylene is obtained.

Aldehydes and other oxidation products; Process of making ——. C. H. Bibb, Assr. to J. T. Bibb, sen. U.S.P. 1,392,886, 4.10.21. Appl., 27.10.19.

HYDROCARBONS are converted into alcohols, aldehydes, alcohols, and other oxidation products by heating with oxygen and a small quantity of a gaseous catalyst containing oxygen (*e.g.*, nitrogen oxides). The process is described as applied to the preparation of formaldehyde from methane (natural gas).

4-Dimethylamino - 1-phenyl-2.3-dimethyl-5-pyrazolone; Preparation of a derivative of —— readily soluble in water. Akt.-Ges. für Anilin-Fabr., Assees. of M. Bachstez. G.P. 357,751, 25.9.20.

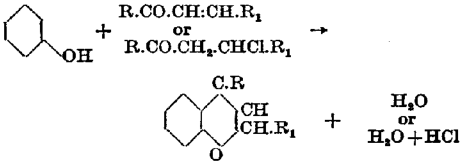
AN aqueous solution containing the sodium or other water-soluble salt of 4-ethoxyphenylmalonamic acid and 4-dimethylamino-1-phenyl-2.3-dimethyl-5-pyrazolone in equimolecular proportions is evaporated to dryness at 100° C., yielding an oily product which crystallises on rubbing. The product possesses therapeutic value as a febrifuge and sedative, and can be applied as subcutaneous injections.
—L. A. C.

Quinine; Preparation of a derivative of ——. Akt.-Ges. für Anilin-Fabr. G.P. 357,753, 19.10.20.

THE 4-ethoxyphenylmalonamic acid salt of quinine, m.p. 72°—73° C., which has therapeutic value as an analgesic and febrifuge, is prepared either by melting together equimolecular proportions of quinine and 4-ethoxyphenylmalonamic acid and crystallising the product from hydrolysing solvents, or by reaction between equimolecular proportions of the component compounds or their salts in the presence of hydrolysing solvents.—L. A. C.

Condensation products of α,β-unsaturated ketones and phenols; Preparation of ——. Chem. Fabr. vorm. Weiler-ter Meer. G.P. 357,755, 27.3.20.

α,β-UNSATURATED ketones, or their acid addition products, condense with phenols in the presence of acid condensing agents in accordance with the equations:—



If highly reactive phenols, such as resorcinol or N-substituted *m*-aminophenol, are employed, the reaction is nearly quantitative, yielding coloured products suitable for the preparation of dyestuffs and for use in medicine. Examples are given of the preparation of products from phenols such as phenol, resorcinol, pyrogallol, and *m*-dimethylaminophenol, and ketones such as benzalacetone, benzalacetophenone, *m*-hydroxybenzalacetone, etc.
—L. A. C.

[Carbamic] ester of trichloroethyl alcohol; Production of a ——. Farbenfabr. vorm. F. Bayer und Co. G.P. 358,125, 14.9.20.

CARBAMIC acid trichloroethyl ester, m.p. 64°—65° C., a soporific of which the toxic dose is much greater than the effective dose, is prepared either by prolonged reaction between ethereal solutions of trichloroethyl alcohol and urea chloride, with subsequent separation of the ester by evaporation and crystallisation of the product from petroleum ether, or by the action of carbonyl chloride on a solution of trichloroethyl alcohol in benzene in the presence of quinoline, and subsequent treatment of the trichloroethyl alcohol chlorocarbonate thus produced with ammonia.—L. A. C.

Thyroid gland; Preparation of a serum for treating diseases of the ——. J. Dreising. G.P. 358,148, 24.9.13.

ANTITHYROID serum (*e.g.*, the antithyreoidin of Möbius) is mixed with dilute sodium chloride solution and a solution of paranephrin (Merck) in 0·1% hydrochloric acid, a small quantity of phenol is added, and the mixture is concentrated at a low temperature under such conditions that no precipitate is formed. An anæsthetic, *e.g.*, novocaine, is added to the solution, which is then filtered through a bacteria filter, and preserved in bottles. Sterilisation of all materials which come in contact with the serum is essential. The product is considerably more active than ordinary antithyroid serum.

Depilatory. P. Fröschel and R. Weiss. G.P. 358,149, 1.8.18. Conv., 26.7.18.

METALLIC salts which yield insoluble or sparingly soluble hydroxides are added to depilating agents containing alkali or alkaline-earth sulphides. For example barium sulphate, strontium sulphide, pulverised dry vegetable mucilage, and crystallised aluminium sulphate are triturated so as to form a uniform mixture, which is mixed to a creamy mass with water when required for use. The mixture does not injure the skin.

Aminopyridines; Preparation of —— Chem. Fabr. auf Actien (vorm. E. Schering), H. Emde, and H. Horsters. G.P. 358,397, 4.8.20.

Aminopyridines are prepared by the action of ammonia on pyridine or its homologues in the presence of alkali metals. For example, anhydrous pyridine is added slowly to toluene at 80° C. containing finely divided sodium in suspension, and ammonia is simultaneously passed into the solution. When the sodium has been used up, the solution is maintained at 130° C. until no more ammonia is absorbed; the bases are then extracted with ether, and, after separating the solvent, the product is distilled *in vacuo*. 2-Aminopyridine distils at 103°—110° C., and 4.4′-dipyridyl at 170°—180° C., both under 20 mm., while 4-aminopyridine separates from the residue. 6-Amino-2-methylpyridine (α′-amino-α-picoline), b.p. 120°—130° C., under 20 mm., is prepared in a similar manner from 2-methylpyridine (α-picoline).—L. A. C.

Diaminodi-p-xylylmethane; Preparation of —— from commercial xylidine. Farbw. vorm. Meister, Lucius, und Brüning. G.P. 358,398, 4.7.20. Addn. to 270,663 (J., 1914, 474).

Sufficient formaldehyde is added to a solution of commercial xylidine hydrochloride to convert the *p*-xylidine present into diaminodi-*p*-xylylmethane, the product is neutralised with alkali, distilled in a current of steam, and then treated as described in the chief patent.—L. A. C.

Optically active aromatic amino alcohols; Manufacture of ——. O. Y. Imray. From Society of Chemical Industry in Basle. E.P. 187,129, 4.10.21.

See U.S.P. 1,423,101 of 1922; J., 1922, 878 A.

XXI. — PHOTOGRAPHIC MATERIALS AND PROCESSES.

Photographic sensitivity; Studies in ——. *I. Distribution of sensitivity and size of grain in photographic emulsions.* E. P. Wightman, A. P. H. Trivelli, and S. E. Sheppard. J. Franklin Inst., 1922, **194**, 485—520.

The sensitivity of the halide grains of a photographic emulsion is discussed from the points of view of distribution of a photocatalyst among the grains, and of a discrete structure of the radiation energy. The work of Slade and Higson is criticised (*cf.* J., 1921, 324 A). An approximate theory of the density-exposure function for certain limited conditions is developed. It is shown that under certain conditions the first derivative of the density exposure function may correspond with the intensity-variation function. The results of determinations of grain size-frequency curves for various emulsions are given (*cf.* J., 1922, 119 A) and compared with the sensitometric characteristics of the emulsions. The relation of grain size to sensitivity is considered from the points of view of the "quantum" theory of sensitiveness and of the "emulsification-nucleus" hypothesis. So far, a crucial distinction cannot be made between these two theories.—W. C.

Photographic emulsions; Sensitometry of —— and a survey of the characteristics of plates and films of American manufacture. R. Davis and F. M. Walters, jun. U.S. Bureau of Standards, Sci. Paper 439, 1922. 120 pages.

About 90 different brands of sensitive plates and films were investigated for speed, development factors, colour sensitiveness, filter factors, scale, and resolving power, and the curves and figures for each of these factors are given for 86 different brands of sensitive material. The paper includes a review and description of the various properties of plates and films and their measurement; a detailed description of the apparatus and methods employed in the standard systems of measurement; and a full account of the experimental results of the tests.—W. C.

Photographic plates; Study of the "threshold value" of —— by counting the grains. W. Noddack, F. Streuber, and H. Scheffers. Sitzungsber. Preuss. Akad. Wiss. Berlin, 1922, 210—213. Chem. Zentr., 1922, **93**, IV., 980.

The source of light used was of wave-length 436 μμ, the brightness being $4{\cdot}44\times10^{-7}$ Hefner candles. Plates were exposed for varying times, the longest exposure being that required to produce just visible blackening on development (50—100 secs. at 1 m.), the other exposures being less by a factor of 2 in each case. After development and fixing, the grains were counted in the microscope or on photomicrographs, and the "fog" grains in unexposed parts of the plates were subtracted. The "threshold value" can be easily ascertained by this method. The increase in number of developed grains is not proportional to the intensity of the light, but is less than required by direct proportionality with increasing exposure. This is explained by the fact that with increasing exposure a greater number of grains would be hit by several quanta, and the probability of one grain being hit by several quanta will increase with its size. This accounts for the fact that very sensitive (coarse-grained) plates give a flatter curve than small-grained emulsions.—W. C.

Photographic exposure; Quantum theory of ——. L. Silberstein and A. P. H. Trivelli. Phil. Mag., 1922, **44**, 956—968.

Additional experiments on the authors' light quatum theory of photographic exposure (*cf.* Phil. Mag., 1922, **44**, 257). This theory assumes the distribution of active centres in the halide crystals according to the laws of chance, and the occurrence of light "darts" of definite cross-section, a grain being made developable only when fully struck by a light dart. A clump of silver halide grains behaves as a photographic unit, since if one of the component grains is made developable, the whole clump may be reduced by a sufficiently long development. In a number of observations the targets were classified, according to the number of grains in the clump, but in the later experiments a new method of division of the targets into broad classes according to area was adopted. The effect of length of exposure to a constant light source, and the number of clumps made developable is in agreement with the authors' theory.—W. E. G.

Photographic print-out images; Colour change of —— on fixing. F. Formstecher. Phot. Ind., 1921, 590. Chem. Zentr., 1922, **93**, IV., 999.

The reversible colour change produced on immersing a print in distilled water is probably due to an alteration in the distance between the grains as a result of swelling of the film. Irreversible colour changes are produced by the action of ions on the film, causing a coagulation of colloidal silver to coarse-grained yellow-brown silver. The medium exerts an important influence on this change. Since the colour of a print varies between red and blue according to the composition and degree of ripening of the emulsion, the fixed image also takes on different tints. The bluer the copy the greater is the deviation from the normal yellow-brown colour of coagulated silver, and the redder are the tones obtained on fixing. The colours of Poitevin photochromes depend on the optical resonance of the silver ultramicrons, and each contact with solutions brings about coagulation and so alters the colours.—W. C.

inacyanols. König. *See* IV.

Patent.

elluloid [photographic] films; Reducing the inflammability of ——. E. Grimpe. G.P. 357,484, 11.12.19.

ELLULOID photographic films are steeped in a bath ontaining *e.g.*, 85 pts. by volume of water-glass, —13 pts. of glycerin, and 2–5 pts. of gum arabic, ith or without the addition of powdered mica. —L. A. C.

XXII.—EXPLOSIVES; MATCHES.

and test for detonators; Modifications of the ——. W. M. Dehn. Chem. and Met. Eng., 1922, 27, 784—787.

A MODIFIED apparatus was employed for carrying out his test. 500 g. of standard sand was used so that nough should be present to enable the detonator o exert its maximum crushing effect. The sand used was rounded and sand recovered from one test was not used again. The confinement of the sand was effected by a heavy weight of special design, and the whole was tamped down to a maximum compression, the detonator being in the centre of a ball-like mass of sand. Only sand passing a 30-mesh and remaining on a 100-mesh sieve was weighed, that passing 100-mesh being calculated by difference. Different weights of the same detonating substance, or indeed equal volumes of the same substance differing in density of packing did not exert crushing effects on sand directly proportional to the weights used. Comparison of the strengths of different detonators as determined by the sand test are therefore only approximate.—H. C. R.

Chlorate explosives; Toxicity of the fumes from ——. H. Kast and A. Haid. Z. ges. Schiess- u. Sprengstoffw., 1922, 17, 145—149.

A SMALL quantity of carbon monoxide is produced in the detonation of chlorate explosives even when sufficient oxygen is present for complete oxidation. This behaviour is shared by ammonium nitrate explosives. If the fumes are collected, they may be found to contain 0·1% of carbon monoxide, which might under unfavourable circumstances exercise a toxic action. Oxides of nitrogen are formed in small quantity during the combustion of chlorate explosives containing nitro-compounds, and the powerful toxic action of these gases might affect the respiratory organs in localities where a local concentration of the fumes had occurred. The effect would be intensified by the irritating action of the alkali chlorides and soot in suspension in the fumes. The fumes of burning ammonium nitrate explosives and of nitro-compounds are very much more toxic than those of chlorate explosives owing to the presence of greater quantities of nitric oxide, but chlorate explosives are much more prone to burn instead of detonate than either ammonium nitrate or nitro-compounds.—H. C. R.

Patents.

Detonating compositions for detonators or primers; Manufacture of ——. E. von Herz. E.P. 187,012, 11.7.21.

A DETONATING mixture is composed of lead azide and lead trinitroresorcinate, the two substances being precipitated together, from solution, or either salt being separately precipitated in the presence of the other. Thus the mixture may be precipitated by causing a solution of sodium azide and magnesium trinitroresorcinate to flow slowly into a solution of lead nitrate slightly acidified with acetic acid at a temperature not below 60° C. Preferably lead trinitroresorcinate is suspended in an aqueous solution of lead acetate and a dilute solution of sodium azide added at atmospheric temperature. The proportions employed are preferably such as to yield a mixture containing about 40—50% of lead azide. —J. S. G. T.

Explosive. W. Rintoul, T. J. Nolan, and O. W. Stickland, Assrs. to Nobel's Explosives Co., Ltd. U.S.P. 1,392,851, 4.10.21. Appl., 19.10.20.

See E.P. 166,277 and 166,502 of 1919; J., 1921, 639A.

XXIII.—ANALYSIS.

Brass weights; Protection of ——. J. J. Manley. Phil. Mag., 1922, 44, 948—950.

THE method introduced by Faraday for the protection of iron from rust, has been employed for protecting brass weights. A satisfactory method of procedure is to cover the weight with a thin film of linseed oil, and heat in a "vitreosil" crucible or a muffle furnace until the weight assumes a golden tint. The protecting film which is formed is tough and may be polished. The weight of 1 sq. cm. of normal film is 0·00005 g.—W. E. G.

Cold; Generation and utilisation of ——. [*Measurement of low temperatures.*] C. R. Darling. Faraday Soc., 16.10.22. [Advance proof.]

THE thermal junction method of low temperature measurement is advocated because of the quick response such instruments give to temperature changes and their adaptability for use in confined spaces. The recent checking of an old instrument made of a flexible couple of Hoskins' alloy and capable of reading to −200° C. has shown that such instruments maintain their accuracy. Resistance thermometers are recommended as the best available method of temperature recording in a cold storage installation, since several instruments can be placed at different points in a factory and coupled through a switchboard with a common indicator.—S. G. U.

Thermometric lag with especial reference to cold storage practice. E. Griffiths and J. H. Awbery. Faraday Soc., 16.10.22. [Advance proof.]

EXPERIMENTS were carried out with a mercury glass themometer with wooden sheath and lagging, a spirit thermometer, a mercury in steel thermometer, and a resistance thermometer, in order to determine the magnitude of some possible sources of error, when mercury or spirit thermometers are removed from the hold to the deck of a ship for reading, and to obtain information regarding the error introduced by the time lag when the cold storage temperature is rapidly changing. After calibration the time lag was determined by inserting the thermometers in a carefully insulated cubical box (2 ft. edge) within which was a rectangular spiral of iron piping through which circulated expanded ammonia to maintain a constant temperature, recorded by a freely suspended thermo-junction. From observations taken curves connecting temperature above surroundings and time were plotted. From these a second set of curves, connecting the logarithm of temperature excess above that of the enclosure and time were derived. These proved to be straight lines and the slopes denoted by $-1/L$ gave the relative time lags of the thermometers. L is a convenient constant, the value of which, if known for a particular thermometer is sufficient to determine the behaviour of that instrument under any circumstance as regards time lag. When the thermometer is introduced into an enclosure the temperature of which is changing uniformly this

thermometer records the temperature which existed in the chamber L minutes previously.
—S. G. U.

Colorimetric researches; Application of coloured glasses instead of liquids in ——. K. Sondén. Ark. Kem. Min. Geol., 1922, **8**, [7], 1—10.

Combinations of coloured glasses may be conveniently used as standards in colorimetry. The coloured glasses are suitably prepared by dyeing the gelatin film on a photographic plate from which the silver has been removed by treatment with thiosulphate.—W. O. K.

Supersaturation; Quantitative analysis by measurement of the degree of ——. E. F. Höppler. Chem.-Zeit., 1922, **46**, 957—958.

The time elapsing between the addition of a reagent and the formation of a precipitate or coloration can be utilised as an approximate quantitative measure of traces of substances in solution. The method is particularly applicable to water analysis. SO_3 and CaO can be estimated in this way between the dilutions of 2·3 and 100 mg. per litre, N_2O_3 can also be estimated by this means when in not greater concentration than 0·5 mg. per litre.—H. C. R.

Precipitation analysis; Application of conductometric methods to ——. V. Titrations with barium salts. I. M. Kolthoff. Z. anal. Chem., 1922, **61**, 433—448.

Sulphates may be titrated conductometrically with barium chloride rapidly and exactly if some alcohol is added to the solution. Mineral acids and iron, aluminium, and calcium salts interfere but nitrates do not. The method is inapplicable to the determination of sulphates in drinking water. Carbonates, chromates, oxalates, tartrates, citrates, and malates in the presence of sufficient alcohol, are capable of exact conductometric titration with barium chloride but not phosphates, pyrophosphates, succinates, benzoates or salicylates. (*Cf.* J.C.S., Dec.)—A. R. P.

Calcium; Volumetric estimation of ——. A. Vürtheim and G. H. C. Van Bers. Chem. Weekblad., 1922, **19**, 450—452.

After addition of excess of ammonium oxalate and ammonia, the solution is filtered and an aliquot part titrated with permanganate; blank titrations must be carried out, as ammonium oxalate solutions vary rapidly. The results agree well with gravimetric estimations. (*Cf.* J.C.S., Dec.)—S. I. L.

Magnesia; Separation of ferric oxide and alumina from —— by the nitrate method. A. Charriou. Comptes rend., 1922, **175**, 693—695. (*Cf.* J., 1922, 81 A, 351 A.)

Ferric oxide or alumina may be quantitatively separated from magnesia by precipitation with ammonia solution in presence of ammonium nitrate. The precipitate is dried at a temperature below 150° C., so that the nitrate is not decomposed, then boiled with ammonium nitrate solution, and finally treated with boiling water. The author states that no trace of aluminium or iron is found in the solution after treating with the nitrate. It is difficult to remove the oxides from the crucible for weighing, and a tared crucible should therefore be used. The magnesium may be estimated in the solution and washings.—H. J. E.

Nickel; Gravimetric determination of —— as nickel dioxide. W. Vaubel. Chem.-Zeit., 1922, **46**, 978.

Nickelous hydroxide is precipitated from the solution with sodium hydroxide, collected, washed, and ignited. The ignited precipitate is further washed until free from alkali metals, dried, and dissolved in nitric acid. The excess of nitric acid is evaporated and the crucible heated for 30 mins. in an air bath at 280°—330° C. Pure black nickel dioxide is left. The oxide, Ni_2O_3, does not exist, the known oxides of nickel being NiO, Ni_3O_4 and NiO_2.—H. C. R.

Nickel; Electrometric determination of —— with silver nitrate. E. Müller and H. Lauterbach. Z. anal. Chem., 1922, **61**, 457—464.

Nickel may be determined by adding a known amount of standard potassium cyanide solution to the neutral nickel solution and determining the excess by conductometric titration with silver nitrate whilst vigorously agitating the solution. The results agree closely with those obtained by Moore's method (Chem. News, 1895, **72**, 92; Z. anal. Chem., 1909, **48**, 778). (*Cf.* J.C.S., Dec.)—A. R. P.

Arsenic, antimony and tin; Separation of ——. F. L. Hahn. Z. anorg. Chem., 1922, **123**, 276.

The separation of antimony by oxidation to pyroantimonate (*cf.* Hampe, J., 1895, 302) can be employed for the estimation of antimony in the presence of arsenic and tin.—W. T.

Analytical chemistry; Contradictions and errors in ——. I. Precipitation of aluminium by thiosulphate and its separation from iron. II. Ageing of volumetric thiosulphate solutions. F. L. Hahn, G. Leimbach, and H. Windisch. Ber., 1922, **55**, 3161—3165.

The precipitation of aluminium by thiosulphate under the customary conditions is far from complete; it is almost quantitative when the solutions are boiled for a short time, and the aluminium still in solution is precipitated by bases. An almost complete separation of aluminium from iron can be effected if a very weak base, preferably phenylhydrazine, is used. The addition of a very small amount of alkali enables thiosulphate solutions to be preserved without alteration in strength from the first day. The change which they otherwise suffer appears to be caused by the faintly acid reaction of distilled water; it certainly does not involve the formation of sulphite or sulphide.
—H. W.

Copper; Catalytic reaction for the detection and a method for the estimation of the smallest traces of ——. F. L. Hahn and G. Leimbach. Ber., 1922, **55**, 3070—3074.

When a solution of a ferric salt is added to a solution of sodium thiosulphate a dark violet coloration is developed which gradually disappears as the ferric salt becomes reduced and the sodium thiosulphate is converted into tetrathionate. The reaction is greatly accelerated by the presence of copper salts and its completion can be made more obvious by the addition of ammonium thiocyanate to the mixture; the latter substance has also the advantage of retarding the action. The following solutions are required: copper sulphate solution (3·9 g. of the pentahydrate per litre, of which 1 c.c. is diluted to 1 litre before use); ferric solution (5 g. of iron alum and 25 c.c. of 2 *N* hydrochloric acid per litre); 5 M ammonium thiocyanate solution; *M*/15 sodium thiosulphate solution. For the recognition of the minutest traces of copper, two litres of the iron solution should be mixed with 10—20 c.c. of thiocyanate solution; for the estimation of larger amounts, more thiocyanate (up to 200 c.c.) may be used. For the estimation a solution of the substance under investigation (as neutral as is possible) is placed in a beaker of about 500 c.c.

capacity and known quantities of the copper solution are brought into a series of similar beakers. The solutions are made up to a fixed volume with distilled water and to each is added 100 c.c. of the iron thiocyanate solution. Simultaneously (by means of a row of test tubes fastened to a rod which can be rotated horizontally) 25 c.c. of sodium thiosulphate solution is added to each beaker and the contents are well mixed. The times required for decolorisation (conveniently 10—20 mins.) are then compared. The velocity of the reaction depends so largely on the ratio of the concentrations, iron: thiocyanate: thiosulphate, on the degree of acidity and the temperature that it is scarcely possible at present to indicate definite intervals of time for definite quantities of copper. It is necessary to observe the progressive decolorisation in the solution under investigation and in solutions of known copper content simultaneously and to use a sufficient volume of solution (about 100 c.c.) to avoid the effect of local variations in temperature. The smallest amount of copper which can be detected with certainty under these conditions is 0·2 μg. A similar effect on the course of the reaction has not been observed with any other substance yet investigated. Acceleration is caused by relatively large amounts of platinum, but the effect is so little marked that a confusion with copper is impossible. Aluminium, zinc, nickel, and arsenic, in particular, retard the action especially in strongly acid solution. If such metals are to be investigated with regard to their copper content, it is essential that an equal weight of "foreign" metal should be added to the comparison solutions; in this manner, the presence of 0·001% of copper in nickel can be detected with rapidity and certainty.—H. W.

Bismuth; Estimation of —— as metal. A. Kurtenacker and F. Werner. Z. anorg. Chem., 1922, **123**, 166—170.

The authors found that dissolving in ferric salt and titrating the ferrous salt produced by potassium permanganate was a reliable method for the estimation of metallic bismuth, the reaction being $3Fe^{\cdots}+Bi=Bi^{\cdots}+3Fe^{\cdot\cdot}$. Ferric chloride is more suitable than the sulphate. Reduction of bismuth nitrate by formaldehyde, hypophosphorous acid, and alkali stannite gave results 5% too low. The weight of precipitate (Bi) was a fraction of 1% too high. The low result by titration is due to a small amount of bismuthous oxide being found in the precipitate ($Bi^{\cdot\cdot}+Fe^{\cdots}=Bi^{\cdots}+Fe^{\cdot\cdot}$), this requiring only one-third of the amount of iron required by the metal. Conditions for complete reduction to the metal could not be found.—W. T.

Sulphuric acid; Determination of —— as barium sulphate. Evidence of the existence of a complex barium sulphuric acid. D. Balarew. Z. anorg. Chem., 1922, **123**, 69—82.

The sources of error in the estimation of sulphuric acid as barium sulphate are given as occlusion of salts, *e.g.* barium chloride, by the precipitate, occlusion of mother liquor, and the formation of the complex ion $[Ba_5(SO_4)_6]$, the last-named being the chief source of error. The author isolated the potassium salt of this complex anion $[Ba_5(SO_4)_6]K_2$. Error due to this cause is reduced to a minimum by precipitating slowly from a dilute, boiling solution acidified with hydrochloric acid. Crystals of precipitated barium sulphate have various forms; the prismatic form corresponds to the simple salt. The chlorine content of barium sulphate is not caused by the salt, $BaClSO_4,BaCl$.—W. T.

Phosphoric acid; Use of benzidine in the detection of ——. F. Feigl. Z. anal. Chem., 1922, **61**, 448—454.

The solution is treated with ammonium molybdate solution and, whether a precipitate forms or not, filtered through a close-textured ashless filter paper. The paper is treated with a solution of benzidine hydrochloride containing acetic acid and then held over an ammonia bottle. If phosphoric acid is present a blue to almost black colour is produced which is apparent even when the original solution contains only 1 part of P_2O_5 in 300,000 of water. The method serves to distinguish phosphomolybdates from arsenomolybdates and from molybdic acid, both of which may be co-precipitated under certain conditions. (*Cf.* J.C.S., Dec.)—A. R. P.

Phosphoric acid; Iodometric micro-estimation of ——, and of phosphorus in organic compounds. O. Svanberg, K. Sjöberg, and G. Zimmerlund. Ark. Kem. Min. Geol., 1922, 8, [10], 1—17.

An improvement on Neumann's method for the micro-estimation of phosphorus is described, in which the phosphorus is precipitated as ammonium phosphomolybdate, and the nitrogen in the precipitate is determined by Bang's micro-Kjeldahl method, the excess of acid remaining after absorption of the ammonia being estimated by adding excess of potassium iodide and potassium iodate, and titrating the liberated iodine with thiosulphate. 0·05—1·00 mg. of phosphorus may be estimated to within 2—3%.—W. O. K.

Boric acid; Titration of ——, in presence of phosphoric acid. I. M. Kolthoff. Chem. Weekblad, 1922, **19**, 449—450.

The phosphoric acid is titrated first with sodium hydroxide in presence of excess of sodium citrate, using phenolphthalein as indicator. Mannitol is then added, and the boric acid titrated in the usual way; the pink coloration must persist for 3 minutes. Calcium and magnesium do not interfere. (*Cf.* J.C.S., Dec.)—S. I. L.

Nitrous acid; Titration of —— alone and in the presence of arsenious acid. A. Klemenc and F. Pollak. Z. anal. Chem., 1922, **61**, 448—454.

An excess of potassium permanganate solution and sulphuric acid is placed in a stoppered flask carrying two tubes with stopcocks, one tube leading below the surface of the liquid. The flask is filled with carbon dioxide, then partially exhausted, and cooled in ice. The neutral nitrite solution is run in and the contents of the flask are shaken and slowly heated to 40° C. The excess of permanganate is determined by titration with oxalic acid. Under these conditions arsenious acid is quantitatively oxidised to arsenic acid. If present in the solution it may be determined in another portion by titration with iodine in the presence of excess of sodium bicarbonate. Nitrous acid is then found by difference. (*Cf.* J.C.S., Dec.)—A. R. P.

Gases; Portable apparatus for the analysis of [determination of carbon dioxide in] —— by the dry method. H. Strache and K. Kling. Feuerungstech., 1922, **11**, 13—15.

A double-acting pump is arranged to deliver a fixed quantity of gas for analysis into an absorption flask of constant volume, after removing an equal volume of gas free from carbon dioxide. The carbon dioxide is removed from the sample by means of solid potash, and the fall in pressure gives a measure of the amount present. The walls of the flask are kept moist to prevent reduction of pressure due to absorption of moisture. The apparatus is enclosed in a small box which is quite portable. Only one tap is used, this having three sets of borings, controlling the flow of gas through nine leading tubes. Each analysis takes from 10 to 20 secs.—W. P.

Gas analysis; Apparatus for exact ——. K. A. Schaller and W. Berndt. Chem.-Zeit., 1922, **46**, 972—973.

The apparatus consists of a manometer, a measuring tube immersed in a water jacket with air agitation, and a detachable absorption vessel with its own adjustable mercury reservoir. The passage of the mercury from the manometer into the measuring tube is prevented by a special U-tube containing at its lowest point either a constriction or a throttle-cock. All the operations of gas analysis can be carried out in this apparatus except explosions, for which the absorption vessel is replaced by a eudiometer. The procedure for determining carbon dioxide, heavy hydrocarbons, oxygen, carbon monoxide, and the combustion of hydrogen, methane, and ethane is described. —H. C. R.

Analytical notes. III. [Detection of urea, and determination of proteolytic enzymes.] L. Pincussen. Biochem. Zeits., 1922, **132**, 242—244.

Urea is best detected in a fluid free from ammonia by addition of urease at p_H 7·0—7·2, keeping at 55° C. for 15 minutes, then adding two drops of saturated sodium carbonate solution and detecting the liberated ammonia by litmus paper. If the liquor contains ammonia originally it is removed by shaking with permutite (0·2 g. per c.c.). A quantitative method for estimating proteolytic enzymes is described which depends on the micro-Kjeldahl estimation of the non-protein nitrogen formed by digestion. Unchanged protein is removed by colloidal iron.—H. K.

Bingham viscosimeter; Drainage error in the ——. W. H. Herschel. J. Ind. Eng. Chem., 1922, **14**, 724.

An instrument similar to the Bingham viscosimeter was so arranged that the drainage error could be measured by calibration with liquids of various viscosities, and the results are embodied in a graph, from which correction factors may be taken to correct the results obtained with liquids having higher viscosities than the calibrating liquid. The time of flow to render the drainage error negligible is also shown.—H. M.

Patents.

Gas analysing apparatus. Svenska Aktiebolaget Mono. E.P. 162,249, 19.4.21. Conv., 23.4.20.

In a gas analysing apparatus of the type described in E.P. 103,812 (J., 1918, 447 A), wherein two or more series of analyses are carried out and a determination of one or more constituents of the mixture included in all the analyses, means are provided for obtaining a single common record of the successive alternate analyses, the record consisting of a number of adjacent lines extending in the same direction. Thus the device may be applied to the analysis of smoke in such manner that in every alternate analysis the percentage of carbon dioxide is recorded, while in the others, the percentage of carbon dioxide, carbonic oxide, hydrocarbons and hydrogen is recorded.—J. S. G. T.

Pyrometer; Optical —— for measuring high temperatures. M. Lockhoven. G.P. 357,975, 5.12.20.

Rays of light from a sheet of refractory material suspended at a place at which it is desired to measure the temperature are transmitted through a long tube to a polariser and thence through a plate of quartz or other optically-active material to an analyser. The degree of rotation of the plane of polarisation of the transmitted light affords a means of estimating the temperature of the sheet of refractory material.—L. A. C.

Calorific value of gases; Method and apparatus for determining the ——. C. H. Lanphier. U.S.P. 1,432,472, 17.10.22. Appl., 23.6.19.

See E.P. 184,025 of 1921; J., 1922, 791 A

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given; they are on sale at 1s. each at the Patent Office, Sale Branch, Quality Court Chancery Lane, London, W.C. 2, 15 days after the date given.

I.—GENERAL; PLANT; MACHINERY.

Applications.

Barbet et Fils et Cie. Distillation and rectification. 31,846. Nov. 21. (Fr., 21.11.21.)

Bewsher. Valves for acids etc. 31,329. Nov. 16.

Bradley Pulverizer Co. Grinding-mills. 30,975–6. Nov. 16. (U.S., 16.11.21.)

Braithwaite and Co., and Smith. Crystallisation of matter in solution from liquids. 31,877–8. Nov. 22.

Farbw. vorm. Meister, Lucius, u. Brüning. Apparatus for absorbing gases etc. by means of charcoal. 31,373. Nov. 16. (Ger., 30.12.21.)

Fraisse. Concentrating liquids by evaporation. 31,372. Nov. 16. (Fr., 5.12.21.)

Fullerton, Hodgart, and Barclay, and Holmes. Evaporators etc. 31,320. Nov. 16.

Gas Light and Coke Co., Shannan, and Siderfin. Conduct of chemical reactions involving use of gases etc. under pressure. 31,596. Nov. 18.

Gas Light and Coke Co., Shannan, and Siderfin. Crystallisation. 31,597. Nov. 18.

Harper and Lamplough. Retorts or stills. 31,156–7. Nov. 14.

Jung. Filter etc. press. 32,160. Nov. 24. (Ger., 19.5.22.)

Kilner and Stevens. Separation and storage, conveyance of solids and liquids, and production of composite fuel. 31,126. Nov. 14.

Lacy. Apparatus for recovering solvents by distillation. 31,901. Nov. 22.

Laing and Nielsen. 31,807. *See* II.

Lancaster, Langford, and Winget, Ltd. Machine for mixing or washing viscous, plastic, etc. substances. 31,719. Nov. 20.

Lockhart. Centrifugal separators. 32,111. Nov. 23.

Lockhart. Hydraulic separators. 32,112. Nov. 23.

Monson. Treatment of liquid and fatty substances. 31,458. Nov. 17.

Morgan, and Thermal Industrial and Chemical Research Co. Method of distillation. 31,012. Nov. 13.

Ward. Filtering liquids etc. 31,933. Nov. 22.

Wood. Drying-apparatus. 31,785. Nov. 21.

Complete Specifications Accepted.

13,161 (1921). Nitrogen Corp. Production of catalysts. (163,046.) Nov. 22.

16,547 (1921). Rigby. Heating or cooling liquids or admixed solids and liquids in evaporative or like treatment. (188,703.) Nov. 29.

18,395 (1921). Plauson's (Parent Co.), Ltd. (Plauson). Filter press. (188,362.) Nov. 22.

19,240 (1921). Sutcliffe and Raper. Recovery of gases or vapour from charcoal etc. (188,723.) Nov. 29.

21,926 (1921). Lambert. Manufacture of absorbents or adsorbents of condensible gases and vapours. (188,786.) Nov. 29.

22,703 (1921). Stehmann. Rotary calcining furnaces. (188,424.) Nov. 29.

26,347 (1921). Seedorff, Barfred, and George. Tunnel furnaces or kilns. (188,488.) Nov. 22.

30,874 (1921). Timm. Filtering apparatus. (188,539.) Nov. 22.

301 (1922). Frankenberger. Dry grinding cylinders. (188,581.) Nov. 22.

23,911 (1922). Rigby. Preheaters for evaporators etc. (188,623.) Nov. 22.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Applications.

Algem. Norit Maatsch. and General Norit Co. Production of decolorising-carbon. 31,686. Nov. 20. (Holland, 19.11.21.)

Amato. Treatment of petroleum etc. 32,059. Nov. 23.

Appleby and Bentley. Gas producers, retorts, etc. 31,122. Nov. 14.

Davidson. Gas purification. 32,317. Nov. 25.

Dunstan and Thole. Utilisation of alcohol in production of liquid fuel. 31,314. Nov. 16.

General Norit Co. and N. V. Algem. Norit Maatsch. Apparatus for revivifying finely-divided decolorising-carbon etc. 31,008. Nov. 13. (Holland, 14.11.21.)

Goldman. Producing carbon-black etc. 31,004. Nov. 13.

Haller and McLaren. Utilising waste gases from furnaces. 31,940. Nov. 22.

Harper and Lamplough. 31,156–7. *See* I.

Kilner and Stevens. 31,126. *See* I.

Koppers. Apparatus for degasifying or distilling gas from non-coking bituminous materials at low temperatures. 31,962. Nov. 22.

Laing and Nielsen. Rotary retorts, kilns, etc. 31,807. Nov. 21.

Levy. 31,235. *See* XXIII.

Loriette. Production of liquid fuel mixtures with alcohol as basis. 31,786. Nov. 21. (Fr., 21.11.21.)

Lucas, and V. L. Processes, Ltd. Treatment of hydrocarbons and their derivatives. 32,219. Nov. 24.

McLaren, Thomas, and Powdered Fuel Plant Co. Drying pulverulent fuel. 31,231. Nov. 15.

Masterman and Weygang. 31,172. *See* XII.

Robertson (Power Specialty Co.). Distilling oil. 32,108–9. Nov. 23.

Simmance. 31,235 and 31,450. *See* XXIII.

Wilkinson. Chemical process for facilitating combustion of coal dust in furnaces etc. 32,120. ov. 24.

Complete Specifications Accepted.

13,758 and 20,968 (1921). Plauson's (Parent Co.), Ltd. (Plauson). Extraction of hydrocarbons from shale, wood, etc. (188,686.) Nov. 29.

14,153 (1921). Bergh and Larsson. Furnaces for utilising bituminous shale by distillation and subsequent combustion. (188,693.) Nov. 29.

16,806 (1921). Siemens Bros. and Co., and Le Maréchal. *See* X.

18,092 (1921). Burnie (Bitumul-Matita Soc. Anon. Romana). Manufacture and treatment of bitumen. (188,354.) Nov. 22.

18,441 (1921). Technical Research Works, and Pelly. Lubricants. (188,364.) Nov. 22.

21,321 (1921). Walker. Fractional distillation of crude naphtha. (188,402.) Nov. 22.

22,460 (1921). Hart. Production of carbon. (188,807.) Nov. 29.

25,181 (1921). Nicholls and Brown. Manufacture of liquid fuel from peat. (188,469.) Nov. 22.

28,900 (1921). Hovey. Obtaining light hydrocarbon distillates from heavier hydrocarbons. (188,928.) Nov. 29.

34,846 (1921). China and others. *See* III.

4745 (1922). Egeling. Saturators for use in recovering salts from gases of dry distillation. (175,649.) Nov. 22.

5118 (1922). Beswick and Rambush. Manufacture of producer-gas and recovery of high yields of by-products. (188,607.) Nov. 22.

19,703 (1922). Elektrizitätswerk Lonza. *See* XX.

III.—TAR AND TAR PRODUCTS.

Applications.

Lucas and others. 32,219. *See* II.

Vivian. Treatment of tar etc. 32,174. Nov. 24.

Complete Specification Accepted.

34,846 (1921). China, and Burt, Boulton, and Haywood. Apparatus for distilling coal tar, petroleum, etc. (188,575.) Nov. 22.

IV.—COLOURING MATTERS AND DYES.

Applications.

Bloxam (Chem. Fabr. Griesheim-Elektron). Manufacture of azo dyestuffs. 32,080. Nov. 23.

Gas Light and Coke Co., Lewcock, and Voss. Manufacture of sulphurised dyes. 31,595. Nov. 18.

Holliday and Co., and Clayton. Colouring-matters. 31,413 and 31,427. Nov. 17.

Holliday and Co., and Stokes. Colouring-matters. 31,406. Nov. 17.

Imray (Soc. Chem. Industry in Basle). Manufacture of azo dyestuffs. 31,254. Nov. 15.

Complete Specification Accepted.

29,289 (1921). British Dyestuffs Corp., and Wyler. Manufacture of phenylglycine compounds. (188,933.) Nov. 29.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Applications.

Bacon and Sindall. Sizing and hardening paper etc. 31,469. Nov. 17.

Göransson. 31,331. *See* XV.

COMPLETE SPECIFICATIONS ACCEPTED.

18,501 (1921). Wade (Barrett Co.). Manufacture of fibrous material. (166,886.) Nov. 29.

23,354 (1921). Steinhilber. Recovery of cellulose from reeds etc. (188,828.) Nov. 29.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

APPLICATIONS.

Ashworth. Machines for dyeing etc. yarns in hanks etc. 31,198. Nov. 15.

British Dyestuffs Corp., Green, and Saunders. Dyeing artificial silk etc. 31,382. Nov. 16.

British Dyestuffs Corp., Green, and Saunders. Printing fabrics containing fibres of acetate silk. 31,383. Nov. 16.

Moseley. Agents for scouring, bleaching, dyeing, etc. 31,078. Nov. 14.

COMPLETE SPECIFICATIONS ACCEPTED.

22,512 (1921). Deutsche Gold- u. Silber-Scheideanstalt, and Schaidhauf. Bleaching textile fibres. (188,811.) Nov. 29.

7884 (1922). Bloxam (A.-G. f. Anilinfabr.). Dyeing furs, hairs, etc. (189,046.) Nov. 29.

10,913 (1922). Bloxam (A.-G. f. Anilinfabr.). Dyeing furs, skins, hairs, feathers, etc. (189,054.) Nov. 29.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

APPLICATIONS.

Blattner (Grouchkine). Manufacture of caustic alkali. 31,370. Nov. 16.

British Cyanides Co., and Rossiter. Manufacture of caustic alkali and metallic chlorides. 32,294. Nov. 25.

Cocksedge. Production of a sodium compound. 31,184. Nov. 15.

Daniels. Manufacture of crystallised carbonate of soda. 30,964. Nov. 13.

Fairweather (Federal Phosphorus Co.). Production of phosphoric acid and ferrophosphorus. 31,973. Nov. 22.

Jackson (Koppers Co.). Treatment of alkali salt solutions. 31,848. Nov. 21.

Lever Bros., Tainsh, and Thomas. Manufacture of caustic soda. 31,516. Nov. 17.

Lever Bros., Thomas, and Williams. Manufacture of caustic soda. 31,517. Nov. 17.

Llewellyn, Spence, and Spence and Sons. Production of aluminous compounds. 31,211. Nov. 15.

Nicholson. Neutralising ammonium sulphate. 32,134. Nov. 24.

Thompson (Atack and Jacobson). Manufacture of aluminium chloride. 30,933. Nov. 13.

COMPLETE SPECIFICATIONS ACCEPTED.

13,162 (1921). Nitrogen Corp. Preparation of mixtures of nitrogen and hydrogen suitable for the production of ammonia. (163,047.) Nov. 29.

13,813 (1921). Nitrogen Corp. Production of hydrogen or mixtures of nitrogen and hydrogen. (163,703.) Nov. 29.

16,743 (1921). Mau. Manufacture of concentrated hydrogen peroxide solution. (167,156.) Nov. 29.

22,393 (1921). L'Air Liquide Soc. Anon. Synthesis of ammonia. (171,970.) Nov. 22.

23,740 (1921). L'Air Liquide Soc. Anon. Synthesis of ammonia. (171,972.) Nov. 29.

24,586 (1921). Plauson's (Parent Co.), Ltd. (Plauson). Obtaining alkali salts from felspar and like minerals. (188,454.) Nov. 22.

25,219 (1921). Plauson's (Parent Co.), Ltd. (Plauson). Manufacture of colloidal sulphur. (188,854.) Nov. 29.

25,937 (1921). Wetzlar (Pauling). Converting into sulphates by means of nitric acid, metals and alloys insoluble or only gradually soluble in sulphuric acid. (188,868.) Nov. 29.

27,188 (1921). West, Jaques, and Tully. Manufacture of hydrogen or gases rich in hydrogen. (188,494.) Nov. 22.

31,941 (1921). Aktieselskabet Labrador. Precipitation of iron in mineral acid alumina solutions. (172,944.) Nov. 29.

32,859 (1921). Bichowsky and Harthan. Production of titanium nitrogen compounds. (188,558.) Nov. 22.

712 (1922). Royston. Apparatus for neutralising sulphate of ammonia in wet state. (188,587.) Nov. 22.

4745 (1922). Egeling. *See* II.

21,997 (1922). Ephraim. Production of sulphides and hydrosulphides of the alkali metals. (184,795.) Nov. 29.

VIII.—GLASS; CERAMICS.

APPLICATIONS.

Heathcote and Mawson. Enamel. 32,261. Nov. 25.

Salerni. Abrading materials. 32,310. Nov. 25.

COMPLETE SPECIFICATIONS ACCEPTED.

19,149 and 19,851 (1921). Parsons, Peddle, and Duncan. Manufacture of optical glass. (188,721.) Nov. 29.

24,466 (1921). British Thomson-Houston Co. (General Electric Co.). Manufacture of silica glass. (188,451.) Nov. 22.

IX.—BUILDING MATERIALS.

APPLICATIONS.

Cloke. Compound for surfacing roads etc. 31,970. Nov. 22.

Commin and Hughes. Asbestos compositions. 31,020. Nov. 13.

Pearlman. Composition for coating stonework. 31,217. Nov. 15.

Spence and Wake. Binding-material for road-making etc. 31,819. Nov. 21.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

APPLICATIONS.

Barron, Halliwell, and Hindley. Cementation of iron or steel etc. articles. 31,180. Nov. 15.

Blower. Brazing flux. 31,553. Nov. 18.

Campbell. Production of steel alloys having low content of carbon. 31,011. Nov. 13.

Carbonex, Ltd., and Rodwell. Materials for hardening iron or steel. 31,939. Nov. 22.

Coley. Apparatus for reducing ores or oxides. 31,321. Nov. 16.

Coley. Apparatus for manufacture of zinc etc. 31,322. Nov. 16.

Corning Glass Works. Steel for mould materials. 31,146. Nov. 14. (U.S., 17.11.21.)

Diehl. Preparation and smelting of ores, slags, etc. 31,127. Nov. 14.

Edwards. Treatment of oxidised ores etc. 31,685. Nov. 20.

Eureka Metallurgical Co. Flotation processes. 31,843. Nov. 21. (U.S., 4.3.22.)

Eustis. Electrolytic iron. 31,935–6. Nov. 22.

Evans and Hamilton. Manufacture of iron and steel alloys. 31,052. Nov. 14.

Fairweather. 31,973. *See* VII.

Foxley. Alloys. 31,990. Nov. 22.

Golby (Luckenbach Processes, Inc.). Concentration of ores. 30,968. Nov. 13.

Hall and Ransford. Rustproofing metals. 31,599. Nov. 18.

Hall and Ransford. Colouring metal sheets etc. 31,600. Nov. 18.

Sunderland and Sutcliffe. Annealing or heating furnaces etc. 31,539. Nov. 18.

Wagner. Extraction of metals from ores etc. 31,791. Nov. 21.

Complete Specifications Accepted.

16,263 (1921). Bloxam (Aluminium Co. of America). Aluminium alloys. (188,699.) Nov. 29.

16,806 (1921). Siemens Bros. and Co., and Le Maréchal. Production of tungsten and tungsten filaments. (188,706.) Nov. 29.

18,857 (1921). British and Foreign Chemical Producers (Vogel). Pickling iron or iron alloys. (188,713.) Nov. 29.

20,533 (1921). Lenegre. Manufacture of pig iron. (167,475.) Nov. 22.

25,818 (1921). Wetzlar (Pauling). Extraction of metals from ores with nitric acid. (188,865.) Nov. 29.

26,351 (1921). Dubreul. Treatment of compound minerals. (169,990.) Nov. 22.

28,288 (1921). Hess. Recovery of light metals from chippings, residues, and ashes. (175,242.) Nov. 22.

32,002 (1921). Vulkan-Werk Reinshagen u. Co. Blast and cupola smelting furnaces. (183,418.) Nov. 22.

1600 (1922). Harris. Refining lead. (189,013.) Nov. 29.

XI.—ELECTRO-CHEMISTRY.

Applications.

Baumgartner. Electrodes. 31,430. Nov. 17. (Ger., 12.5.22.)

Bianco. Zinc electrolytes. 31,376. Nov. 16. (Austria, 17.1.22.)

Eustis. 31,935–6. *See* X.

Jacobacci. Lead storage batteries. 31,357. Nov. 16.

Rennerfelt. Method of heating materials, and electric furnace therefor. 31,689. Nov. 20.

Complete Specification Accepted.

20,437 (1921). Vesme. Increasing the output of gas from electrolytic apparatus. (188,370.) Nov. 22.

XII.—FATS; OILS; WAXES.

Applications.

Dujardin. 31,632. *See* XIX.

Hughes. Soaps etc. 31,988. Nov. 22.

Masterman and Weygang. Treatment of oils and fats for fuel, soap, etc. 31,172. Nov. 14.

Monson. 31,458. *See* I.

Complete Specifications Accepted.

20,707 (1921). Lobell. Expression of vegetable oils from natural products. (167,487.) Nov. 22.

28,548 (1921). Rocca, Tassy, et de Roux. Extraction of palm kernel oil. (171,680.) Nov. 29.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Applications.

Behr and Co., and Crupi. Waterproof, flexible, abrasive-holding composition etc. 30,984. Nov. 13.

Goldman. 31,004. *See* II.

Goldschmidt A.-G. Production of amorphous finely-divided litharge. 31,248. Nov. 15. (Ger., 15.11.21.)

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Applications.

Bolton and Cuthbe. Manufacture of rubber compounds. 31,837. Nov. 21.

Tanner and Tarver. Products obtained from rubber-containing latex. 31,301. Nov. 16.

Tanner and Tarver. India-rubber products. 32,147. Nov. 24.

Complete Specification Accepted.

25,263 (1921). Hubbard and Crouch. Preparing rubber goods for vulcanisation. (188,856.) Nov. 29.

XV.—LEATHER; BONE; HORN; GLUE.

Application.

Göransson. Manufacture of impregnated leather, pasteboard, etc. 31,031. Nov. 16.

Complete Specifications Accepted.

21,296 (1921). Peradotto. Tanning-apparatus. (167,771.) Nov. 22.

10,913 (1922). Bloxam. *See* VI.

XVII.—SUGARS; STARCHES; GUMS.

Complete Specification Accepted.

33,719 (1921). Reychler. Preparation of solutions of starch. (188,992.) Nov. 29.

XVIII.—FERMENTATION INDUSTRIES.

Applications.

Barbet et Fils et Cie. Production of alcohol. 31,258. Nov. 15. (Fr., 15.11.21.)

Bexon and Church. Brewing. 31,695. Nov. 20.

Lazarus. Extraction of malt for brewing. 31,445. Nov. 17.

Marmite Food Extract Co. (Sevang). Manufacture of yeast. 31,609. Nov. 18.

Marmite Food Extract Co. (Sevang). 32,212. *See* XIX.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

Applications.

Becco Engineering and Chemical Co., and Grant. Treatment of waters containing alkaline bicarbonates etc. 31,977. Nov. 22.

Boby, Boby, and Froude. Water-softener. 32,172. Nov. 24.

Broadbent. Mustard. 31,069. Nov. 14.

Brogdex Co. Treatment of fruit etc. 31,297. Nov. 16. (U.S., 16.11.21.)

Dietrich, Ruppel, and Elektro-Osmose A.-G. Purification of water. 31,698. Nov. 20.

Dujardin. Manufacture of cattle-feeding cakes and oil. 31,632. Nov. 20.

Fairrie. Manufacture of fish meal etc. 31,781–3. Nov. 21.

Gerstenberger. Food product. 31,103. Nov. 14.

Marmite Food Extract Co. (Savang). Manufacture of foodstuffs from yeast. 32,212. Nov. 24.

Munton and Baker, and Townsend. Production of cereal foods. 31,716. Nov. 20.

Complete Specifications Accepted.

13,276 (1921). Mills. Blood coagulation media. (171,959.) Nov. 22.

19,265 (1921). Henneberg. Separation of micro-organisms from liquids. (188,724.) Nov. 29.

21,013 (1921). Leo. Production of a jelly base containing pectin. (188,387.) Nov. 22.

21,828 (1921). Jones and Smith. Antifouling and non-corroding mixtures for treatment of water. (188,778.) Nov. 29.

23,530 (1921). Threlfall and King. Manufacture of products useful as food or medicine. (188,437.) Nov. 22.

31,164 (1921). Activated Sludge, Ltd., and Coombs. Treatment of sewage and like liquid. (188,958.) Nov. 29.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Applications.

Nobel Industries, Ltd. (Du Pont de Nemours and Co.). Production of urea derivatives. 32,095. Nov. 23.

Pereira. Manufacture of dioxyperylene. 31,257. Nov. 15. (Austria, 7.1.22.)

Soc. Chim. Usines du Rhône. Manufacture calcium salt of acetylsalicylic acid. 31,384. Nov. 1 (Ger., [illegible])

Complete Specifications Accepted.

20,758 (1921). Klages, and Saccharinfabr. A.- vorm. Fahlberg, List u. Co. Production of aromat cyan-mercury compounds. (188,376.) Nov. 22.

21,763 (1921). Wolvekamp. Salts of oxidis protalbinic and lysalbinic acids. (188,772.) Nov. 2

29,042 (1921). Napp (Hoffmann-La Roche & Co. Manufacture of a compound of CC-isopropylally barbituric acid. (188,521.) Nov. 22.

19,703 (1922). Elektrizitätswerk Lonza. Manu facture of metaldehyde and obtaining fuel bodi therefrom. (189,074.) Nov. 29.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Application.

Cohen. Phoographic films. 31,262. Nov. 15.

Complete Specification Accepted.

14,031 (1921). Lage. Production of coloure photographs on paper etc. (188,692.) Nov. 29.

XXII.—EXPLOSIVES; MATCHES.

Application.

Pickett. Freeing metal casings of ammunitio from gas fillings, and treatment of such fillings 32,083. Nov. 23.

XXIII.—ANALYSIS.

Applications.

Levy and Simmance. Gas analysis. 31,235 Nov. 15.

Scott, Ltd., and Woodroffe. Apparatus for determining volumetric proportion of gases in mixtures. 32,136. Nov. 24.

Simmance and Wood. Indicating or recording apparatus for gas analysis. 31,450. Nov. 17.

I.—GENERAL; PLANT; MACHINERY.

Colloids; Rôle of the hydrogen ion concentration in the precipitation of ——. H. V. Tartar and Z. J. Gailey. J. Amer. Chem. Soc., 1922, 44, 2212—2218.

Acids cause the precipitation of mastic and gamboge sols at the same hydrogen ion concentration irrespective of the concentration of the colloid; and negative ion is without effect. Potassium and ammonium salts precipitate the sols at the same concentration provided that the hydrogen ion concentration is kept approximately constant. The precipitating values of the salts vary directly as the concentration of the colloid at the same hydrogen ion concentration. The stabilising or peptising effect of the ion bearing a charge similar to that of the colloidal particle is shown to be very limited if it exists at all.—J. F. S.

Volatile substances in air. Fritzmann and Macjulevitsch. *See* XIV.

Patents.

Acids or other liquids; Apparatus for delivering measured quantities by volume of ——. R. Moritz. E.P. 172,011, 22.11.21. Conv., 23.11.20.

An apparatus for measuring and delivering liquids comprises a main measuring vessel within which is a series of smaller measuring vessels of known capacity, open at the top, each fitted with a draw-off tap. The liquid flows from a supply tank through a three-way valve into the bottom of the main measuring vessel and fills the latter and the smaller measuring vessels. The capacity of the main vessel may be adjusted by introducing resistant filling material. By emptying the main measuring vessel through the three-way valve and the desired number of the smaller vessels by means of their respective taps, the required volume of liquid can be run off.—H. R. D.

Tunnel dryer with air circulation. Maschinenfabrik F. Haas Ges. Neuwerk, Assees. of A. Schüssler. E.P. 173,234, 21.12.21. Conv., 23.12.20.

The dryer consists of a tunnel of rectangular cross-section provided with double vertical walls. The spaces between the inner and outer walls on either side of the tunnel are fitted with heating tubes and subdivided by vertical partitions into a number of heating chambers. On the inner wall of each chamber, near the roof of the tunnel, is fixed a fan, and outlet openings are cut in these walls near the floor of the tunnel. The fans and the outlet openings are so arranged that the drying air is admitted at one bottom corner of the drying chamber and is withdrawn by the fan at the opposite top corner. This fan is situated in the next heating chamber and forces the air through its outlet into the next drying chamber. These chambers are formed by a number of trucks which can pass between the inner walls of the tunnel and carry the articles to be dried either on shelves or rods. Tunnels are made to contain from two to five trucks, and the larger the number of trucks the greater is the overlap of the heating chamber over the drying chamber. Air is admitted at the discharging end of the plant and passes through heating and drying chambers alternately until it is discharged at the charging end of the plant.—S. G. U.

Dry kiln. J. F. Hirt. U.S.P. 1,432,248, 17.10.22. Appl., 29.10.21.

A dry kiln has a separate drying chamber and heating chamber, and separate condensing chambers, heating units, intake ducts for fresh air, humidifiers, and exhaust stacks, the four last mentioned being capable of control from outside the apparatus. The heat given off from the top of the drying chamber is transmitted to the main stream of the circulating drying medium, which is then passed over the goods and downwards to the condensing and heating chambers.—B. M. V.

Dryer. J. H. Walsh, Assr. to Johns-Manville, Inc. U.S.P. 1,432,270, 17.10.22. Appl., 27.5.21.

An air-heating chamber and a drying chamber are combined with a heat regenerator which is arranged above the drying chamber with the interposition of a removable screen. The regenerator communicates through passages with an outlet from the drying chamber. Fresh air is drawn into contact with walls of the regenerator outlet passages to preheat it, passes thence to the heating chamber, and is circulated through the chambers, passages, and connexions.—H. H.

Scale in steam boilers, evaporators, economisers, and the like; Method of preventing the formation of ——. K. Schnetzer. E.P. 174,905, 15.12.21. Conv., 29.1.21.

The negative pole of a source of direct current is connected to the boiler or other apparatus at one or more points, and the positive pole of the source of current is left insulated, so that the electrical circuit is never closed.—B. M. V.

Settings for stills and similar purposes. P. Mather. E.P. 186,849, 1.11.21.*

The setting particularly relates to tall vertical stills that it is desired to heat uniformly and in adjustable zones (*cf.* E.P. 175,666; J., 1922, 284 A). The brickwork setting for a vertical cylindrical still, shown in cross-section in the figure, is of substantially the same form as the still and is divided to form a series of annular flues, b, within the still casing, a. A series of liquid fuel or gas burners, k, are arranged on one side of the setting and a vertical flue, s, connected with the annular flues on the other. A layer of non-conducting material, f, is placed between the firebrick lining, g, of the annular flues and the ordinary brickwork backing of the setting, h. The casing of the still opposite the burners is protected by firebrick, o.—T. A. S.

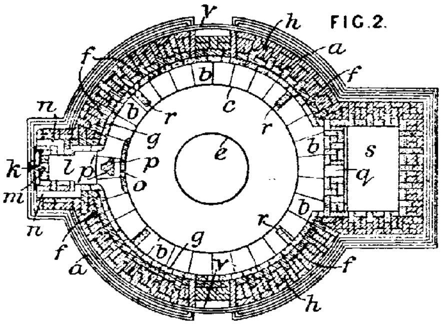

FIG. 2.

Gases, oil vapours, or gaseous mixtures; Method and apparatus for treatment of ——. J. F. Ward, H. Neilsen, and B. Laing. E.P. 186,945, 31.3.21.*

The gas or vapour is introduced tangentially and at high velocity by the pipe, c, into the jacketed chamber, a, fitted with a bottom valve. The cover of the chamber carries a conical deflector, e, a baffle plate, and an outlet pipe, d. Bevel gearing drives a hollow shaft, *f*, bell-mouthed at its lower end, which passes through the centre of the cover. This shaft carries a number of vanes, *g*, and nozzles, *j*, and a perforated basket, *h*. Below the bell-mouth is a nozzle, *m*, coupled to a compressor, *n*, which forces a portion of the gas or other vapour into *f*, thus raising the liquid medium, which may contain solids in mechanical or colloidal suspension, catalysts, or oxidising agents, from the bottom of the chamber, *a*, through the nozzles, *j*. This finely divided liquid having been thrown by centrifugal force against the basket, ultimately falls to the bottom of the chamber and can be again circulated through the nozzles. The gas entering the chamber by *c* is gradually forced downwards until it meets the vanes, *h*, which give it an upward motion through the finely divided liquid in the mixing basket. It then flows into the space above the deflector, where any particles of liquid carried over are caught on the baffle plate, the gas itself entering the outlet pipe. The plant can be used for the hydrogenation of oils or for the desulphurisation, hydrogenation and oxidation of gases or oil vapours. —S. G. U.

---

* The illustrations in the abstracts marked * are reproduced from the Illustrated Official Journal (Patents), by kind permission of the Controller of H.M. Stationery Office.

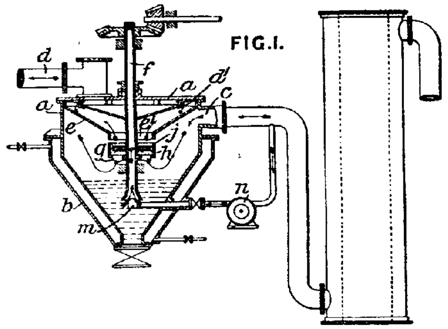

FIG.I.

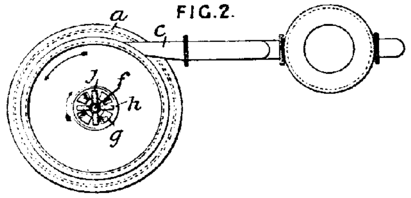

FIG.2.

Chemical apparatus for precipitation purposes. The British Thomson-Houston Co., Ltd. From General Electric Co. E.P. 187,090, 29.8.21.*

The invention relates to a kettle which can be evenly heated and readily kept at a constant temperature, and into which the chemicals required for the reaction can be admitted continuously and from which the precipitate and the mother liquor formed can be withdrawn. Inside a carefully lagged vessel, fitted with a steam coil, pipes for admission and withdrawal of the heating liquid, and a thermometer, is placed a stoneware kettle, 15, having a wooden cover, 28. This cover has a number of openings for the following connexions: a pipe, 29, terminating in a spraying nozzle, through which enters one of the solutions, a pipe (not shown in the figure) through which enters the other solution required for the reaction, a pipe, 33, to admit steam or air for agitating the contents of the kettle, an air-lift, 42, for removing the precipitate and the mother liquor, a fume ejector (not shown), a thermometer pocket, and a device, 47 and 48, for indicating the level of the contents of the kettle. In working the plant a liquid, preferably one which will permit recovery of the contents of the kettle if broken, is introduced into the space between the kettle and the outer vessel and heated by the steam coil. A solution containing, *e.g.*, a soluble tungsten compound is sprayed into the kettle through 31, and the precipitating solution (in this case hydrochloric acid) is admitted by the other pipe, the mixture being agitated by air or heated as found necessary. The precipitate formed and the mother liquor are removed from the bottom of the kettle by the air-lift, the delivery pipe of which is fitted with an air vent, whilst the air, steam, and gases formed during the reaction are removed by the fume ejector. —S. G. U.

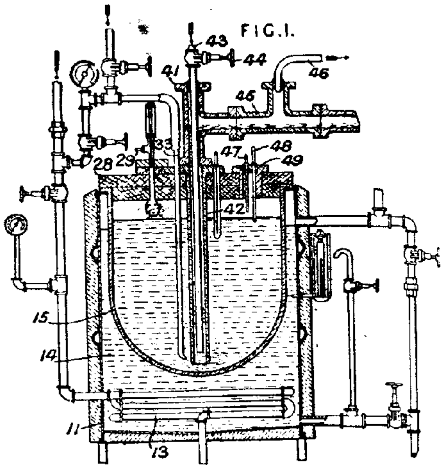

FIG.I.

Heating and cooling of liquids or admixed solids and liquids in evaporative or like treatment thereof; Method of and apparatus for the ——. T. Rigby. E.P. 187,260, 10 and 26.5.21.

In the evaporation of such liquors as brine for the recovery of salt, two or more multiple-effect evaporators are used, the initial and final temperatures in each set being about the same, but the number of stages in the second being less than in the first, so that the temperature range per stage is greater in the second set than in the first; this is to compensate for the raising of the boiling point of the liquor, which is subdivided and passed through the effects of one set in parallel, then, if desired, cooled for crystallising by flashing off vapour, and re-evaporated in the second multiple effect, the liquor again passing through the effects in parallel. The flashing off may be done in stages so as t provide vapour at different temperatures, which i passed to evaporating effects at similar temperatures. The liquors for crystallisation may be removed from the plant to a more suitable location i containers on wheels.—B. M. V.

Evaporating liquids; Method of continuously ——. E. S. Sandberg. U.S.P. 1,433,040, 24.10.2 Appl., 5.9.18.

The liquid to be evaporated is forced under pressu into a heating element where it is heated but whe ebullition is prevented by the pressure. It the passes through a throttled outlet to a low-pressu evaporating chamber, the vapour from which compressed and used as the heating agent. —B. M. V.

vaporation of liquids and drying of substances; Device for the ——. C. R. Mabee. U.S.P. 1,433,141, 24.10.22. Appl., 15.12.13. Renewed 1.3.19.

N evaporating and drying apparatus comprises a bstantially hemispherical heated container, with tary conveyor members arranged adjacent to the terior wall thereof and having a continuous eldable surface of contact with the wall. The all of the container may be maintained at a mperature different from that of the material to treated.—J. S. G. T.

eat-interchanging apparatus. E. L. Pease. E.P. 187,353, 30.7.21.

a heat exchanger embodying plates eccentrically ounted on one or more tubular elements, the lates are so arranged that the longer plate surces are encountered by the fluid to be heated efore the latter comes in contact with the tubular ements conveying the heating fluid. The object to maintain a constant difference of temperature etween the plates and the fluid being heated.
—H. H.

ashing material which has been separated by entrifugal action; Apparatus for ——. Chem. Fabr. Griesheim-Elektron, and F. Sander. E.P. 187,429, 24.9.21.

HE washing liquid, which is specifically lighter han the mother-lye, is supplied through radial ipes to an annular space within the outer all of the drum and bounded on its inner side by ltering material carried by ribs on the drum wall. he lengths of the pipes are so much greater than he thickness of the layer of solids to be washed hat the centrifugal force of the washing liquid vercomes that of the mother-lye, and the washing iquid passes therefore through the solids from the eriphery to the axis of the drum. Instead of the nnular space a series of connected annular pipes ith outlets for the washing liquid may be used, nd these pipes may be so spaced that on removing he outer wall of the drum the washed solids may e removed outwardly by centrifugal action. The over of the drum may be provided with openings rranged in concentric circles, any one of which can e opened or closed as desired to enable the distance t which the separated liquid is discharged and the hickness of the layer of solids to be regulated.
—H. H.

entrifugal separator. A. Gorneau, Assr. to C. and S. Gorneau. U.S.P. 1,432,242, 17.10.22. Appl., 21.1.20.

The basket or separating element of a centrifugal machine is provided with a bearing between its bottom and the bottom of a surrounding container, and with driving means situated entirely outside and above the basket, the driving means being connected to the basket by curved arms forming an arch, like the handle of an ordinary basket.
—B. M. V.

Crushing and grinding mill. F. Wriedt, Assr. to Milo Machinery Co. Proprietary, Ltd. U.S.P. 1,432,046, 17.10.22. Appl., 7.6.22.

A stationary casing or support is provided with a concave cylindrical grinding surface against which work convex grinding elements, which are provided with means for drawing in the material between, and for displacing it transversely to the motion of, the grinding elements.—B. M. V.

Grinding mill. J. B. Sedberry. U.S.P. 1,433,042, 24.10.22. Appl., 4.5.20.

A shaft is journaled within a drum and has one set of grinding elements or beaters fixed to it, while another set of beaters are pivoted on the fixed set. The rigidly fixed and swinging beaters are interchangeable.—B. M. V.

Filter. E. J. Sweetland. U.S.P. 1,432,134, 17.10.22 Appl., 30.4.19.

A movable filter element, mounted within a tank, is provided with means for advancing it step by step.—H. H.

Feeding material to [airtight] treating chambers; System of ——. J. T. Fenton. U.S.P. 1,432,170, 17.10.22. Appl., 29.3.21.

Entrained air is displaced from finely-divided solid material by means of an inert elastic fluid, and the solid is then injected into an apparatus for subsequent treatment by means of a high-pressure jet of elastic fluid.—B. M. V.

Absorption and cooling apparatus. A. B. Jones, Assr. to Clark, MacMullen, and Riley. U.S.P. 1,432,698, 17.10.22. Appl., 18.2.21.

The apparatus is built up of sections each in the form of a hollow body with upper and lower walls inclined downwards. Gas inlet and outlet connexions to the interior of the body are provided; and each section is provided with means for distributing a liquid over its exterior surfaces.
—H. H.

Abstracting heat from fluids; Apparatus for ——. P. R. McCrary. U.S.P. 1,432,705, 17.10.22. Appl., 14.5.19.

A cap is mounted on a shell which is mounted on a base and the parts are held together by a stand-pipe. The shell is provided with adjustable air inlet orifices, and the stand-pipe with adjustable liquid-ejecting orifices. Means are provided for forcing liquid into the stand-pipe, for withdrawing liquid from the base, and for withdrawing air from the shell and a coiled pipe surrounding the stand-pipe within the shell.—H. H.

Acid or alkaline reductions; Process for carrying out ——. W. O. Mitscherling, Assr. to Atlas Powder Co. U.S.P. 1,432,775, 24.10.22. Appl., 21.3.22.

A reducing metallic medium is introduced into a rapidly rotating tube through which is passed the solution to be reduced. The rate of rotation is such as to place the solution under pressure due to centrifugal force.—H. H.

Electric precipitator; Self-cleaning ——. H. F. Fisher, Assr. to Research Corp. U.S.P. 1,433,266, 24.10.22. Appl., 26.11.19.

An electrical precipitator comprises a discharge electrode, a collecting electrode movable in the direction of its length, an abutment in the path of movement, and means for moving the collecting electrode against and away from the abutment.
—J. S. G. T.

Drying apparatus. P. Fleury, Assr. to D. L. Robertson. U.S.P. 1,433,608, 31.10.22. Appl., 21.11.19.

See E.P. 151,488 of 1919; J., 1920, 761 A.

Steam, compressed air and gases; Separating apparatus for [removing water, dust, etc. from] ——. O. Loss, and D. Grove A.-G. E.P. 187,791, 8.9.21.

Sorting, washing or classfying mixed materials of different specific gravities or volumes; Process and plant for ——. M. Croquet. E.P. 187,874, 1.12.21.

Crusher rolls [; Sectional ——]. J. Y. Johnson. From Pennsylvania Crusher Co. E.P. 187,904, 15.2.22.

Pulverising apparatus. R. E. H. Pomeroy. E.P. 188,173, 13.10.21.

See U.S.P. 1,427,322 of 1922; J., 1922, 796 A.

Drying pulverulent material. E.P. 187,320. *See* VII.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Carbon and coal; Oxidation of different varieties of —— by chromic acid. D. Florentin. Bull. Soc. Chim., 1922, **31**, 1068—1072.

An attempt to replace the older methods of analysis by oxidation by means of a mixture of sulphuric and chromic acids in the case of determinations of carbon in fuel, leads to the conclusion that the method is not sufficiently trustworthy without some modification. Experiments were made on oxalic acid, tartaric acid, lampblack, graphite, coke, anthracite, hard coal, and bituminous coal; with the exception of the two first-named substances, the carbon dioxide obtained corresponded to a deficiency in the carbon content varying from 0·60% to 27·50%. In each case the carbon deficiency represented carbon which had been oxidised to carbon monoxide; this was converted into dioxide by being passed over copper oxide heated to redness and a value for carbon in accordance with the true carbon content thus obtained. The suggestion is made that the precaution of oxidising carbon monoxide should be taken in all sulpho-chromic oxidations, particularly in the case of estimations of carbon in iron and steel.—H. J. E.

Peat; Removal of water from —— below 100° C. Wo. Ostwald and A. Wolf. Kolloid-Zeits., 1922, **31**, 197—200.

Heating peat to 100° C. for several hours leads to the separation of water and changes in the degree of dispersion and other colloid-chemical properties. The changes are similar to those observed in the ten Bosch process which is carried out under pressure and at high temperatures (*cf.* J., 1922, 318 A, 319 A).—J. F. S.

Producer-gas equilibrium at high pressures. K. Jellinek and A. Diethelm. Z. anorg. Chem., 1922, **124**, 203—229.

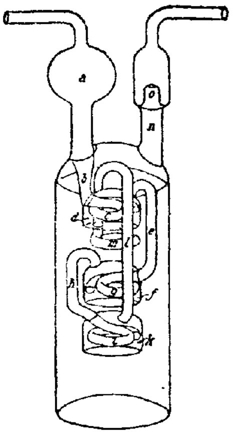
The electric oven employed was a modification of that used by Nernst (Z. Elektrochem., 1907, **13**, 52); it allowed measurements to be carried out at 1300° C. and at 150 atm. The reaction $C+CO_2 \rightleftarrows 2CO$ was investigated between 800° and 1000° C. at pressures up to 50 atm. Various forms of charcoal were employed, and the equilibrium, which was well defined, was practically the same in each case, and again the same in the case of graphite; the law of mass action was obeyed at all pressures. The integration constant of the reaction isochore of producer gas equilibrium was found to be 3·876; this agrees well with the value (3·80) calculated by means of Nernst's heat theorem. The authors show that the maximum work of this important reaction is equal to the heat effect if the reaction is carried out isothermally and reversibly and if the excess of oxygen has the same pressure as the carbon dioxide formed. —W. T.

Moisture content of producer gas; Estimation of ——. E. Maase. Feuerungstech., 1922, **11**, 27—28.

The apparatus used consists of a vessel provided with stopcocks above and below and fitted with a thermometer and manometer. This vessel is surrounded by a water jacket which can be heated by means of a steam coil. The temperature is raised above the dew point of the moist gas, and a sufficient quantity of the gas passed through the inner vessel to ensure all air being expelled. The stopcocks are then closed and the pressure and temperature read off. Cold water is then passed through the water jacket and the temperature and pressure again read; from the difference between these and the first values the moisture content of the gas can be calculated.—W. P.

Benzol in coal gas; Determination of ——. A. Thau. Chem. Age, 1922, **7**, 636—638.

Naphthalene and water vapour are removed from coal gas by passage at a rate of 50 l. per hour through a solution of picric acid and through previously heated calcium chloride contained in a series of U-tubes immersed in a mixture of ice and salt. Benzol is then absorbed in medicinal petroleum oil contained in a wash-bottle, cooled to −15° C., or −20° C., and determined by the gain in weight. The gas leaving the bottle is passed through a meter. If a commercial oil is used as an absorbent it should be heated to 120° C. in open dishes before use and then it should retain a constant weight while passing dry air through it. The wash-bottle (see fig.) contains a series of coiled tubes and bells and is filled with oil to the top of the bell, *d*, before starting a test. The gas bubbles through the oil from the open ends of the coils, *c*, *g*, *i*, and *m*, successively.—H. Hg.



Methane; Concentration of —— in mine-damp. E. Berl and O. Schmidt. Z. angew. Chem., 1922, **35**, 633.

The quantity of methane discharged daily into the air from a mine rich in firedamp may amount to as much as 250,000 cub. m. The concentration of methane can be increased from its initial value of 1—2% to over 10%, and a gas capable of being utilised for the production of heat, mechanical or electrical energy, obtained, by absorption of the gas mixture in active charcoal, followed by fractional expulsion of the adsorbed gas, *e.g.*, by heating first to 100° C., then to 175° C. and treating with steam.—H. C. R.

Ignition of gases. II. Ignition by a heated surface. Mixtures of methane and air. W. Mason and R. V. Wheeler. Trans. Chem. Soc., 1922, **121**, 2079—2091.

In order to determine the most readily ignited mixtures of methane and air, mixtures of known composition, varying from 2 to 14% of methane, were admitted rapidly to an evacuated cylindrical quartz vessel of 81 c.c. capacity, which was heated in an electrical tube furnace. The lowest temperature to which the walls of the vessel had to be heated in order that a given mixture should ignite when admitted to it was taken as the ignition temperature. The mixtures most readily ignited contained 5—6% of methane, the relative temperature of ignition being 695° C. The most explosive mixture, containing 9·5—10% of methane, is more difficult to ignite in this manner. Mixtures containing proportions of methane outside the limits of inflammability at atmospheric temperatures can propagate flame at much higher temperatures near their ignition temperatures. The value for the ignition temperature is not identical with the temperature existing in the mixture the moment flame appears; there must be a pre-flame period during which the rate of reaction is rapidly increasing. The "lag" or pre-flame period diminishes with rise of temperature and is of the shortest duration in mixtures containing the lowest percentage of methane. At temperatures above about 1200° C., the ignition of any of the mixtures would be nearly instantaneous. In order to ignite a given mixture the source of heat must be maintained in contact with the mixture during the pre-flame period, otherwise acceleration will be retarded. The "incendivity" of a heated surface depends on its temperature, its duration of contact with the mixture, and the catalysing power of the surface to induce flameless combustion.—J. B. F.

Naphthenic acids. I. Isolation of petroleum acids and pure naphthenic acids from waste lyes of neutral distillate refining. Y. Tanaka and S. Nagai. Kôgyô-Kwagaku Zasshi (J. Chem. Ind., Japan), 1922, 25, 1031—1044. (*Cf.* T. Yoshimura, Petroleum Times, March, 1921.)

A crude mixture of petroleum acids was obtained by acidifying the waste lyes produced in the refining of a petroleum distillate from Kurokawa, Akita Prefecture. (The authors have specially used the term petroleum acids for the crude mixed acid.) It was a thick, dark liquid, sp. gr. 0·9853 at 15°/4° C., acid value 68·8, having an offensive odour, and formed a stable emulsion with water, mainly owing to the presence of alkylsulphuric acids. It also contained naphthenic acids, hydrocarbons, esters of alkylsulphuric acids, phenols, etc. The neutral impurities were removed by converting the crude petroleum acids into potassium soap, repeatedly shaking with petroleum ether (b.p. below 55° C.), and decomposing the soap with dilute hydrochloric acid. To facilitate the extraction, it is necessary to add alcohol (15—40% of the total volume of the soap solution) to the soap solution. The alkylsulphuric acids were decomposed and the decomposition product removed, by adding a quantity of copper oxide almost equivalent to the combined sulphuric acid and then distilling under 8—9 mm. pressure. The distillate was again converted into potassium soap, the neutral substances were extracted with petroleum ether, and the soap solution was decomposed with dilute hydrochloric acid. The resulting crude naphthenic acid had sp. gr. 0·9936 at 15°/4° C., n_D^{15}=1·4875, and acid value 230·4. It did not form an emulsion with water. It was fractionally distilled under reduced pressure, about 84% distilling at 170°—220° C. at 8·9—9 mm. The lower-boiling distillates (110°—170° C.) contained phenolic substances. The crude naphthenic acids were converted into their methyl esters, and pure naphthenic acids were obtained by saponifying the esters. The product was a colourless viscid liquid, having a very slight peculiar but not offensive smell, and the following characters: sp. gr. 0·9918 at 15°/4° C., n_D^{15} 1·4824, acid value 254·3, iodine value 0, mean molecular weight 220·9. —K. K.

Alcohol; Manufacture of industrial —— and alcohol motor fuel in the Philippine Islands. H. I. Cole. Philippine J. Sci., 1922, 21, 17—48.

The nipa palm and molasses offer cheap and easily manipulated sources of alcohol for use as a motor fuel. Alcohol alone cannot be used successfully with the present type of petrol engine, but in admixture with benzene or ether it forms an advantageous and efficient substitute for petrol, only minor alterations of the carburettor and spark being required. In the Philippines, where benzol is not available, the alcohol-ether mixture would be the most economical to produce. A satisfactory mixture for motor purposes should contain 40—45% of ether, together with 0·5—1% of pyridine, which acts both as a denaturant and as a means of neutralising the traces of acid produced by combustion. A summary of previous papers on the utilisation of nipa sap as a source of alcohol is appended.—G. F. M.

Drainage error in Bingham viscosimeter. Herschel. *See* XXIII.

Patents.

Smokeless fuel and coke; Production of ——. S. R. Illingworth. E.P. 187,328, 18.7.21.

Coal containing 14—20% of volatile matter and in which most of the resinic matter decomposes at or above 400° C. without the evolution of a large proportion of volatile matter, is heated to 600° C. Coal containing 12—14% of volatile matter and with a coking index of not less than 4 may be heated similarly in layers 2—3 in. thick. The smokeless fuel thus formed may be heated to higher temperatures for the production of coke.—H. Hg.

Fuel. H. J. Franklin and J. Pettingall. E.P. 187,351, 30.7.21.

Ten parts of asphalt or pitch is dissolved in 800 pts. of heated fuel oil and incorporated with 25 pts. of shale and 45 pts. of coal or coke, previously pulverised and mixed in the presence of steam; 160 pts. of tar and 20 pts. of peat impregnated with fuel oil may also be added. The mixture is moulded into blocks.—H. Hg.

Artificial fuel and method of making same. C. J. Greenstreet. U.S.P. 1,432,178, 17.10.22. Appl., 23.7.19.

Finely-divided solid fuel is temporarily suspended in liquid fuel, the viscosity of which is then increased by oxygenation so as to keep the solid fuel in permanent suspension.—B. M. V.

Destructive distillation of coal and like carbonaceous materials. F. J. and F. West (Legal representatives of J. West), H. D. Madden, F. Boardman, and West's Gas Improvement Co., Ltd. E.P. 187,263, 10.2.22.

Steam and air are supplied simultaneously or alternately to the lower part of a vertical retort in which coal is being distilled, being introduced through the centre of the worm extractor shaft and the barrel of the worm. The air may be induced by the steam, or each may be admitted through a three-way cock controlled by the rod which actuates the extractor.—H. Hg.

Carbonisation of coal. J. Roberts. E.P. 187,336, 20.7.21.

Caking coal is mixed with non-caking coal containing 20—45% of volatile matter in such proportion that the non-caking coal utilises the excess of binding material in the caking coal during carbonisation, thus preventing expansion and securing a product with a bright and hard outer layer. The mixture is crushed to pass a 0·1-in. screen and is carbonised at 600°—760° C. The non-caking coal may be prepared from caking coal by heating it to 100°—350° C. in the presence of air. Coke breeze may be substituted for part of the non-caking coal. —H. Hg.

Carbonaceous char; Method of making finely-divided ——. H. Rodman, Assr. to Rodman Chemical Co. U.S.P. 1,433,039, 24.10.22. Appl., 9.9.18.

Coking coal is powdered and heated slowly to a coking temperature while exposed to the air, and with sufficient agitation to maintain the mass of coal in powdered form.—B. M. V.

Combustible gas and method and apparatus for generating and burning the same. S. Biddison. E.P. 162,646, 6.4.21. Conv., 29.4.20.

Oil and steam are passed into a tubular superheater, each element of which contains a longitudinal partition terminating short of its rear end. The steam boiler and the superheater are arranged above a pan in which oil is burnt to start the process and above burners in which part of the gas produced is subsequently burnt. The superheater is thus heated to 1000°—2500° F. (about 540°—1370° C.). When using crude oil this is mixed with the steam before entering the superheater. Water is supplied to the boiler from a float chamber through a non-return valve which is provided with a by-pass tube arranged below it, so that a constant water level is maintained within the boiler.—H. Hg.

Carburetted water-gas; Manufacture of ——. Fuller-Lehigh Co., Assees. of G. H. Kaemmerling and H. W. Benner. E.P. 171,079, 7.7.21. Conv., 2.11.20.

During the early part of the steam-blasting stage of water-gas manufacture, powdered bituminous coal is introduced into the upper part of the generator. Part of the water-gas is compressed into a vessel from which it is admitted intermittently into a coal container which communicates with the generator, so that the coal dust is carried forward in a series of puffs. During the introduction of coal the steam supply is restricted so as not to carry the coal out of the generator; steam is then supplied at the normal rate during the remainder of the blasting period, and the water-gas produced may or may not be mixed with the carburetted gas produced during the introduction of coal. The water-gas may be produced entirely from the coke derived from the coal or partly from other non-volatile fuel fed to the generator.—H. Hg.

Suction gas producer plants with special reference to vehicle driving. J. I. Thornycroft and Co., Ltd., and J. E. Thornycroft. E.P. 187,022, 12.7.21.

In order to allow gas to escape directly to the atmosphere and to maintain the suction at low load, an exhauster is fitted which does not influence the producer at full load but only acts at low load. —W. P.

Gasification of coal and other carbonaceous material; Methods and means for the ——. A. S. Foster. E.P. 187,076, 15.8.21.

The plant comprises a retort chamber above a producer. The retort is heated by external gas flues, and the bottom of the retort can be steamed. A steam superheater and distributor is arranged in conjunction with or adjacent to the producer grate, so that two parts of the grate may be steamed alternately, enabling one part to be steamed for the production of water-gas whilst the other is subjected to the air blast, thus allowing continuous working. —W. P.

Gas generators. E. Turner. E.P. 187,277, 16.6.21.

A stream of liquid or powdered solid fuel is directed downwards on to the apex of a cone. Air is admitted separately for the combustion of any non-volatile deposit upon the cone, whereby the cone is heated. Steam may be mixed with the air. The gases thus formed pass downwards through an annulus formed by the cone and the inner wall of an outer chamber, and then upwards through the chamber. There may be a water-seal at the bottom of the annulus for the reception of ash and the generation of steam. The cone may be heated internally by waste gases from a furnace or engine or by the combustion of oil or gas; in the latter case the products of combustion pass through perforations into the lower part of the annulus. The cone may be heated externally also by a burner provided around its base or by electrical means. The gases may be enriched with oil in the outer chamber. The admission of fuel, air, steam, and water to the producer may be controlled by the pressure in the gas delivery main.—H. Hg.

Gas producer for firing or heating purposes. J. H. Marlow. E.P. 187,282, 20.6.21.

Air and steam are admitted under the grate of a producer through a T-piece the branches of which are so shaped as to direct the air and steam towards the fuel bed. Secondary air is preheated by passage through conduits arranged in the brickwork of the producer.—H. Hg.

Alcohol-ether mixtures [*motor fuels*]; *Manufacture of* ——. H. Wade. From F. E. Lichtenthaeler. E.P. (a) 187,051 and (b) 187,052, 27.7.21.

(a) The difficulty of preparing alcohol-ether mixtures when the ether is separately prepared is considerable owing to the high volatility of the ether. The necessity for the provision of special condensing and refrigerating plant has been overcome by passing the vapours obtained in the manufacture of ether from alcohol and sulphuric acid through a scrubber containing alkali and thence through an absorbing tower within which a stream of alcohol is flowing in the opposite direction. A certain amount of the ether is condensed before the vapours enter the absorbing tower and this is added to the weak alcohol-ether mixture, obtained in the tower, to produce a mixture suitable for motor fuel. By this means the handling of the ether as such is avoided and the alcohol-ether mixture has no more fire risks than ordinary petrol (b) Alcohol-ether mixtures are prepared direct from raw material containing sugars or starches, alcoho never being stored as such in bulk. Fermente mash is distilled and the alcohol concentrated in continuous still up to approximately 95%. portion of the alcohol so obtained is led off to a ether apparatus and converted into ether. Th remainder of the alcohol from the continuous sti is taken to an absorbing tower to absorb the purified ether vapours.—T. A. S.

Fuel for internal-combustion engines. H. R. Giles From D. F. Field. E.P. 187,326, 18.7.21.

Alcohol-ether fuels, owing to the formation acetic acid and other causes, are unsatisfactory. Th difficulties are overcome by the addition of rosin o and a small proportion of caustic soda dissolved i alcohol. A mixture consisting of alcohol (66 ove proof) 36·75%, ether 62%, rosin oil 1%, saturate solution of caustic soda in alcohol 0·25%, is satisfactory when used in a carburettor normal adjusted to use petrol.—T. A. S.

Alcohol fuels. S. W. Blake. E.P. 187,335, 19.7.21.

In the process described in E.P. 178,498 (J., 1922, 454 a) for the preparation of a fuel of high volatility and calorific value by treating a mixture of commercial alcohol and acetone in a pressure vessel with calcium carbide, the acetylene formed being absorbed, other monohydric alcohols, *e.g.*, amyl, butyl, and propyl alcohols, may be used instead of ethyl alcohol and yield satisfactory fuels. It is advantageous to retain approximately 10% of water in the fuel and to remove all lime. The alcohol used should be of low strength, *e.g.*, 90—92%. The presence of water in the fuel keeps the engine cooler and prevents carbonisation and consequent knocking. When preparing the fuel from the heavier alcohols, the water should be added to the acetone and the acetone-water mixture then added to the alcohol. The proportion of acetone is from 5 to 40% and the proportion of calcium carbide used from ¼ to ½ lb. per gall. The removal of lime is effected by adding ammonia and then passing carbon dioxide through the solution.—T. A. S.

Petroleum and petroleum distillates; Treatment of ——. A. E. Dunstan and F. B. Thole. E.P. 186,955, 9.5.21.

Substances having a highly adsorptive surface are prepared by the dehydration of natural or artificial inorganic gels. Many natural hydrated silicates and hydroxides come within this category but only few possess the necessary surface energy for effective employment. Varieties of fullers' earth, such as floridin, and bauxite are particularly useful, and suitable artificial gels may be prepared from gelatinous colloidal metallic hydroxides, such as iron and aluminium hydroxides. When petroleum distillates are filtered through the dehydrated gels the sulphur compounds are removed by adsorption. The amount of material required for desulphurisation of benzine may be readily determined, 4 lb. of floridin or 9 lb. of bauxite per gallon having been found sufficient in certain cases.—T. A. S.

[Oil] still. E. W. Isom and J. E. Bell, Assrs. to Sinclair Refining Co. U.S.P. 1,432,067, 17.10.22. Appl., 12.5.21.

The still consists of a heating unit through which oil is pumped and a larger receptacle. The support for the pump is flexible to permit movement with expansion and contraction of the pipework.

—T. A. S.

Oil shales; Method for distilling ——. P. Danckwardt. U.S.P. 1,432,101, 17.10.22. Appl., 8.3.20.

Highly heated waste shale and raw shale are continuously fed into a still. The heat derived from the waste shale distils off the volatile matter from the raw shale.—T. A. S.

[Oil] vapours; Process of filtering ——. W. C. and F. E. Wells. U.S.P. 1,433,050, 24.10.22. Appl., 15.2.19.

Oil is heated in a still, permanent neutral gas being passed through it. The resulting vaporous mixture is passed upwards through a filtering material, such as fuller's earth, which removes colour and bituminous material. The filtering material is maintained at a lower temperature than the oil and after passing through it the vapours are condensed.—T. A. S.

Oils, pitch, and the like; Process of obtaining* —— *from shales, coal, wood, etc. W. C. and F. E. Wells. U.S.P. 1,433,051, 24.10.22. Appl., 30.8.19.

The shale or other material is continuously fed into an annular retort, both surfaces of which are heated. A neutral heated gas is passed into the bottom of the retort and carries away the vapours.—T. A. S.

Petroleum, shale oil, coal tar, and the like, commonly classed as hydrocarbons; Process of refining ——. W. C. and F. E. Wells. U.S.P. 1,433,052, 24.10.22. Appl., 27.10.19.

The oil is heated in a still the bottom of which is covered with an inert fusible material. Permanent neutral gas is passed through, and the resulting mixed vapours are passed upwards through fuller's earth, which is maintained at a lower temperature than the oil in the still. The vapours are then condensed. The apparatus can be made to work continuously and the inert gas can be used repeatedly.—T. A. S.

[Hydrocarbon] liquids, fluids and oils; Process for the conversion of —— *into lower-boiling products].* J. H. Adams, Assr. to The Texas Co. U.S.P. 1,433,519, 24.10.22. Appl., 5.12.17.

Lower-boiling hydrocarbons are obtained by passing oil through a succession of heating chambers. Pressure is maintained in each chamber, and the vapours formed are removed.—T. A. S.

III.—TAR AND TAR PRODUCTS.

Phenanthrene; Solubility of —— *in various organic solvents.* H. Henstock. Chem. Soc. Trans., 1922, 121, 2124—2128.

The solubility of phenanthrene in purified organic solvents was determined at temperatures between −10° C. and +30° C. by evaporating the solvent from a weighed amount of saturated solution and weighing the solid residue. The results are expressed in curves and tables from which the following typical figures for the solubility in grams of phenanthrene in 100 g. of solvent at 0° and 20° C. respectively are selected:—methyl alcohol 1·20, 3·60, light petroleum (b.p. 60°—85° C.) 2·40, 6·60, ethyl alcohol 2·75, 4·80, glacial acetic acid —,

5·80, carbon tetrachloride 7·60, 19·00, ether 17·44, 36·78, acetone 25·5, 51·94, chloroform 25·50, 46·60, benzene —, 51·70, and carbon bisulphide 37·32, 72·08. The curves for carbon tetrachloride, ether, and acetone show marked breaks at 0°, 10°, and 15° C. respectively, which point to some change in the molecular association of the solvent or solute, probably of the latter, at those temperatures. At −10° C. phenanthrene is insoluble in methyl alcohol.
—G. F. M.

Collidine; Condensation of —— with acetaldehyde. H. Kondô and T. Takahashi. Yakugakuzasshi (J. Pharm. Soc. Japan), 1922, No. 487, 775—780.

By heating a mixture of collidine (10 g.) and paraldehyde (3·63 g.) in a sealed tube at 210° C. for 14 hrs., *αγ*-dimethyl-*α*′-propenylpyridine (2 g.), colourless oil, b.p. 110°—111° C. at 12 mm., was obtained. It gave *αγ*-dimethylpyridine-*α*′-carboxylic acid when oxidised with 25% nitric acid. On reducing with sodium and hot absolute alcohol, the base was converted into *αγ*-dimethyl-*α*′-propylpiperidine, colourless liquid, b.p. 184° C., having a slight nicotine-like odour.—K. K.

Catalytic activity of copper [in preparation of aniline]. O. W. Brown and C. O. Henke. J. Phys. Chem., 1922, 26, 715—727.

In continuation of previous work (J., 1922, 322 A, 406 A) the authors have investigated the catalytic reduction of nitrobenzene to aniline by hydrogen in the presence of copper catalysts prepared by the reduction of the precipitated oxide. Sabatier's conclusion that a catalyst so prepared is more efficient than one prepared from an ignited nitrate was confirmed. By the use of the former catalyst, much lower rates of supply of hydrogen may be used without reduction in yield, and the reaction may be carried out at a much greater rate. The best temperature for carrying out the reduction was found to be about 260° C. A small amount of iron in a copper catalyst prepared from an ignited oxide prevents the rapid decrease in activity of the catalyst. Copper deposited on asbestos was found to be capable of effecting the reduction at a much greater rate per grm. of copper than copper alone, but with high rates of supply of nitrobenzene, it quickly lost its activity. Copper on asbestos is a better catalyst than an equal volume of copper on pumice.—J. S. G. T.

Chlorophenols; Solubility of ——. N. V. Sidgwick and S. L. Turner. Trans. Chem. Soc., 1922, 121, 2256—2263.

The influence of the position of the substituents on the properties of the isomeric chlorophenols is distinctly abnormal, the abnormality being more marked in those properties measured at high temperature (boiling points, critical solution temperature in water) than in those measured at low (solubility in benzene). The differences in the critical solution temperatures in water are considerable and of the usual kind, the value for the ortho compound (173·0° C.) being by far the highest, while those of the meta and para compounds (130·8° and 129·0° C. respectively) come close together. Unexpectedly small differences, though of the usual kind, are observed for the heat of solution in benzene. From the curves representing solubility in water and benzene, the relative lowering of vapour pressure of the solvent can be calculated. The freezing point and vapour pressure of water are more depressed by the meta-compound, whilst for benzene the ortho-compound has the greatest effect.

IV.—COLOURING MATTERS AND DYES.

Azobenzene and aniline; Catalytic preparation of ——. C. O. Henke and O. W. Brown. J. Phys. Chem., 1922, 26, 631—638. (*Cf.* J., 1922, 406 A.)

Thallium prepared by the reduction of thallic oxide at 260° C. is an excellent catalyst for the reduction of nitrobenzene to azobenzene; with a rate of flow of 4·1 g. of nitrobenzene per hr. and a 13% excess of hydrogen, a yield of 90·2% of azobenzene and 4·3% of aniline is obtained. The activity of the catalyst decreases very rapidly with use. Gold has a high catalytic activity for producing aniline which decreases with use. Using this metal as catalyst the yield of aniline at 355° C. is almost quantitative.—J. F. S.

Arylazoglyoxalines; Some ——. F. L. Pyman and L. B. Timmis. J. Soc. Dyers and Col., 1922, 38, 269—272.

The arylazoglyoxalines of the type

where R is an aryl group, formed by coupling glyoxaline with diazonium salts in alkaline solution, are produced in widely varying yield according to whether the diazonium compound contains an *ortho*-substituent or not. Thus the percentage of the theoretical yield of 2-benzeneazoglyoxaline is 74%, of 2-*p*-bromobenzeneazoglyoxaline 85%, of 2-*p*-tolueneazoglyoxaline 84%, of 2-*p*-ethoxybenzeneazoglyoxaline 64%, and of 2-*p*-sulphobenzeneazoglyoxaline 52%, as against 26% for 2-*o*-tolueneazoglyoxaline, and 10% for 2-*o*-methoxybenzeneazoglyoxaline. On reduction with stannous chloride the arylazoglyoxalines having *para* substituents in the benzene ring undergo fission with formation of 2-aminoglyoxaline, but here also very varying yields were obtained ranging from 15% only from 2-*p*-tolueneazoglyoxaline to 26% from the *p*-ethoxy-compound, 43% from the *p*-sulpho-compound, and 56% from the *p*-bromo-compound. The compounds not containing a *p*-substituent give 65—75% yields of diaminophenylglyoxalines on reduction with stannous chloride (benzidine transformation). These diamines cannot be tetrazotised, the glyoxaline amino group apparently not reacting normally. 2-Benzeneazoglyoxaline, 2-*p*-sulphobenzenazoglyoxaline, and 2-*p*-sulphobenzeneazoglyoxaline-4.5-dicarboxylic acid dye wool brownish-yellow shades, but the colour is not fast to sunlight or washing. After-chroming rendered the colour with the latter compound fairly fast. 2-*o*-Methoxybenzeneazoglyoxaline gives brighter yellow shades than the other azoglyoxalines.—G. F. M.

Colouring matter of the fruit of Gardenia florida, L. T. Munesada. Yakugakuzasshi (J. Pharm. Soc., Japan), 1922, No. 486, 666—671.

The colouring matter of the fruit of *Gardenia florida*, L., grown in China, was extracted with water according to Kayser's method (J., 1884, 628) and decomposed with dilute hydrochloric acid in a current of carbon dioxide. The product was an amorphous powder, identical with crocetin from saffron (Decker, Arch. Pharm., 1914, 252, 139). It gave a potassium salt, $C_{14}H_{13}O_4K$, orange-yellow crystals, which changed, without melting, to a dark red substance between 270° and 290° C. A sodium salt, short yellowish-red needles, and an ammonium salt, reddish-yellow needles, were also obtained.

Cyanine dyes. Braunholtz and Mills. *See* XXI.

PATENTS.

Thionaphthisatin; Manufacture of ——. O. Y. Imray. From Society of Chem. Ind. in Basle. E.P. 186,859, 1.12.21.

THIONAPHTHISATIN is obtained by the interaction oxalyl chloride and β-thionaphthol in presence or sence of a diluent or a condensing agent. It rms a red crystalline powder, m.p. 153° C., and is valuable dyestuff intermediate. *Example.* 0 pts. of β-thionaphthol is mixed with 635 pts. of alyl chloride, and after stirring for some hours the ordinary temperature the mixture is heated the boiling point. The excess of oxalyl chloride distilled off, and the β-thionaphthisatin ex-acted from the residue with aqueous sodium car-mate, and precipitated with hydrochloric acid. me of the oxalyl chloride may, if desired, be re-aced by carbon bisulphide, and aluminium loride or sulphuric acid may be added as ndensing agents.—G. F. M.

termediates for the production of colouring matters; Manufacture of new ——. [*Nitroso-oxyalkylarylamines, oxyalkylated thiosulphonic acids, etc.*] British Dyestuffs Corp., Ltd., A. G. Green, K. H. Saunders, and E. B. Adams. E.P. 186,878, 30.8.21.

HE oxyalkylamino compound previously described .P. 181,750; J., 1922, 625 A) may be used not ly for the preparation of the "sulphato" dye-uff intermediates, but also for the manufacture of itroso-derivatives by treating them with nitrous cid, and in the case of secondary amines trans-rming the nitrosamine with hydrochloric acid. hese nitroso-compounds are also valuable inter-ediates, as they can be condensed with hydroxy-mpounds to oxazines, or with another amino-mpound to give an intermediate indamine which an be converted into an azine in the usual way. urther, for the manufacture of thiazines the new itroso-derivatives of oxyalkylarylamines etc. an be reduced and treated with sodium thiosul-hate to yield oxyalkylated thiosulphonic acids.
—G. F. M.

Blue] *anthraquinone vat dyestuff; Manufacture of a* ——. E. Kopetschin. G.P. 357,767, 28.7.14. Addn. to 356,922 (J., 1922, 853 A).

-MERCAPTO-2-AMINOANTHRAQUINONE is treated with ondensing agents capable of reacting with the ercapto group, or it is heated to a high tempera-ure, or its salts are condensed with 1-chloro-2-minoanthraquinone, whereby hydrogen sulphide is volved and N-dihydro-1.2.2′.1′-anthraquinone-zine (Indanthrene) is produced.—A. J. H.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

ellulose; Studies on ——. *III. Viscosity determination of cellulose* [*solutions*]. M. Nakano. Kôgyô-Kwagaku Zasshi (J. Chem. Ind., Japan), 1922, 25, 899—910.

PECIAL precautions which must be taken in the reparation of cuprammonium solutions are given. he viscosity of cuprammonium solutions of cellu-ose decreases with time until it attains a constant alue. A dilute solution attains a constant value uicker than a concentrated one; the viscosity of a ery dilute solution is constant from the beginning. With solutions of the same concentration, the ower the viscosity the less is the difference between he final and the initial values. The viscosity in-reases much more quickly than the concentration. he relative viscosity increases with the temperature. No appreciable decrease of viscosity due to loss of ammonia can be observed. Oxygen and light have the greatest effect on the viscosity. The ammonium complex of copper has a strong oxidase-like action on cellulose. Depolymerisation of the molecular aggregate of cellulose is due to the light. Of various previous treatments to which the cellulose was subjected, the most important in its effect on the viscosity was thermal treatment.—K. K.

Cellulose; Reactions of —— *with sodium chloride and other neutral salt solutions.* I. H. Masters. Chem. Soc. Trans., 1922, 121, 2026—2034.

WHEN pure cellulose, in the form of cotton wool free from acidity or alkalinity, is extracted with sodium chloride solution, an acid extract is obtained, and an alkaline extract containing an equivalent amount of alkali when the cotton is subsequently extracted with water. The amount of acid extracted by a 20% sodium chloride solution was on the average the same as that extracted by a $N/10$ solution (3·9 mg. of HCl from 10 g. of cotton), the extract eventually becoming quite neutral, but the phenomenon cannot be attributed to the washing or salting out of acid originally present in the cellulose, as after washing with water until the washings were free from chloride and alkalinity, and again passing sodium chloride through the cellulose, an acid extract was once more obtained. Temperature had no effect on the amount of acid and alkali extracted, nor did the use of boiling water accelerate the removal of alkali from the cotton which had been previously extracted with sodium chloride solution. Other salt solutions behaved in a similar way, the least quantity of acid obtained being 1·2 mg. in the case of the very slightly dissociated cadmium iodide.—G. F. M.

Hydrocellulose. E. Heuser and W. von Neuenstein. Cellulosechem., 1922, 3, 89—96.

THE hydrocellulose prepared from viscose cellulose by the method of Knoevenagel and Busch (J., 1922, 458 A) behaves as a uniform substance. It is completely soluble in caustic alkali solution, and is precipitated again without loss. On repeated methylation it forms dimethylhydrocellulose in quantitative yield, which also behaves as a uniform substance, being completely soluble in cold water and in many organic solvents. On acetylation dimethylhydrocellulose yields a monoacetyl derivative which is also substantially homogeneous. Hence it is concluded that the hydrocellulose of Knoevenagel and Busch is the "true hydrocellulose" in a pure condition. In this sense it differs from ordinary crude hydrocellulose prepared from cotton by Girard's method, which behaves, both towards alkali and on methylation, as a mixture of true hydrocellulose and cellulose. According to recent theories (*cf.* J., 1922, 8 A, 170 A) fibrous cellulose consists of an aggregate of double anhydrocellobiose molecules arranged in crystal symmetry and held together by "crystal valencies." It is assumed that the crystal valencies may be resolved by any process which destroys the fibrous structure without affecting the dimeric anhydrocellobiose units from which the crystal fibre substance was built up. Thus viscose cellulose would consist entirely of such amorphous cellulose without crystal valencies and of relatively low molecular dimensions (4 C_6). As such it would be susceptible to hydrolytic attack as a uniform substance, and the authors suggest that the "true hydrocellulose" is produced from the double anhydrocellobiose molecule by simple opening up of an anhydride position in one of the cellobiose residues, with the formation of a free carbonyl group but without depolymerisation of the dimeric molecule. Further chemical hydrolysis would involve depolymerisation, but the true hydrocellulose is presumed to have the same molecular dimensions as the amorphous cellulose from which it is derived.—J. F. B.

PATENTS.

Cotton bales; Impregnated ——. H. Wade. From International Cotton Protecting Co. E.P. 187,394, 25.8.21.

COTTON bales are rendered permanently proof against fire and bacterial deterioration by impregnating them to a depth of ¾—5 ins. with an aqueous paste containing boric acid and a small quantity (0·25—1·50% of the total weight of the paste) of a non-colouring fixing agent such as a soluble salt of zinc, tin, aluminium, or other suitable metal. The behaviour of cotton in bleaching and dyeing is not affected by this treatment. A suitable paste contains, per 100 galls., 5⅓ lb. of boric acid (prepared by treating borax with sulphuric acid and afterwards washing the product so that it contains a trace but not more than 0·1% of mineral acid) and ½ lb. of a mixture of equal parts of zinc and stannous sulphates.—A. J. H.

Silk fibres; Process for treating [degumming] ——. S. A. Waksman. U.S.P. 1,432,312, 17.10.22. Appl., 3.2.21.

RAW silk is degummed by subjecting it to the action of strongly proteolytic bacteria.—A. J. H.

Cellulose-ether solvent and composition. R. L. Stinchfield, Assr. to Eastman Kodak Co. U.S.P. 1,432,364–5, 17.10.22. Appl., 19.3.21.

A VISCOUS composition for films is made by dissolving a cellulose alkyl ether in a mixture of 97—20 parts by weight of tetrachloroethane with 3—80 parts by weight of (A) a lower monohydroxy aliphatic alcohol, or (B) an ester of a lower monocarboxylic fatty acid and a lower monohydroxy aliphatic alcohol.—W. C.

Cellulose-ether solvent and composition. W. R. Webb, Assr. to Eastman Kodak Co. U.S.P. 1,432,373–4, 17.10.22. Appl., (A) 5.4.21, (B) 16.11.21.

A VISCOUS fluid composition suitable for films consists of (A) an alkyl ether of cellulose dissolved in a solvent containing 90—10 parts by weight of ethylene chlorobromide and 10—90 parts of a lower monohydroxy aliphatic alcohol; or (B) a water-insoluble ethylcellulose dissolved in a mixture of 10—90 parts of methyl acetate and 90—10 parts of methyl alcohol.—W. C.

Composite material formed with condensation products; Manufacture of ——. Metropolitan-Vickers Electrical Co., Ltd., Assees of H. C. P. Weber. E.P. 169,451, 22.9.21. Conv., 24.9.20.

CELLULOSIC material, such as paper, is parchmentised by treatment with caustic soda, sodium zincate, or other suitable substance, and is then impregnated successively or simultaneously, and before or after removal of the parchmentising agent, with a phenol and formaldehyde and subjected to heat and pressure, whereby a condensation product intimately incorporated with the fibres is obtained. Alternatively, the fibrous material is parchmentised and impregnated at the same time with a mixture containing the parchmentising substance, phenol, and formaldehyde. For example, paper is continuously passed through a parchmentising bath containing 20% caustic soda (10—15% of sodium chloride is added to prevent excessive shrinkage), then in succession through a bath containing phenol and a chamber containing formaldehyde vapour and between hot rollers under pressure. It is afterwards washed and dried.—A. J. H.

Rosin material for sizing. J. A. De Cew, Assr. to Process Engineers, Inc. U.S.P. 1,433,124, 24.10.22. Appl., 28.9.20.

A ROSIN having superior sizing properties is produced by dissolving rosin and a rubber product in a suitable solvent and afterwards removing the solvent by distillation.—A. J. H.

Paper; Process for recovery of material for manufacture of ——. S. Kumagae and T. Chiba. E.P. 187,805, 26.9.21.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Mordants. III. Chrome. W. D. Bancroft. J. Phys. Chem., 1922, **26**, 736—772.

THE author reviews critically a part of the literature, more especially the work of Liechti and Hummel (J., 1893, 241) concerned with the use of chromic oxide as a mordant in dyeing wool, cotton, and silk, and bases thereupon a number of conclusions as to the *modus operandi* of the process, the chief being that the mordanting is due to adsorption, there being no evidence of the formation of a definite compound. (*Cf.* J. Chem. Soc., Jan., 1923.)—J. S. G. T.

Mordanting of wool with potash alum. W. W. Paddon. J. Phys. Chem., 1922, **26**, 790—793.

EXPERIMENTS are described from which it is concluded that, contrary to the opinion of Knecht (Knecht, Rawson, and Lowenthal, "Manual of Dyeing," 1910, 237), the mordanting of wool with potash alum does not lead to the formation of definite chemical compounds on the fibre, but is strictly an adsorption phenomenon, in which both alumina and sulphuric acid are involved.
—J. S. G. T.

Hypochlorite solutions. Dienert and Wandenbulcke. *See* VII.

PATENTS.

Dyeing animal or mixed fibres; Process for ——. Akt.-Ges. f. Anilin-Fabrik. E.P. 171,981, 1.11.21. Conv., 26.11.20.

DYESTUFFS which are precipitated by acids and have therefore hitherto been considered unsuitable for dyeing animal fibres in acid baths, may be satisfactorily used for this purpose provided that sulphite-cellulose waste liquor or the active substances contained therein (sodium ligninsulphonate, cell pitch, sugars) are added to the dye liquor. This addition also allows the conjoint use of dyes belonging to different classes, *e.g.*, substantive and acid dyes, and moreover, the elasticity, gloss, and handle of the animal fibre are preserved during dyeing. For example, wool is dyed in a bath containing 3% of Alkali Blue 4B, 10% of sodium sulphate crystals, 5% of sulphite-cellulose waste liquor of 28° B. (sp. gr. 1·24), and 2% of concentrated sulphuric acid. A similar proportion of sulphite-cellulose waste liquor is also used in a metachrome process of dyeing.—A. J. H.

Yarns; Apparatus for the treatment of —— *with dyes or other liquids.* L. N. La Fayette. E.P. 182,758, 7.12.21. Conv., 2.7.21.

THE apparatus consists of a vat having a false bottom perforated with holes over which are mounted vertical telescopic perforated tubes. Bundles of yarn, wound on hollow compressible cores, are piled one above the other on these tubes and by means of a spring contained therein are subjected to suitable pressure. By means of a pump, dye or other liquid is forced from the vat, through the bundles of yarn, downwards through the perforated telescopic tubes and through the false bottom. Alternatively, the liquor is circulated in the opposite direction.—A. J. H.

Dyeing apparatus. J. D. Henon. U.S.P. 1,433,276, 24.10.22. Appl., 3.9.21.

A DYEING apparatus consists of a vat divided, by means of a partition, into two compartments in one of which is a means for circulating the dye liquor through the vat. A deflector or baffle, semi-oval in cross-section, is fixed to the inner faces of the walls of the vat and the partition for the purpose of deflecting the dye liquor out of the lines of flow of least resistance.—A. J. H.

Indigo fermentation vat; Manufacture of stable concentrated preparations suitable for the ——. Farbw. vorm. Meister, Lucius, und Brüning. G.P. (A) 356,411, 25.12.13, (B) 357,087, 14.1.14, and (C) 357,680, 15.2.14. Addns. to 354,946 (*cf.* E.P. 22,148 of 1914; J., 1915, 1245 A).

(A) IN preparations described in the chief patent, maltose or maltodextrins instead of other water-soluble carbohydrates, are mixed with albuminous substances; before concentration of the product, indigo or indigo-white or further quantities of water-soluble carbohydrates may be incorporated with it. (B) To the preparations described above and during or after their manufacture, invertase or yeast is added, since these substances improve the subsequent working of the vat and also invert sugars which are present. (C) In preparations as described above, invertase or materials containing invertase, such as yeast, sterilised yeast and the like, are incorporated with either or both of indigo or indigo-white and water-soluble carbohydrates or their related products. In this case the addition of albumin is not necessary.—A. J. H.

Textile materials; Apparatus for dyeing or bleaching ——. J. Gott and F. Wallis. E.P. 187,669, 12.7.21.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Hydrocyanic acid; Preparation of —— *in large quantities in the laboratory.* E. Fritzmann. J. Russ. Phys.-Chem. Soc., 1920, 52, 227—234.

THE amounts of sulphuric acid and water with which potassium ferrocyanide is usually heated for the preparation of hydrocyanic acid are greater than is necessary and equally good yields of the acid are obtained with the same rapidity with 10 pts. of the ferrocyanide, 5 of sulphuric acid, and 8 pts. of water. The apparatus used for preparing, purifying, and condensing the acid is described.
—T. H. P.

Nitrogen, carbon and sodium carbonate; Reversibility of reaction between ——. C. K. Ingold and D. Wilson. Trans. Chem. Soc., 1922, 121, 2278—2286.

THE behaviour of the system nitrogen, carbon, and sodium carbonate can, for a wide range of temperature be represented by the equation,

$$x^2/(1-x)\times(1-p)^2/p=K^1,$$

where x is the proportion of combined sodium present in the liquid phase as sodium cyanide (*i.e.*, the yield of sodium cyanide reckoned as a fraction of the theoretical), and *p* is the partial pressure of the nitrogen calculated as a fraction of the total pressure of nitrogen and carbon monoxide, assumed to be constant at 1 atm., and K^1 is a derived constant ($K^1=K.p_{Na_2CO_3}.p^4_C/p^2_{NaCN}$). The heat of reaction and the latent heats of vaporisation of sodium carbonate, carbon, and sodium cyanide can be considered constant, hence $\log_e K^1$ is equal to $\alpha+\beta/T$, and, by combining this with the equation given above,

$$\log_{10}(x^2/(1-x)\times(1-p)^2/p\times\pi^2)=\alpha+\beta/T$$

where $\alpha=23{\cdot}91$, $\beta=-3118°$, π=the total pressure of nitrogen and carbon monoxide. This formula represents the behaviour of the system to a degree of approximation of 1% in x or p, equivalent to about 2° C. in T. The form of the function is shown by a diagram, where x is plotted against p for the temperatures 850°, 900°, and 950° C. A table of values of 100 x is given for temperatures from 850° to 950° C.—P. V. M.

Sodium chloride; Melting and freezing point of ——. J. B. Ferguson. J. Phys. Chem., 1922, 26, 626—630.

THE melting point of sodium chloride is 803·4° C. and the freezing point 803·1° C.—J. F. S.

Hypochlorite solutions; Determination of available chlorine in ——. F. Dienert and F. Wandenbulcke. Ann. Falsif., 1922, 15, 338—339.

ONE c.c. of the hypochlorite solution is diluted with 1 l. of water, 2 g. of ammonium sulphate (to prevent formation of iodate) and a few crystals of potassium iodide are added, and the liberated iodine is titrated with arsenious acid solution, using starch as indicator. The results obtained agree with those yielded by Penot's and Gay-Lussac's methods. Poncius' method, in which the hypochlorite solution is titrated directly with alkaline potassium iodide solution, tends to yield high results owing to the fact that the iodate first formed reacts comparatively slowly with the alkaline iodide solution added subsequently.—W. P. S.

Magnesium perchlorate; Preparation and properties of —— *and its use as a drying agent.* H. H. Willard and G. F. Smith. J. Amer. Chem. Soc., 1922, 44, 2255—2259.

THE hexahydrate of magnesium perchlorate may be prepared by dissolving magnesia in perchloric acid, and evaporating the solution until fumes of perchloric acid are evolved and crystallisation commences at the surface. The solution is then cooled to ordinary temperature with the addition of sufficient water to keep the mass semi-fluid. The crystals are separated by centrifuging, redissolved in water, and crystallised. The hexahydrate melts at 145°—147° C., has sp. gr. 1·970 at 25° C., and is non-deliquescent. The trihydrate is prepared by keeping the hexahydrate over phosphoric oxide at 20°—25° C. for a month. The product has sp. gr. 2·044 at 25° C., and the same melting point as the hexahydrate. The anhydrous compound is obtained by heating either the trihydrate or the hexahydrate at 170° C., in a current of air for some time and then at 250° C. for a short time. Magnesium perchlorate decomposes at 400° C., without melting, forming a mixture of the oxide and chloride. When moist gas is passed over anhydrous magnesium perchlorate the moisture is removed as efficiently as by phosphorus pentoxide.
—J. F. S.

Hydrous oxides. IV. Hydrous stannic oxide. H. B. Weiser. J. Phys. Chem., 1922, 26, 654-686.

THE so-called stannic and metastannic acids are not acids but hydrated oxides of compositions which vary with the method of formation. There are no definite hydrates of stannic oxide and oxysalts, complex stannates, and metastannates are not definite compounds, but adsorption products, the composition of which is determined by the age of the oxide and the concentration of acid or alkali used in the preparation. Hydrated stannic oxide adsorbs colloidal gold, silver, and platinum, forming purple masses, the most common of which is purple of Cassius. These masses are colloidal in character and of varying composition. A mixture of the hydrated oxides of iron and tin in suitable proportions is soluble in dilute solutions of ammonia, the reason being, that hydrated stannic oxide is peptised by ammonia and the colloidal stannic oxide adsorbs ferric oxide. Stannic oxide does not precipitate in the usual way from a solution of tin in nitric acid which contains a suitable amount of iron. This is due to the fact that ferric nitrate peptises hydrated stannic oxide when the latter is either freshly precipitated or when it is aged. Stannic oxide jellies may be prepared by coagulating colloidal solutions of hydrated stannic oxide with small quantities of barium, strontium, calcium, and sodium chlorides or hydrochloric acid. —J. F. S.

Stannous oxide and stannous hydroxides; Preparation and reactions of ——. F. W. Bury and J. R. Partington. Trans. Chem. Soc., 1922, **121**, 1998—2004.

SIX specimens of stannous hydroxide (hydrated stannous oxide) were prepared from stannous chloride by the methods of previous investigators. Analysis showed the six samples to be essentially the same and support the formula, $3SnO,2H_2O$. No sample was entirely free from chlorine, although in most cases the amount was exceedingly small. Stannous hydroxide is stable up to 110° C.; it does not lose the whole of the water at 160° C., some of the water being probably constitutional; on standing under water it is slowly converted into stannous oxide. Several modifications of stannous oxide, differing in appearance, colour, and density have been described by Ditte (Ann. Chim. Phys., 1882, **27**, 145) and others, but the authors have found it impossible to confirm their statements in most cases.—J. B. F.

Nickel and cobalt hydroxides; Preparation of colloidal solutions of —— and some other compounds of these metals. O. F. Tower and M. C. Cooke. J. Phys. Chem., 1922, **26**, 728—735.

Two methods are described for preparing colloidal suspensions of nickel hydroxide, one by dialysing nickel tartrate in presence of an alkaline solution of potassium tartrate, and the other by precipitating and washing nickel hydroxide under special conditions. Only very weak suspensions of cobaltous hydroxide could be obtained by these methods. The characteristics of these colloidal suspensions are discussed. Colloidal solutions of nickel sulphide are readily formed in presence of an alkaline tartrate solution. (*Cf.* J. Chem. Soc., Jan., 1923.)—J. S. G. T.

Isomerism of metallic oxides. Part I. Lead monoxide. M. P. Applebey and R. D. Reid. Trans. Chem. Soc., 1922, **121**, 2129—2136.

IF pure lead hydroxide is dissolved in strong potassium hydroxide solution at a temperature near the boiling point, then on slowly cooling, the oxide is deposited in a well crystallised form. High alkali concentrations give rise to the red variety, moderate concentrations the yellow, and low concentrations yield a black or steel-grey variety of similar form to the yellow oxide. The red form crystallises in square plates, whereas the yellow gives needle-like rhombic crystals. The densities of the red and yellow varieties are 9·27 and 8·7 respectively. The solubilities of the two forms in *N*/1 sodium hydroxide were determined both gravimetrically and electrometrically; at 20° C., the solubility of the yellow form is about 1·8 times that of the red form. Evidence from solubility and from examination of crystalline structure shows that the yellow and red forms are polymorphic modifications. It is shown that the standard alkali electrode Hg/HgO in *N*/1 NaOH is easily reproduced and constant over long periods.—J. B. F.

Thorium oxide; Reduction of —— by metallic tungsten. Research Staff of the General Electric Co., Ltd., London (C. J. Smithells). Trans. Chem. Soc., 1922, **121**, 2236—2238.

WHEN a filament containing thoria is heated in a gas-filled lamp to a temperature of about 2700° K. the thoria is reduced to metallic thorium by the tungsten. As the heating is continued the thoria is converted into a grey, metallic, crystalline mass. These grey crystals are very stable towards acids and alkalis. On grinding the material and removing the unchanged thoria, the residue was not homogeneous, but contained transparent crystals varying in colour from yellow to blue, in addition to the grey metallic crystals. This mixture was not attacked by hydrofluoric and nitric acids, and on analysis gave Th=57% and W=26%. There is considerable evidence that the grey material is a thorium-tungsten bronze possibly of the form $Th(WO_3)_n$ where n may have a value from about 3 to 10. The coloured crystals are probably thoria containing small amounts of tungsten oxides in solution.—J. B. F.

Silica; Determination of —— in filtered sea water. R. C. Wells. J. Amer. Chem. Soc., 1922, **44**, 2187—2193.

THE most effective method of determining small quantities of dissolved silica in water consists in adding an aluminium salt, if such is not already present, and precipitating by ammonia in such quantity that the solution will give a pink colour with rosolic acid. The silica in the aluminium hydroxide precipitate is then estimated in the usual way. Silica cannot be estimated by the loss on evaporation with hydrofluoric acid in the presence of calcium sulphate. In rock analysis a single evaporation with hydrochloric acid is sufficient, provided silica is also determined in the ammonia precipitate. (*Cf.* J.C.S., Dec.)—J. F. S.

Silicates of strontium and barium. P. Eskola. Amer. J. Sci., 1922, **4**, 331—375.

THE attempt was made to explore the systems $SrO-SiO_2$, $BaO-SiO_2$, and to synthesise strontium and barium compounds analogous to diopside and anorthite by quenching mixtures of the oxides from various temperatures and studying the crystallographic and physical properties of the separated phases. In the $SrO-SiO_2$ system, the compounds formed are SrO; $2SrO,SiO_2$ (m.p. above range of electric furnace); SrO,SiO_2 (m.p. 1578°); and SiO_2. The eutectics $2SrO,SiO_2-SrO,SiO_2$ and SrO,SiO_2-SiO_2 melt at 1545° and 1358° respectively. In the similar barium system the main points are BaO, $2BaO,SiO_2$, eutectic $2BaO,SiO_2-BaO,SiO_2$ at 1557°, BaO,SiO_2 (m.p. 1604°), eutectic $BaO,SiO_2-2BaO,3SiO_2$ at 1437°, $2BaO,3SiO_2$ (m.p. 1450°), eutectic $2BaO,3SiO_2-BaO,2SiO_2$ none, the two forming a complete series of solid solutions, $BaO,2SiO_2$ (m.p. 1420°), eutectic $BaO,2SiO_2$-tridymite at 1374°, SiO_2. The dibarium trisilicate and the barium disilicate had a melting point diagram of Bakhuis Roozeboom's type I. without maximum or minimum, were isomorphous and of orthorhombic symmetry, and their refractive indices showed a continuous but not linear variation with composition. Attempts in both series to produce different modifications, *e.g.*, of SrO,SiO_2, which was isomorphous with and optically very similar to α-CaO,SiO_2, failed although both heating at varying temperatures for different lengths of time and crystallising from the corresponding vanadate were tried. The strontium and calcium metasilicates formed a continuous series of solid solutions, with a minimum at 1474°±3, corresponding to 44% CaO,SiO_2, 56% SrO,SiO_2. The crystals were pseudo-hexagonal and really monoclinic. The refractive indices showed a continuous variation with composition. Barium metasilicate, on the other hand, did not mix at all with calcium metasilicate, but gave a compound $2CaO,BaO,3SiO_2$ having no true melting point and breaking up on heating to α-CaO,SiO_2 and liquid. This compound was optically unlike all the other metasilicates. Points on the curve were the invariant point $CaO,SiO_2-2CaO,BaO,3SiO_2-$melt at 52% BaO,SiO_2 (1320°±4), and eutectic

$$2CaO,BaO,3SiO_2-BaO,SiO_2$$

at 73% BaO,SiO_2 (1267°), the liquidus of BaO,SiO_2 having a steep course toward the high melting point of BaO,SiO_2. Neither the strontium nor barium metasilicates gave with magnesium metasilicates compounds analogous to diopside, $CaO,MgO,2SiO_2$. This was regarded as a special case of the more general rule that in compounds in which the calcium is replaceable by magnesium or ferrous iron, it cannot be replaced by strontium or barium, while the isomorphous series including the latter may have isomorphous and miscible analogues among the sodium, potassium, or lead compounds. Both strontium and barium metasilicates with aluminium silicate gave felspars with very high melting points (much above 1700° C.). The crystals obtained were from melts at 1400° with three times the amount of the corresponding vanadate. The artificial strontium felspar was exactly like the calcium compound, anorthite, in optical properties, but the crystals were too poor to admit of investigation. The barium compound in optical properties resembled the natural celsian, no evidence being found of the existence of a nephelite analogue described by Ginsberg (Ann. Inst. Polyt. Pierre le Grand à Pétrograde, 1915, 23).—A. C.

Copper sulphate; Technical preparation of ——. T. Matsuno. Kôgyô-Kwagaku Zasshi (J. Chem. Ind., Japan), 1922, **25**, 926—930.

Copper sulphate was prepared on a large scale from roasted cement copper containing: soluble copper (expressed as CuO) 59·06, insoluble copper (Cu_2O) 2·58, soluble iron (FeO) 11·05, insoluble iron (Fe_2O_3) 3·40, silicic acid 2·41, and oxygen etc. 21·50%. About 100 cub. ft. of warm water is poured into a dissolving tank (about 200 cub. ft. capacity), 8 lb. of sulphuric acid of 50° B. (sp. gr. 1·53) is added, and after agitation for 10 min., the calculated quantity of copper is introduced, the temperature of the bath being maintained at 60°—80° C. After 10 min., further quantities of the acid and copper are added, and the process is repeated until about 1500 kg. of copper has been added. The solution is then transferred to an evaporating bath by means of siphons and concentrated to 34·5° B. (sp. gr. 1·314), then transferred to a crystallising tank, in which many lead plates are suspended for supporting the crystals. The crystallisation is completed in about 1 week. The product is collected, crushed, washed with water and dried at about 50° C., the yield being about 1 ton. The extraction of copper is more than 92%, and the product contains only 0·05% Fe and no other impurities.—K. K.

Thiosulphate of bismuth and sodium; Double ——, *its preparation and use in estimations of potassium salts.* V. Cuisinier. Bull. Soc. Chim., 1922, **31**, 1064—1068.

Methods of preparation of this reagent as given by other authors are criticised and the following procedure recommended: Bismuth chloride solution is prepared by dissolving 10 g. of bismuth subnitrate in 10 c.c. of pure hydrochloric acid under the influence of heat. On cooling, the volume is made up to 100 c.c. with 95% alcohol and sufficient additional hydrochloric acid to maintain the clearness of the solution. To this is added an equal volume of sodium thiosulphate solution made by dissolving 20 g. of the crystalline salt in distilled water and making up to 100 c.c. After mixing, five times the volume of 95% alcohol is added and if the whole does not remain clear, any opacity is removed by the addition of hydrochloric acid, drop by drop, and shaking. After standing for 15 min. a crystalline precipitate of sodium bismuth thiosulphate is formed, which is washed with alcohol and dried in a vacuum over sulphuric acid. On exposure to air the crystals rapidly turn brown. In using this substance for estimations of potassium, the author finds that the results obtained are invariably too high and that the weight of the precipitate depends on the concentration of the reacting solutions. The iodine value of the precipitate is not proportional to the potassium in the solution under examination and the results appear to vary with the volume of alcohol used as precipitating agent.—H. J. E.

Calcium hydroxide; Colloidal ——. M. von Glasenapp. Kolloid-Zeits., 1922, **31**, 195—196.

Two varieties of colloidal calcium hydroxide have been obtained from a marly dolomite of the composition, CaO 22·75%, MgO, 15·50%, Al_2O_3 7·68%, Fe_2O_3 1·87%, SiO_2 15·27%, CO_2 34·83%, H_2O 1·81%. The dolomite was burnt at 720°—780° C. until the magnesium carbonate was entirely decomposed and the calcium carbonate half decomposed. After the burnt product had been kept for 12 hrs. in water the two colloidal varieties of calcium hydroxide were microscopically visible. The primary product separates first from solution as small drops which grow speedily and pass into the secondary product, which forms agglomerates of drops having the appearance of a network of cells. Both colloids are optically isotropic but strongly refracting; in reflected light the primary colloid is light blue and the secondary colloid bright orange in colour. The secondary colloid does not maintain the colloidal state very long but passes into crystalline calcium hydroxide.—J. F. S.

Fuller's earth; Adsorption and catalysis in ——. E. K. Rideal and W. Thomas. Trans. Chem. Soc., 1922, **121**, 2119—2123.

The specific surface, adsorption, and catalytic activities of three typical varieties of fuller's earth (Florida, Surrey, and Somerset) are widely different. Adsorption of Methylene Blue in aqueous solution is proportional to the specific surfaces of the three varieties. The catalytic decomposition of hydrogen peroxide is not dependent on the adsorptive power, but is probably determined by the iron content.—J. B. F.

Hydrogen peroxide; Catalysis of —— *by ferric salts.* J. Duclaux. Bull. Soc. Chim., 1922, **31**, 961—966.

The author has investigated the velocity of the reaction between hydrogen peroxide and ferric chloride in presence of hydrochloric acid at 25° C., measuring the undecomposed peroxide with permanganate. His experimental results confirm those of Bohnson (J. Phys. Chem., 1921, **15**, 18) and von Bertalan (J., 1920, 656 A). In addition, he finds that the hydrogen ion concentration must be sufficient to eliminate hydrolysis of the ferric salt, otherwise inconsistent results are obtained. The theoretical side of the reaction is discussed (*cf.* J.C.S., Jan., 1923) and the general conclusion drawn that the action takes place between ferric ions and the HO_2 ions derived from the peroxide which behaves as a weak acid.—H. J. E.

Diffusion of hydrogen and helium through glasses. Williams and Ferguson. *See* VIII.

PATENTS.

Sulphuric acid; Process for the production of ——. T. Schmiedel and H. Klencke. E.P. 187,016, 12.7.21. Addn. to 149,648 (J., 1921, 693 A).

THE process described in the previous patent is modified by supplying the plant with nitrosylsulphuric acid of above 58° B. (sp. gr. 1·67), which may be maintained at an elevated temperature (about 50°—90° C.) if desired. The middle part of the plant may be sprayed with a solution of nitrosylsulphuric acid of lower strength than that used in the fore and rear parts of the plant, but above 54° B. (sp. gr. 1·598). Preferably the first units of the plant are supplied with nitrosylsulphuric acid of above 54° B., and in the following unit the nitrosylsulphuric acid is diluted with water to such extent (to below 50° B., *i.e.* sp. gr. 1·53) that its solvent power for nitrogen oxides is diminished, whereby large volumes of nitrous gases are suddenly evolved into the gas mixture and rapidly oxidise the remaining sulphur dioxide. The gas mixture is finally led through a chamber supplied with acid of above 54° B. for the absorption of the nitrogen compounds.—H. R. D.

Nitric acid; Process for recovering nitrous vapours in the form of aqueous ——. P. A. Guye, Assr. to L'Azote Français, Soc. Anon. U.S.P. 1,433,004, 24.10.22. Appl., 6.10.20.

FIBROUS material resistant to nitric acid is impregnated with water, and brought into contact with nitrous vapours diluted with an excess of nitrogen and oxygen.—H. R. D.

Magnesia; Manufacture of —— *from dolomite.* C. Clerc and A. Nihoul. E.P. 173,502, 20.12.21. Conv., 24.12.20.

DOLOMITE is calcined at such a high temperature (1000°—1200° C.) that the resulting magnesia can be hydrated only with difficulty whilst the lime is easily hydrated. The product is slaked with a quantity of water equal to about 20% of the lime present, sifted, and added gradually to, and mixed with, a solution containing magnesium chloride in excess, whereby the lime is converted into calcium chloride, and partially hydrated magnesia is obtained in a granular form which can be rapidly filtered and washed. The solution of magnesium chloride is made from the waste liquor of the ammonia-soda process by conversion of the calcium chloride in the liquor into magnesium chloride by reaction with the mixture of lime and magnesia in the presence of carbon dioxide.—H. R. D.

Sulphate of ammonia; Manufacture of [neutral] ——. W. C. Holmes and Co., Ltd., W. G. Adam, and C. Cooper. E.P. 187,035, 16.7.21.

AN improvement of the process described in E.P. 108,098 (J., 1917, 1007) consisting in mechanically conveying the crude damp and acid salt through a chamber through which is passed in the reverse direction a current of ammonia gas and heated air to effect the simultaneous neutralisation and drying of the salt. The apparatus comprises an inclined chamber of rectangular cross-section in which are located twin spiral conveyors partially overlapping, which convey the salt from the lower to the upper end of the chamber. The air is heated by passing it through a jacket surrounding the chamber and is then passed together with ammonia gas through the chamber.—H. R. D.

Ammonium sulphate; Continuous drying of pulverulent or granular materials, applicable to the manufacture of neutral ——. J. Marr, and The Coke Oven Construction Co., Ltd. E.P. 187,320, 16.7.21 and 26.4.22.

THE material is led continuously by pneumatic action and mechanical means through a rotary dryer, and exposed therein to a current of hot gases. The material is introduced into the feed conduit and conveyed to and from the dryer solely by pneumatic action, but in the dryer it is conveyed solely by mechanical means, for example by means of shelves. In the treatment of ammonium sulphate, the temperature of the gases should be such that the salt is not heated above 80° C. and ammonia is introduced into the feed conduit to neutralise any free acid and liberate any pyridine present.—H. R. D.

Potassium chloride; Method of recovering —— *from brine.* J. L. Silsbee. U.S.P. 1,432,796, 24.10.22. Appl., 12.4.20. Renewed 22.3.22.

A MIXTURE of salts containing chlorides of potassium and magnesium, separated from brine, is washed at approximately ordinary temperature with a solution of potassium chloride, whereby magnesium chloride is dissolved and part of the dissolved potassium chloride is separated. The washed material is separated, and the potassium chloride dissolved to form a hot saturated solution, which on cooling will deposit potassium chloride without precipitation of sodium chloride. The hot solution is separated from undissolved solids, cooled, and the potassium chloride which separates is removed from the mother liquor. —H. R. D.

Saltpetre manufacture; Process for ——. T. C. Meadows, M. Hauber, jun., and H. W. Charlton. U.S.P. 1,433,290, 24.10.22. Appl., 28.8.20.

GREENSAND, lime, caustic alkali, and sodium nitrate are digested at elevated temperatures and under superatmospheric pressure.—H. R. D.

Hydrogen; Process and apparatus for purifying ——. Deutsche Glühfadenfabrik R. Kurtz und P. Schwarzkopf G.m.b.H., Assees. of P. Schwarzkopf. E.P. 166,541, 13.7.21. Conv., 13.7.20.

HYDROGEN freed as far as possible from carbon monoxide and dioxide, oxygen, sulphur, and arsenic and phosphorus compounds by suitable successive treatments, is conducted over finely divided molybdenum or other similar metal of high melting point heated to incandescence (*e.g.*, 800°—850° C. for molybdenum powder), whereby the remaining impurities are removed. The gas after passing through the furnace is led by means of pipes over caustic soda to free it from any carbon dioxide formed, and is then dried. When the molybdenum becomes exhausted of its efficiency, it may be revivified by oxidation, dissolving, precipitation, and reduction.—H. R. D.

Nitrogen-carbonic acid mixture; Process and aparatus for the manufacture of pure —— *from combustion gases.* G. Scheib and M. Koch. E.P. 172,958, 13.12.21. Conv., 14.12.20.

COMBUSTION gases are passed over a contact substance consisting of a metal and its oxide, *e.g.*, copper and copper protoxide. A relatively large quantity of contact material is used and is kept in active condition by reducing the oxide formed by oxidation of the metal by means of reducing gases generated by passing an auxiliary current of combustion gases, separated from the main

current, over charcoal, benzol, petroleum, or the like, and then mixing this auxiliary current with the main current of combustion gases prior to entering the contact chamber. The apparatus comprises a furnace for generating the combustion gases, two conduits for the main current and auxiliary current of combustion gases, respectively, and a common channel into which these two conduits open and which leads to the tower containing the contact material. The conduit for the auxiliary current of combustion gases contains a support for the charcoal or the like used to generate reducing gases, and is connected with the combustion chamber by means of an adjustable flap. The process may be controlled automatically by regulating the supply of air for combustion according to the percentage of carbon dioxide in the combustion gases or by adjusting the position of the flap mentioned above according to the percentage of oxygen in a sample of gas taken from the middle of the mass of contact material.
—H. R. D.

Graphite; Purification of ——. M. Langheinrich. E.P. 187,080, 20.8.21.

Natural graphite is mixed with coal and heated by an electric current to a temperature of 2200° C. or higher, whereby the impurities (silica, alumina, pyrites, etc.) are reduced and sublimed. The volatilised impurities may be collected separately at different temperatures. The purified graphite retains its original flaky structure.—H. R. D.

Delivering measured quantities of acids. E.P. 172,011. *See* I.

VIII.—GLASS; CERAMICS.

Silica glass and other glasses; Diffusion of hydrogen and helium through ——. G. A. Williams and J. B. Ferguson. J. Amer. Chem. Soc., 1922, 44, 2160—2167.

Silica glass is permeable to hydrogen at high temperatures and pressures. The permeability is proportional to the gas pressure and is an exponential function of the temperature. It becomes appreciable at 300° C. Silica glass is similarly permeable to helium and the permeability is easily measured at 182° C. At 500° C. the permeability for helium is 22 times that for hydrogen. Neither pyrex glass nor Jena combustion tubing are permeable for hydrogen, but apparently hydrogen reacts with pyrex glass causing blackening. At 610° C. pyrex glass is permeable for helium.
—J. F. S.

Clays; Studies on ——. *I. Their chemical composition.* O. Boudouard and J. Lefranc. Bull. Soc. Chim., 1922, 31, 976—982.

A general discussion of the composition of clays taken from various sources. Analyses are quoted; the proportion of alkalis varies considerably in different samples of kaolin, and one specimen of halloysite is notable for its high calcium content. A stoichiometrical representation of the analytical results is given as a basis for comparison with the theoretical values for kaolin.—H. J. E.

Terracotta body; Effect of some fluxes on the absorption and transverse strength of a ——. E. C. Hill. J. Amer. Ceram. Soc., 1922, 5, 832—834.

A table is given of average results of shrinkage, absorption, and transverse strength tests on terracotta bodies of 2 clay: 1 porous grog, to which were added various amounts of fluxing materials, viz., felspar, Albany slip, powdered glass, white lead, cryolite, whiting and fluorspar, magnesium carbonate, and furnace slags. Insoluble materials, with considerable alkali content, such as felspars, powdered glass, and cryolite, appear to be the best fluxes. Depending on local economic conditions, most of the above fluxes, if free from discolouring impurities, can advantageously be used in place of vitrified grog.—J. B. P.

Enamelling of cast iron; Effect of sources of pig-iron on ——. M. E. Manson. J. Amer. Ceram. Soc., 1922, 5, 806—810.

An analytical investigation of enamelled cast iron made from two different sources of pig-iron showed that although blistering occurred continuously in one pig-iron, the only difference in the two irons was in combined carbon content. The silicon content of the unsatisfactory iron was then artificially reduced from 2·8% to 2·3%, and a metal with about 0·3% of combined carbon resulted, on which fairly successful enamelling was done. Whenever blistering occurred the combined carbon was found to have dropped to below 0·15%. However, from photomicrographs of blistered specimens, the direct effect of combined carbon on enamelling is doubted. These specimens showed characteristic dark blotches, which proved to be entirely surface phenomena. Tests did not show that enamelling lowered the initial combined carbon content, nor was evidence discovered that the blotches of the micrographs were developed during enamelling.
—J. B. P.

Heat-resisting alloys for enamel burning racks; Relative merits of ——. E. P. Poste. J. Amer. Ceram. Soc., 1922, 5, 811—816.

The results of oxidation and warpage tests, carried out at 1700°—1800° F. (about 910°—970° C.), on samples of the same size of basic open-hearth steel, cast steel, cast iron, calorised steel, "thermalloy," "misco," "nichrome," "rezistal," nickel, monel-metal, "calite," and "hardite," are given in comparative tables and graphs. Steels and cast iron are worst as regards warpage, while towards heat (*i.e.*, oxidation) "thermalloy" and "misco" showed fair, and the steels and cast irons poor, resistance.—J. B. P.

Silicates of barium and strontium. Eskola. *See* VII.

Patents.

Glass furnaces and the like; Recuperator for ——. W. McLaughlin, Assr. to C. E. Norton. U.S.P. 1,432,706, 17.10.22. Appl., 20.4.20.

The melting tank is provided with gas outlet flues along its walls, terminating in horizontal flues which converge into a chimney. Air inlet passages extending through the horizontal flues are spaced from the flue walls and are provided with burners near their inner ends. The inlet passages and the outlet flues are disposed in the same horizontal plane.—H. H.

Spinning nozzles from ceramic materials; Manufacture of ——. A. Kämpf, Assee. of G. Neumann. E.P. 166,533, 12.7.21. Conv., 12.7.20.

Fine metal wires of the thickness of the nozzle-openings are set parallel, in a mud of suitable ceramic material produced by the electro-osmotic process, in a cylindrical mould. The ceramic core is then dried, burnt (the process of hardening being regulated), and cut into discs of the desired thickness, the wires being removed by usual chemical methods.—J. B. P.

Waterproofing tile and the like. J. T. Pokorny, Assr. to A. T. Eddingston. U.S.P. 1,432,120, 17.10.22. Appl., 18.9.20.

Tiles are burnt in a high-domed furnace, into which coal-tar is then poured through hoppers which can be closed. Moisture is thus excluded, and the vaporised tar products are deposited on and absorbed by the tile.—J. B. P.

Molten glass; Method of and means for producing charges of ——. C. R. Lott. E.P. 187,661, 23.6.21.

Glass blowing; Method of and means for ——. V. Lorentz. E.P. 187,839, 21.10.21.

Glass making machines [*for producing pressed cups, etc.*]. E. A. Hailwood. E.P. 188,102, 20.8.21.

IX.—BUILDING MATERIALS.

Dolomite; Caustic calcination of —— *and its use in Sorel cements.* G. A. Bole and J. B. Shaw. J. Amer. Ceram. Soc., 1922, 5, 817—822.

In order to prevent the decomposition of calcium carbonate to the free lime so detrimental to an oxychloride cement, dolomites were calcined in special retorts having wrought iron or fireclay bodies, with a gas-tight chamber so constructed that the pressure of carbon dioxide inside the furnace could be kept constantly at 1 atm. With this furnace the material could be satisfactorily calcined at 700°—800° C., despite the fact (*cf.* Johnston, J., 1910, 1054) that calcium carbonate dissociates, under ordinary pressure, below 650° C. Data from tests showed that better cement is given and that calcination is generally quicker if burning can be done at 725°—750° C. Tests on floors and stuccos made from this calcined material showed satisfactory strength and good weathering resistance. There appeared to be no overburning, and only ores containing more than 4% of silica gave inferior cement.—J. B. P.

Patent.

Heat insulator. H. Mock. U.S.P. 1,433,088, 24.10.22. Appl., 23.5.21.

Insulating bricks are made with a core of powdered sulphur and an outer coating of asphalt or vulcanisable material.—J. B. P.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Aluminium; Treatment of —— *before nickel-plating.* E. Tassilly. Bull. Soc. Chim., 1922, 31, 973—976.

The methods recommended for preparing the surface of aluminium for nickel-plating (Mazuir, J., 1921, 13 A; Canac and Tassilly, J., 1914, 142; Tassilly, J., 1914, 697) include immersion in a bath of aqueous hydrochloric acid to which a small amount of iron or manganese has been added. The author has investigated the part played by the metal in the solution, also the relative advantages of iron and manganese, and finds that in the case of aluminium containing iron as impurity no such addition to the acid is necessary. In the case of aluminium which is practically pure, the effect of pure hydrochloric acid is so slight that some such addition is necessary to obtain the effect required in the acid bath. In default of an analysis of the metal to be plated, the addition is advisable in order to obtain a suitable surface, though possibly unnecessary. As the action is, in its results, of a mechanical nature, there is no advantage obtained by substituting manganese for iron.—H. J. E.

Aluminium-arsenic; The system ——. Q. A. Mansuri. Trans. Chem. Soc., 1922, 121, 2272—2277.

Aluminium combines with arsenic at about 750° C., under low pressures, to form the compound, Al,As,. Yellow arsenic is first formed and then reacts with the aluminium. The compound is a brown amorphous powder and does not melt at temperatures up to 1600° C. It is stable at high temperatures but begins to decompose at lower temperatures, yellow arsenic being first formed. When exposed to moisture it is highly reactive, evolving arsine freely. On heating in air it is oxidised to alumina and arsenious oxide. The solid compound does not appear to dissolve in molten aluminium, but separates out almost completely at its freezing point. It forms a strong and hard envelope round the aluminium. Attempts were made to prepare alloys of higher arsenic content, but without success. The brown compound did not form a eutectic with arsenic nor was a compound containing a higher proportion of arsenic obtained; the excess of arsenic separated out again as free arsenic. —J. B. F.

Tungsten alloys; Analysis of high-percentage ——. K. Seel. Z. angew. Chem., 1922, 35, 643—644.

The serious loss of platinum involved in the customary fusions of tungsten alloys with sodium and potassium carbonates and nitrates in platinum crucibles may be avoided by fusing the finely divided alloy with sodium hydroxide and nitrate in silver crucibles. The fusion takes about 1 hr. and the crucibles are not seriously attacked. 0·5 g. of the finely divided alloy is fused with 6 g. of sodium hydroxide and 3 g. of sodium nitrate. The melt is dissolved in water and filtered, the iron oxide remaining on the filter being dissolved in hydrochloric acid containing a little potassium chlorate, filtered, and the two filtrates united. The iron is determined as Fe_2O_3 as usual. The aluminium and the greater part of the silica are removed from the filtrate with ammonia, filtered off, and the tungsten in the filtrate precipitated with mercurous nitrate after acidifying, boiling off the carbon dioxide, and concentrating to about 150 c.c. The tungstic acid obtained by ignition of the precipitate is strongly contaminated with alkali, which is removed by repeated extractions with 7% hydrochloric acid, and traces of silica are finally removed by treatment with hydrofluoric acid. In the case of alloys rich in iron, a residue containing iron and tungsten remains after the original fusion. This is fused with pyrosulphate and the tungsten precipitated with nitric acid, determined as tungstic acid, and added to the figure obtained above. The iron in the filtrate is determined in the usual way and added to the figure obtained above.—H. C. R.

Lead; Determination of —— *in lead amalgam.* M. G. Mellon. J. Amer. Chem. Soc., 1922, 44, 2167—2174.

Quantities of lead amounting to 0·4 g. in 30—50 g. of mercury may be rapidly determined with an accuracy of 0·05% as follows: the sample of amalgam is covered with water containing one drop of 10% acetic acid, treated with 10 c.c. of 2*N* copper nitrate, and stirred continuously for 30 mins. The solution is filtered from metallic copper, which has not dissolved in the mercury, acidified with one drop of 10% acetic acid, and the lead precipitated as chromate by the usual method.—J. F. S.

Metals; Properties of cold-worked ——. Z. Jeffries and R. S. Archer. Chem. and Met. Eng., 1922, 27, 882—889.

While the general effects of cold working are an increase in hardness and loss of plasticity, other specific properties are affected in somewhat different ways, the yield point being affected probably more than any other property belonging to the hardness group. The effects of cold working are directional in the sense that the mechanical properties are influenced to a greater extent in the direction of working. Important changes may take place on the surfaces of slip during and after deformation. Immediately after slip commences, the slip plane strength, *i.e.*, the resistance to motion along the slip, is less than the strength of the crystals along parallel planes, but as the slip continues a reversal of these conditions occurs, otherwise fracture would occur quickly. Retardation of the original slip takes place partly by the interference of adjacent grains and partly by the resistance on the slip plane itself, leaving in a worked metal slip planes in all stages of deformation. Slip causes rupture of the atomic bonds on the slip plane, and after motion has ceased a partial re-establishment of cohesion obtains by fragments of the ruptured crystals joining into larger crystalline units which is attended with varying degrees of disorganisation owing to differing orientation. This disorganised metal simulates amorphous metal in its mechanical properties. Atomic rearrangement on slip planes takes place at much lower temperatures than are usually associated with recrystallisation as is exemplified by the spontaneous ageing of iron at atmospheric temperature. The excess of slip plane strength over crystal strength at low temperatures is the fundamental cause of the general increase in elongation with decrease in temperature. Since strain-hardness is to be attributed chiefly to the slip interference created by the relative displacement of crystal fragments, this hardening will be greater, in general, the larger the number of planes on which slip takes place, and accordingly deformation produces hardness more rapidly as the temperature is lowered, as the initial grain size is smaller, and finally when spontaneous union of the crystal fragments takes place during deformation as in the blue heat range in iron. (*Cf.* J., 1922, 941 a.)—C. A. K.

Patents.

Unstainable steel and iron or alloys thereof; Manufacture of ——. L. Aitchison. E.P. 187,310, 14.7.21.

Articles are formed (*e.g.*, by casting) from metal having the composition of unstainable metal, but containing carbon in excess of the quantity desirable in the finished product. The article is then decarbonised superficially by heating in a current of hydrogen or in contact with a suitable decarbonising agent. Cooling may take place in contact with the reducing agent to prevent partial re-carbonisation from the interior of the metal.—C. A. K.

Iron; Art of making electrolytic ——. F. A. Eustis, C. R. Hayward, H. M. Schleicher, and D. Belcher, Assrs. to F. A. Eustis and C. P. Perin. U.S.P. 1,432,543—4, 17.10.22. Appl., (a) 7.7.21 and (b) 17.1.22.

(a) A solution of a ferric salt is reduced by means of hydrogen sulphide, and the reduced solution is used for leaching sulphide ore, whereby the iron therein is dissolved and hydrogen sulphide liberated and utilised in reducing further quantities of ferric solution. The leach liquor is electrolysed for iron. (b) A solution of a ferrous salt for use in the electrodeposition of iron is made by dissolving iron oxide in a dilute acid solution containing a ferrous salt. —A. R. P.

Magnetic sand or finely divided iron ore; Treatment of ——. A. Naito. E.P. 187,810, 29.9.21.

The sand or ore is mixed with powdered coal and heated to produce a coke containing iron ore, which is heaped in the open air, and either sulphur dioxide or chlorine gas passed through, or sea water or a solution of caustic alkali poured upon it. The product is exposed to the atmosphere till large lumps or masses are obtained, which are charged with a suitable flux into a smelting furnace. —T. H. Bu.

Metals [iron]; Process and apparatus for pickling ——. E. H. Hinckley. U.S.P. 1,434,011, 31.10.22. Appl., 20.5.18.

Iron is immersed in an aqueous solution of sulphuric acid of such concentration and temperature that the efficiency of ionisation and capacity for absorbing ferrous sulphate are at a maximum. —T. H. Bu.

(a) *Ferro-uranium; Process of making* ——. (b) *Electric furnace.* F. F. Mueller and R. W. Harris, Assrs. to Standard Chemical Co. U.S.P. (a) 1,433,403 and (b) 1,433,404, 24.10.22. Appl., 20.10.20.

(a) Uranium oxide is reduced with a carbonaceous reducing material in an electric furnace provided with a lining composed principally of non-carbonaceous material. The temperature in the furnace is raised sufficiently to eliminate most of the carbon in the bath; iron is added to the bath, and ferro-uranium of low carbon and silicon content recovered therefrom. (b) The furnace chamber consists of a shell lined with uranium oxide. A bottom electrode is partly embedded in the lining and an upper electrode enters the furnace chamber.—J. S. G. T.

Rust; Process and composition for preventing ——. C. W. Porter. U.S.P. 1,433,226, 24.10.22. Appl., 8.4.20.

An aqueous solution of a volatile aliphatic amine is used as a rust inhibitor. Iron, for example, is treated with an aliphatic amine and a metallic hydroxide in aqueous solution.—C. A. K.

Tinplate scrap; Treatment of ——. Victoria Iron Rolling Co. Proprietary, Ltd. E.P. 170,861, 29.10.21. Conv., 30.10.20.

Detinning operations are carried out by forming a galvanic cell, using the tinned scrap as anode, a copper container as cathode, and a solution of sodium hydroxide as electrolyte. Copper troughs containing copper oxide, which acts as a depolariser, are attached to the copper vat, a permeable material being used to retain the copper oxide in the trough.—C. A. K.

Ore concentrator tables. E. C. R. Marks. From E. I. du Pont de Nemours and Co. E.P. 187,296, 12.7.21.

The surface of an ore concentration table is covered with a fabric, both sides of which are coated with a cellulose ester, such as pyroxylin. The ester before use is mixed with a white pigment so as to allow the lines of demarcation of the ore pulp to be easily seen, and, for the same purpose, the fabric extends over the sides of the table.—A. R. P.

Lead; Process for the production of metallic —— *from lead sulphate.* F. E. Elmore, and The Chemical and Metallurgical Corp., Ltd. E.P. 187,313, 14.7.21.

Lead sulphate produced in chemical processes is reduced to metallic lead by mixing it with 4—8% of carbon, preferably about 5%, and heating the mixture to 800°—1000° C. in a vessel to which access of oxidising gases is prevented.—A. R. P.

Metal oxides; Process for the reduction of —— *by means of aluminium in the furnace.* P. C. Rushen. From Akt.-Ges. B. Felder-Clement. E.P. 187,375, 13.8.21.

A metallic oxide is heated with aluminium in a crucible, it being immaterial whether the aluminium is in powder or in compact form; the oxide and aluminium are not mixed but are placed side by side or one above the other; or the oxide may be placed in a tube or the like made of aluminium. The intensity of the reducing action is such that there is a complete separation of metal from the aluminium oxide produced, the resultant metal being free from aluminium compounds. The process is particularly applicable to the reduction of the oxides of tungsten, molybdenum, chromium, titanium, and similar metals of high melting point. —C. A. K.

Alloy. F. Milliken. U.S.P. 1,432,607, 17.10.22. Appl., 8.10.19.

The alloy consists of 60—70% Cu, 9—12% Ni, 19—24% Zn, 1—2½% Fe, and a trace of manganese.—A. R. P.

Alloy [suitable for exposure to hot conditions]. A. H. Coplan. U.S.P. 1,433,180, 24.10.22. Appl., 7.3.21.

An iron alloy, which is to be exposed to combustion conditions in use, contains Cr 1%, Ni 2%, Mn not less than 0·60%, C not less than 0·1%, and small quantities of sulphur and phosphorus.—C. A. K.

Alloy metal. A. S. Hatfield. U.S.P. 1,434,246, 31.10.22. Appl., 9.2.21.

An alloy containing principally cobalt, together with tin and molybdenum, the percentage of the latter being more than twice that of the tin. —T. H. Bu.

Metallurgical apparatus. [Zinc furnace.] A. Donaldson. U.S.P. 1,432,842, 24.10.22. Appl., 19.3.21.

The retort of a zinc smelting furnace is connected to an external portable fume condenser, in which the condensing area can be varied.—C. A. K.

Lead and silver; Recovery of —— from ores and metallurgical products. H. Hey. U.S.P. 1,432,858–9, 24.10.22. Appl., (a) 24.2.20 and (b) 16.9.20.

(a) Ores and metallurgical products containing silver and lead as chloride are leached with a hot brine solution, containing a chloridising agent, such as ferric chloride, in such a manner that any sulphide present does not react with the silver in solution. (b) Sulphide ores containing lead and silver which have, by a preferential chloridising roast, been converted into chlorides, are leached with a cold acid brine to extract the silver. The residue is then treated with a solution which extracts practically the whole of the remaining lead. —A. R. P.

Metals; Treatment of ——. F. and F. Palmer. U.S.P. 1,433,408, 24.10.22. Appl., 29.4.21.

Metals are treated with an aqueous solution of sodium sulphate, sodium chloride, and potassium ferrocyanide.—C. A. K.

Extraction of metals from their compounds; Method of ——. P. Freedman and E. Greetham. U.S.P. 1,433,541, 31.10.22. Appl., 10.4.22.

See E.P. 180,384 of 1921; J., 1922, 596 a.

Pickling metals. O. Vogel. U.S.P. 1,433,579, 31.10.22. Appl., 13.8.19.

XI.—ELECTRO-CHEMISTRY.

Tungsten [electric] furnace for experiments on dissociation and ionisation. K. T. Compton. J. Opt. Soc. Amer., 1922, **6**, 910—912.

Tungsten sheet is bent into the form of a cylindrical tube and clamped by end pieces, each consisting of a steel ring fitting in a split rectangular steel block. The blocks are mounted on water-cooled brass tubes serving as leads for the heating current. Short glass tubes surround the leads for purposes of insulation. Loops of fine tungsten wire, drawn tightly round the cylindrical tube, prevent bulging of the furnace. The central electrode consists of a straight length of 20-mil tungsten wire welded to heavier molybdenum leads. A furnace 60 mm. overall length and about 5 mm. diam., was raised to a white heat by 100 amps. at 6 volts, and reached its melting point when a current of about 200 amps. was employed.—J. S. G. T.

Electrolysis with drops of mercury as the electrode. J. Heyrovsky. Chem. Listy, 1922, **16**, 256—264.

To study the electrolysis of aqueous solutions of alkali and alkaline-earth salts, the author employed drops of mercury as the electrode, whereby it was possible to determine the exact course of the electrolysis. Electrolysis is produced when a certain e.m.f. is applied, the value of which is characteristic of each salt and which is a function of the logarithm of the concentration. The rapid increase of the current is explained by a diffusion of very dilute amalgams towards the interior of the drop of mercury. The author calculated the following potentials at which the cations deposit from *N*/1 solutions on a mercury cathode:—Lithium, −2·023; sodium, −1·860; potassium, −1·883; rubidium, −1·796; cæsium, −1·837. The affinity of the metals for mercury is given by the difference between the characteristic potentials of polarised drops and the normal electrolytic potentials of the pure alkali metals, the following values being found:—Lithium, 1·281; sodium, 1·138; potassium 1·325; rubidium, 1·409; cæsium (1·50).—W. T.

Ozoniser; New form of ——. H. Nemecek. Chem. Listy, 1922, **16**, 276.

Two stout copper wires serve as electrodes in a horizontal glass cylinder, the arrangement being such that the distance between the electrodes can be varied. The energy can be obtained by means of a Ruhmkorff's coil or an electric machine. —W. T.

Oxides of lead; Physical chemistry of the ——. VI. Anodic behaviour of lead and lead dioxide. S. Glasstone. Trans. Chem. Soc., 1922, **121**, 2091—2098.

Oxygen is evolved at a lead or lead dioxide anode at almost identical potentials, *e.g.*, 1·18 and 1·17 volts respectively, for a current density of 0·03 amp. per sq. cm. The appearance of a dark film, which completely covers the anode in the case of lead, corresponds with a sudden increase of anodic potential and the evolution of oxygen. The evolution of oxygen at the lead and lead dioxide anode appears to be due to the formation of an intermediate unstable higher oxide, present in extremely small amount in solid solution in the dioxide. The initial high e.m.f. of a lead accumulator obtained soon after charging is probably due to the presence of this unstable higher oxide.—J. B. F.

Platinum resistance coils. Roebuck. *See* XXIII.

Patents.

(A) *Arc shield.* (B) *Moulded insulation and method of making same.* W. H. Kempton, Assr. to Westinghouse Electric and Mfg. Co. U.S.P. (A) 1,431,961 and (B) 1,431,962, 17.10.22. Appl., (A) 25.7.18, (B) 8.1.19.

(A) A mixture of Portland cement, asbestos, and water is placed in a mould, a space being left which is subsequently filled with a mixture of carborundum, Portland cement, and asbestos. The whole is compressed so as to form a solid piece, which is then removed and submitted to curing, heating, and drying processes. (B) Shaped pieces are formed by moulding a mixture containing a filler, such as asbestos, a binder, such as Portland cement, and an oxidising agent (siccative). The pieces are cured and impregnated with an oxidisable oil, *e.g.* linseed oil, which is then oxidised by the oxidising agent.—J. S. G. T.

Electric furnace [heater]. E. F. Collins, Assr. to General Electric Co. U.S.P. 1,432,442, 17.10.22. Appl., 1.3.21.

A ribbon-shaped resistance for use as an electric furnace heater is constituted of a number of edgewise convolutions, forming a self-supporting unit, and spaced so as to permit heat diffusion. —J. S. G. T.

Electric furnace. T. S. Curtis, Assr. to Universal Optical Corp. U.S.P. 1,433,448, 24.10.22. Appl., 7.8.19.

Horizontal electrodes enter the furnace chamber through opposite walls at the same height and are supported so that their distance apart may be varied and their relative positions determined by means of a graduated scale.—J. S. G. T.

Storage battery [plate]. W. H. Wood. U.S.P 1,432,937, 24.10.22. Appl., 22.1.20.

The lead oxide paste employed is incorporated, prior to setting, with finely granulated material consisting essentially of cellulose, which is afterwards gradually removed by means of sulphuric acid.—J. S. G. T.

Battery separator. W. H. Wood and H. E. Smith. U.S.P. 1,432,938, 24.10.22. Appl., 9.2.20.

A battery separator consists of an insoluble supporting medium interspersed with threads consisting of a mixture of mammalian hair, *e.g.*, wool, which is insoluble in sulphuric acid, and a porous vegetable fibre, *e.g.*, cotton, soluble in sulphuric acid.—J. S. G. T.

Separator for storage batteries. W. H. Wood. U.S.P. 1,432,939, 24.10.22. Appl., 17.4.20.

A storage battery separator is made of rubber composition traversed by strands of mammalian hair from which the scaly exterior portions have been removed.—J. S. G. T.

Electric battery [electrodes; Material for use in the manufacture of ——]. F. M. Holmes, Assr. to W. L. Valentine and G. D. Rigsby. U.S.P. 1,433,136, 24.10.22. Appl., 19.6.22.

Bone meal is treated with sulphuric acid, and after removal of substantially all traces of uncombined sulphuric acid, the resulting product, consisting of calcium sulphate and phosphoric acid, is dried in a finely divided condition. In like manner the finely divided product of the reaction between lead carbonate and sulphuric acid, consisting of lead sulphate and hydrated lead oxide, is dried after removal of substantially all traces of uncombined acid. The two products are thoroughly mixed with silica flour and a finely divided absorbent earth filler, and acid added to the mass.—J. S. G. T.

XII.—FATS; OILS; WAXES.

Copra drying; Use of sulphur fumes in ——. A. H. Wells and G. A. Perkins. Philippine J. Sci., 1922, 21, 49—55.

The main cause of colour and rancidity of coconut oil is the action of moulds on the copra during drying. Where steam drying is impracticable, sulphuring the copra is very satisfactory for the prevention of mould during air drying; 1 kg. of sulphur per charge of 3000 nuts is usually sufficient, and this is burnt in a pan on the floor of the sulphuring chamber, which may be about 4 ft. wide, 8 ft. long, 7 ft. high, the nuts being placed on trays piled one above the other on a trolley to facilitate removal. A preliminary sunning for an hour or so after opening the nuts is desirable, as the "meat" can then be separated more readily from the shells. The sulphured copra can be dried in two to three weeks in a shed without sunshine, if necessary, or more rapidly by sun-drying either on a floor or in light trays which can be stacked and covered up in case of rain. The direct protection against mould afforded by sulphur dioxide lasts about a month, but the copra is not susceptible to mould if once thoroughly dried and stored in a dry place. —G. F. M.

Illipé fat; Unsaponifiable matter (a highly unsaturated hydrocarbon and alcohols) in commercial ——. S. Kobayashi. Kôgyô-Kwagaku Zasshi (J. Chem. Ind., Japan), 1922, 25, 1188—1196.

A highly unsaturated hydrocarbon and a few higher alcohols have been isolated from the unsaponifiable matter of commercial illipé fat imported from India. The fat had the following characters: sp. gr. 0·9021 at 40°/4° C., m.p. 39°—40° C., acid value 17·2, saponif. value 181·0, iodine value 54·8, unsaponifiable matter 8·55%. 100 g. was saponified and the unsaponifiable matter was extracted with ether. It was a light yellow solid with an aromatic odour and the following characters: m.p. 148°—154° C., iodine value 178·5, saponif. value after acetylation 83·7, ether-insoluble bromide about 71%, bromine content 67·30%. It gave a white precipitate of digitonide with an alcoholic solution of digitonin and the bromide became blackish brown at 150° C. and turned black at 165° C. without melting. The unsaponifiable matter was treated with hot 95% alcohol, and from the insoluble matter a highly unsaturated hydrocarbon was isolated by repeated recrystallisation from ether. This hydrocarbon, illipene, $C_{32}H_{56}$, has m.p. 64·5° C., iodine value 382·5, and gives 312·2% of ether-insoluble bromide (67·46% Br). It is optically inactive and boils above 315° C. at 2·5 mm. pressure. The higher alcohols in the unsaponifiable matter were freed from sterols by means of digitonin and when fractionated by repeated recrystallisation from acetone gave the following compounds: $C_{21}H_{38}O$, microscopical silky needles, m.p. 196°—197° C., iodine value 114·9 and saponif. value after acetylation 150·7; $C_{31}H_{56}O$, silver-white crystals, m.p. 186°—186·5° C., iodine value 100·2; $C_{27}H_{48}O$, silver-white grains, m.p. 159°—160° C., iodine value 82·3; $C_{21}H_{36}O$, light yellow needles, m.p. 125°—135° C., iodine value 100·2, saponif. value after acetylation 132·5. The solid fatty acid in the fat is mainly composed of stearic acid.—K. K.

Rape oil; Composition of the fatty acids of ——. Y. Toyama. Kôgyô-Kwagaku Zasshi (J. Chem. Ind., Japan), 1922, **25**, 1044—1053. (*Cf.* J. Tokyo Chem. Soc., 1895, **16**, 187.)

Rape oil obtained from the seeds of *Brassica campestris*, L. (*B. chinensis*, L.) grown in the Shiga Prefecture had the following characters: sp. gr. 0·9147 at 15°/4° C., n^{20}=1·4734, acid value 1·6, Reichert-Wollny value 0·17, saponif. value 172·8, acetyl value 1·49, iodine value (Wijs) 102·8, and unsaponifiable matter 0·98%. The oil was saponified and the fatty acids separated and examined. Neither the lead-salt ether method nor the lead-salt alcohol method was suitable for separation of the saturated and unsaturated acids. The main constituent of the fatty acids of the oil was erucic acid, its quantity being about 65%. The quantity of saturated acids was less than 2%; palmitic acid was isolated and stearic, behenic, lignoceric, and arachidic acids were also probably present. After bromination of the liquid acids, freed from erucic acid, hexa- and tetra-bromostearic acids were isolated, and from the oxidation products by Hazura's method, sativic and isosativic acids were isolated, which proves the presence of linolenic and linolic acids in the oil. Methyl esters of the liquid acids, freed from erucic acid, when oxidised, yielded dihydroxystearic acid, indicating the presence of oleic acid. It was not found possible to separate the oleic acid by Reimer and Will's method (J., 1887, 732).—K. K.

Behenic and eracic acids; Derivatives of ——. Y. Toyama. Kôgyô-Kwagaku Zasshi (J. Chem. Ind., Japan), 1922, **25**, 1053—1055.

Erucic acid isolated from the fatty acids of rape oil crystallised from 90% alcohol in fine long needles, m.p. 33·5°—34° C. Behenic acid prepared by purifying hydrogenated erucic acid crystallised from 95% alcohol in thin scales with pearly lustre, m.p. 81°—82° C. A number of derivatives which may be of use for identifying the acids have been prepared. Methyl behenate, lustrous scales from 95% alcohol, has m.p. 54°—54·5° C., b.p. 224°—225° C. at 5 mm.; ethyl behenate, fine granules from 95% alcohol (irregular prismatic aggregates by microscopical examination), has m.p. 50°—50·5° C., b.p. 230°—231° C. at 5 mm.; behenic amide, fine needles from 95% alcohol, m.p. 111°—112° C.; behenic anilide, fine needles from 95% alcohol, m.p. 101°—102° C. Methyl erucate is a nearly colourless liquid, sp. gr. 0·8735 at 15° C., 0·8702 at 20° C., n^{15}=1·4577, n^{20}=1·4558, b.p. 221°—222° C. at 5 mm.; ethyl erucate, nearly colourless liquid, sp. gr. 0·8676 at 15° C., 0·8648 at 20° C., n^{15}=1·4562, n^{20}=1·4543, b.p. 229°—230° C. at 5 mm.; erucic amide, fine needles from 95% alcohol m.p. 82·5°—83° C.; erucic anilide, lustrous scales from 95% alcohol (short prismatic aggregates by microscopical examination), m.p. 65·5°—66° C.
—K. K.

Boring and cooling oils; Examination of water-soluble ——. K. Braun. Chem.-Zeit., 1922, **46**, 1016—1017.

The oil is weighed into a separating funnel, 100 c.c. of 60% alcohol added, the solution made alkaline and extracted with petroleum spirit (b.p. 30°—50° C.). The fatty oils and unsaponifiable matter are thus separated, and are weighed after drying at as low a temperature as possible. The weighed residue is saponified and again extracted with petroleum spirit. The residue gives the unsaponifiable matter and the difference the fatty oils. The alcohol is removed from the alcoholic soap solution after extraction with petroleum spirit and the residue dissolved in water, treated with excess of hydrochloric acid, and extracted with ether. The ethereal solution is washed with water saturated with ether until the washings are neutral, dried over anhydrous sodium sulphate, filtered, and the residue of fatty acids weighed after distilling off the ether. The free alkali cannot be determined by igniting the soap and titrating the ash with $N/10$ sulphuric acid and phenolphthalein owing to the presence of carbonates in the ash.—H. C. R.

Soap solutions; Constitution of ——. *Hexadecane sulphonic (cetylsulphonic acid and other sulphonates.* M. H. Norris. Trans. Chem. Soc., 1922, **121**, 2161—2168.

Hexadecanesulphonic acid is prepared by oxidation of hexadecylmercaptan with potassium permanganate. Manganese dioxide and a trace of oily dihexadecylsulphone are removed by filtration, and the lead salt of the acid is precipitated by lead acetate in hot slightly alkaline solution, washed with hot water and hot alcohol, and the acid liberated by treating a suspension of the lead salt in hot alcohol with hydrogen sulphide. Filtration and evaporation of the alcohol leaves a semi-solid mass, white at first, but turning brown. The acid is a hydrogen soap showing the typical behaviour of a colloidal electrolyte in conductivity, osmotic activity, and high temperature coefficient of solubility. It ranks among the highest soaps between sodium stearate and behenate. The length of the molecule is an important factor in producing a colloidal electrolyte. Sodium α-naphthalenesulphonate is less colloidal than the β-form, and ring compounds are far less colloidal than open-chain compounds with the same number of carbon atoms.—P. V. M.

Cotton seeds; Method and means for cleaning —. F. O. Partington. E.P. 186,943, 30.11.21.

The fibres adhering to cotton seeds, used for the manufacture of oil and oil meal or cake, are removed by the following method. The seeds are passed through a beater, where dirt is partly removed, and then through a revolving gauze cage in which the remaining dirt is removed. Afterwards, the seeds are conveyed through a carbonising chamber in which they are immersed in sulphuric acid of 80° Tw. (sp. gr. 1·40) or caustic soda, and are then centrifuged, dried, and cleaned in another revolving gauze cage.—A. J. H.

Catalyst; Method of restoring the activity of a —. G. A. Richter and W. B. Van Arsdel, Assrs. to Brown Co. U.S.P. 1,431,982, 17.10.22. Appl., 14.9.21.

The oil is extracted from a nickel catalyst with a solvent and the catalyst is then subjected to the action of an agent capable of dissolving the oxide film on it. The catalyst is washed to remove this agent and is sealed against the access of air.

Emulsifying materials. E.P. 187,298–9. *See* XIX.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Resins; Relation between ability to form — *and chemical constitution. III. New method for producing synthetic resins.* W. Herzog and J. Kreidl. Z. angew. Chem., 1922, **35**, 641—643.

The preparation of a number of synthetic resins is described in which organic substances containing the group .CO.CH:CH., are heated to 200°—250° C.

in a stream of carbon dioxide for periods of 2—12 hrs. Resins may be obtained in this way from benzylideneacetone, $C_6H_5CH:CH.CO.CH_3$, anisylideneacetone, $CH_3O.C_6H_4.CH:CH.CO.CH_3$, vanillalacetone, $(HO)(CH_3)C_6H_3.CH:CH.CO.CH_3$, cinnamylideneacetone, $C_6H_5.CH:CH.CH:CH.CO.CH_3$, cinnamylideneacetophenone, $C_6H_5.CH:CH.CH:CH.CO.C_6H_5$, and from the condensation product of terephthalaldehyde and acetone, $CH_3.CO.CH:CH.C_6H_4.CH:CH.CO.CH_3$. Resins can also be obtained from substances containing the "resinophorous" group, CO.CH:CH., as part of a cyclic group, in which form it occurs in the arylidene compounds of α-ketotetrahydronaphthalene (α-tetralone),

$$C_6H_4\left\langle\begin{array}{l}CO.C:CH.R\\ \qquad\ \ |\\ CH_2.CH_2\end{array}\right.$$

Attempts are made to ascribe all polymerisations of organic substances to resins to the presence of this "resinophorous" group. Modifications of Raschig's formulæ for phenol-formaldehyde condensation products (Z. angew. Chem., 1912, 25, 1946) are proposed by which the formation of these products also is brought into line with this theory.—H. C. R.

Patents.

Printers' ink [from sulphite-cellulose waste lyes]; Production of ——. K. J. Smidt and R. Jaeger. E.P. 187,537, 13.2.22.

The waste lyes from the manufacture of sulphite-cellulose are treated with nitric acid and a small quantity of metallic copper or zinc as catalyst; the reaction [redacted] phuric acid in suitable quantity may be added before the reaction is complete. The black product is of syrupy consistency, and is ready for use. —D. F. T.

Varnish; Method of making ——. J. H. Young, Assr. to H. H. Robertson Co. U.S.P. 1,432,511, 17.10.22. Appl., 22.4.20.

Resin is heated uniformly in a closed vessel by a hot liquid circulating outside, which simultaneously serves to heat the oil to be mixed with the resin. The hot oil is introduced into the melted resin and the heating is continued; later the temperature of the circulating liquid is reduced so as to cool the mixture prior to the introduction of a liquid thinner. Rapid cooling is then effected by further reduction of the temperature of the liquid in the jacket.—D. F. T.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Rubber compounded with sulphur and litharge; Comparative tests with ——. H. P. Stevens. Bull. Rubber Growers' Assoc., 1922, 4, 520—522.

Comparative tests on the rate of vulcanisation of mixtures of rubber with sulphur, with or without the presence of litharge, the rubber having been prepared or packed under different conditions, showed that litharge obliterates irregularities in the rate of vulcanisation due to the use of varying proportions of sodium silicofluoride, but increases the differences arising from the effect of moisture and mould. The latter influence is probably related to the known connexion between the activity of litharge and the acetone-soluble constituents of rubber.—D. F. T.

[Rubber;] Experiments on tearability [of ——*].* B. B. Evans. Indiarubber J., 1922, 64, 815—819.

Mixtures of rubber and excess of sulphur were made containing also zinc oxide, refined china clay, or light magnesium carbonate, one set of batches including these ingredients in equal proportions by weight and another set in equal volume proportions. "Accelerated" mixings of the latter type were also prepared. From each mixing strips were formed and united by vulcanisation. Measurement was then made of the load necessary to effect the separation of the joined surfaces. The mixings containing zinc oxide showed greatest resistance to tearing, and the clay mixings least. The direction of the "grain" in the test pieces had no appreciable influence on the results. Under-vulcanisation increased the ease of separation or tearing. The effect of the organic accelerator was to make separation more difficult.—D. F. T.

Air [of rubber factories etc.]; New method for estimating volatile substances in ——. E. Fritzmann and K. Macjulevitsch. J. Russ. Phys.-Chem. Soc., 1920, 52, 212—226.

The method elaborated by the authors for determining the proportion of light petroleum vapour contained in the air of rubber factories etc., consists essentially in freezing out the light petroleum in two weighed U-tubes, each cooled by immersion in liquid air. In order to prevent choking of the tubes by the frozen petroleum, the tubes are packed with magnesium turnings. Before being passed through these tubes, the air is freed from dust, moisture, and carbon dioxide by passage through tubes containing, in order, soda-lime, calcium chloride, phosphoric anhydride, and cotton wool. —T. H. P.

XV.—LEATHER; BONE; HORN; GLUE.

Tanning materials and extracts; Qualitative analysis of different —— and the detection of adulterants in mixtures. M. Jamet. J. Soc. Leather Trades' Chem., 1922, 6, 336—350.

A summary of all the different methods used in the qualitative analysis of tanning materials, including the following tests:—bromine, ammonium sulphide, lead acetate-acetic acid, formaldehyde-hydrochloric acid, and coloration of Mulhouse (mordanted) strips. 1% iron alum solution gives characteristic colours or precipitates with the individual tannins. Nitrous acid is used to show the presence of ellagitannic acid. If 1% copper sulphate solution is added to a solution of the tannin a precipitate usually forms. When excess of ammonia is added the precipitate dissolves if gambier, hemlock, or pine bark tannins are present. Tannins derived from gallotannic acid and others containing protocatechuic acid give copper tannates which do not dissolve readily in ammonia. 10 c.c. of a strong solution of stannous chloride in hydrochloric acid is added to 2 c.c. of a 0·4% solution of the tannin in a porcelain crucible and allowed to stand for 10 mins. A pink colour is obtained with barks of

conifers and mimosas. A splinter of pinewood, 5 cm. × 1 cm. is soaked in a 5% tannin solution, left to dry, then damped with hydrochloric acid. The splinter becomes a deep reddish-violet with tannins containing phloroglucinol, *e.g.*, cutch and gambier. The pinewood shaving becomes feebly coloured after a few hours with tannins containing traces of phloroglucinol. Sodium sulphite crystals moistened with a solution of valonia acquire a vivid red colour. If a test-tube is rinsed out with a tannin solution, the drops allowed to collect at the bottom, and 1 c.c. of strong sulphuric acid poured down the side, characteristic colorations are obtained with different tannins. Lime water also gives characteristic colorations with tannin solutions. If 5 c.c. of a 10% solution of normal lead acetate is added to 5 c.c. of tannin solution, the mixture filtered, and excess of 10% solution of caustic soda added to a portion of the filtrate, quebracho and ulmo give a faint yellow colour, lentiscus and sumach a bright yellow, and wood pulp a dull yellow, whilst other tanning materials give no coloration. The colour obtained on chromed wood is characteristic, sumach, galls, and chestnut giving a green colour, cutch, mimosa, mangrove, and quebracho a dull brown, and myrobalans a yellow. The author reviews the usual quantitative tests with ethyl acetate, ammonium molybdate, etc.
—D. W.

Leather analysis; Report of a committee [of the Soc. of Leather Trades Chemists] on ——. M. Chambard. J. Soc. Leather Trades' Chem., 1922, **6**, 358—362. (*Cf.* J., 1921, 859 A.)

Samples of the same leather were analysed in three different laboratories, and the results showed wide variation in the hide substance, grease content, and mineral matter. Greater care is necessary in specifying the portion of the leather from which samples should be taken.—D. W.

Fat-liquor [for leather]; Manufacture of ready-made stable —— from Indian oils. B. M. and S. R. Das. J. Soc. Leather Trades' Chem., 1922, **6**, 328—335.

The authors have demonstrated the possibility of sulphonating Indian castor oil and sardine oil and blending the products with mineral oils, neutral oils, and soap so as to form an emulsifiable mixture suitable for fat-liquoring chrome leathers.—D. W.

Gelatin gels; Thermal expansion of ——. A Taffel. Trans. Chem. Soc., 1922, **121**, 1971—1984.

The coefficient of expansion and the specific volumes of gelatin gels for a given temperature are a linear function of the concentration of the gel. With increase of temperature, the gels expand regularly. One gram of gelatin is always associated with the same contraction in a gel at any one temperature, irrespective of the amount of water contained in the gel; this contraction, per 1 g. of gelatin, is 0·073 c.c., and 0·065 c.c. at 15° and 32° respectively. The contraction of a gel is not due to the filling up of the pores in the solid gelatin by water; only a fraction of the water in a gel is contracted, the weight per gram of gelatin undergoing contraction being the same for gels up to 25% concentration by weight. The temperature of maximum density of water is lowered by gelatin by an amount proportional to the concentration (determined up to 13% concentration). This is due to the thermal contraction of the gelatin content of the gel and the increase in the contraction on imbibition of the gel with falling temperature.—J. B. F.

Patents.

Artificial leather; Process for the manufacture of ——. C. Claessen. E.P. 171,360, 8.7.21. Conv., 6.11.20. Addn. to 155,778 (J., 1922, 459 A).

Artificial leather, which is waterproof, is made by coating material, prepared as described in the chief patent, with a mixture containing cellulose esters, resin or similar substances dissolved in an excess of a volatile solvent. A suitable mixture consists of 10 pts. of nitrocellulose, 15 pts. of alcohol, 55 pts. of acetone, 15 pts. of benzol, and 5 pts. of castor oil (*cf.* also E.P. 174,317 and 174,588; J., 1922, 627 A).
—A. J. H.

Skin; Prepared —— for diaphragms, sound plates and amplifiers of gramophones. J. W. Barstow. E.P. 187,049, 26.7.21.

A substitute for mica, wood, and metal used in the manufacture of diaphragms etc., consists of raw animal skin which is steeped in water until supple, then immersed for about 10 hrs. in a solution composed of 1 pt. of alum and 2 pts. of water or 1 pt. of formalin and 3 pts. of water, and afterwards dried under tension, sand-papered, and coated with French polish, or amyl acetate, copal gum, or varnish.—A. J. H.

XVI.—SOILS; FERTILISERS.

Already indexed from origin

Humus soils; Mechanical analysis of ——. G. W. Robinson. J. Agric. Sci., 1922, **12**, 287—291.

To destroy the organic matter, 10 g. of soil is mixed with 30 c.c of hydrogen peroxide (20 vol.) and heated for 30 mins. on a steam bath. After repeating the process with 25 c.c. of hydrogen peroxide a peaty soil is usually sufficiently oxidised to caus complete dispersion of the particles. The mechanical analysis of the treated soil is carried out a usual, and microscopical examination of the fractions shows them to consist of mineral particle only. The larger aggregates, cemented together b organic matter, are entirely destroyed. The cla fraction has a very different appearance from tha obtained by the ordinary process without oxidation, and the coagulum is much smaller.
—A. G. P.

Already indexed-Original.

Mechanical analysis of soils and other dispersion New method for the ——. G. W. Robinson. Agric. Sci., 1922, **12**, 306—321.

A 2—2·5% suspension of soil is prepared in a t cylinder, and samples are withdrawn with a pipet at measured depths and after measured periods settling. It is then possible to represent graph ally the relationship between percentage of s and settling velocity. It is suggested that t most suitable method of representing the mecha cal composition of soils is by means of a graphic relationship between the summation percentage a the logarithm of the settling velocity. By suita choice of times and depths of sampling, the meth is readily adapted to any of the existing syste of fractionation. A weak solution of sodium c bonate (0·025%) is recommended for the suspensi medium. Cylinders should be not less than 1¼ in diameter. Errors of a few millimetres in t depth of sampling have little significance. Cl agreement with the older methods of analysis obtained, and the time required for the fractio tion is very considerably shortened. The coar fractions are removed by sieves, and the fine sa by one sedimentation of 75 secs., as by the us method.—A. G. P.

Soil moisture determination; Electrical method of ——. T. Deighton. J. Agric. Sci., 1922, **12**, 207—230.

The moisture content of soils is calculated from a determination of the resistance between two carbon electrodes pressed into the soil. The most satisfactory experimental conditions—*e.g.*, size and nature of electrode, distance between electrodes, etc.—are indicated. A consideration of soil moisture-resistance curves showed that the resistance varied with the square of the moisture content when the latter was above 10% ; but below this figure irregularities occurred due to alteration in the physical condition of the clay colloids.—A. G. P.

Soil colloids; Absorption of water by ——. W. O. Robinson. J. Phys. Chem., 1922, **26**, 647—653.

Clay, loam, and silt soils and subsoils absorb a relatively constant quantity of water, which lies between 0·240 g. and 0·348 g., with a mean value 0·298 g. per g. of colloid present.—J. F. S.

Soils; Action of neutral salts on ——. [*Determination of soil acidity.*] J. van der Spek. Vers. Landbouwk. Onderz. Rijkslandbouwproefstat., 1922, 162—202. Chem. Zentr., 1922, **93**, IV., 1009—1010.

A number of acid and alkaline soils were treated with various neutral salt solutions and the resulting hydrogen-ion concentrations determined electrometrically. Great differences in the effects of different salts were observed. That these effects are the outcome of adsorption phenomena is indicated by the different action of salts with the same anion or cation, and by the fact that the course of the reactions leading to the equilibrium position follows an adsorption isotherm. On the other hand, the equivalent interchange of cations and the course of reactions leading to the formation of substances of increased or decreased dissociation in solution favour the view that chemical reactions only are involved. Reactions occur between free ions in solution and adsorbed ions. The different conceptions of the nature of chemical reactions in soils become simplified if it be assumed that adsorption of ions occurs on the surface of colloidal particles, and that adsorbed ions are not washed out by water but can still take part in reactions, and are interchangeable with ions bearing similar charges. In nature, acid solutions, particularly carbonic acid and humic acid, withdraw adsorbed basic ions from the soil leaving the free H-ions. The estimation of soil acidity by spotting out soil extracts on litmus paper is therefore inaccurate, since all the free H-ions are not extractable by water. The colorimetric estimation of soil acidity is best carried out with a salt-solution soil extract, although results are unreliable unless standard conditions of concentration and quantity of soil and of extracting solution are observed. Correct results can only be obtained by potentiometric methods.—A. G. P.

Fungicidal sprays. Horton and Salmon. *See* XIXB.

Patents.

Fertilisers; Process for the manufacture of ——. A. d'Ercole. E.P. 179,934, 9.5.22. Conv., 14.5.21.

Tricalcium phosphate (45 pts.) is treated with sulphuric acid of 48° B. (84 pts.) in a superphosphate mixer. When the reaction is nearly complete 17 pts. of calcium cyanamide (19% N) is stirred into the mixture, which is immediately transferred to a vat and allowed to react for about 20 mins. before removal.—A. G. P.

Fertilising material; Manufacture of material suitable for use as ——. E. L. Pease. E.P. 187,251, 15.4.21.

Basic material containing substances utilisable as fertilisers, *e.g.* potash-bearing clays, shales, rock phosphates, etc., are treated with acid (sulphuric, hydrochloric, phosphoric) to produce a semi-dry absorbent mass. This is used as a scrubbing material to remove ammonia from coal gas, producer gas, etc. The product may be used directly as a fertiliser, or may be heated in a retort to remove the bulk of the ammonia and the residue again used for gas purification, or it may be leached with water to remove soluble fertiliser salts. In the latter case sufficient ammonia must be present to precipitate the iron and aluminium.—A. G. P.

Fertiliser and process of making same. E. H. Sams. E.P. 187,423, 14.9.21.

Household refuse, sewage sludge, etc., is dried, ground, and screened to remove metal, glass, etc., and sprayed with ammonia liquor from gas works in the proportion of 1 gall. to 10 lb. of refuse. The whole material is re-ground and can be used directly on the land.—A. G. P.

XVII.—SUGARS ; STARCHES ; GUMS.

Cane-sugar juice; New method of purifying ——. D. J. W. Kreulen. Chem. Weekblad, 1922, **19**, 458—461.

In the treatment with lime after the ordinary sulphitation process, there is always a large zone in which lime is in excess, causing formation of dextrose and tending to affect the subsequent crystallisation. An apparatus is described by means of which the milk of lime can be forced into the vat by compressed air, which serves to divide it and to distribute it rapidly and uniformly through the liquor, which is by this means also kept well agitated.—S. I. L.

Sugars; Iodometric determination of ——. F. Auerbach and E. Bodländer. Z. angew. Chem., 1922, **35**, 631—632.

In the iodometric determination of the excess of cupric salt remaining when a reducing sugar is boiled with Fehling's solution, the quantity of thiosulphate solution required to titrate the liberated iodine is not a direct measure of the amount of sugar present. For instance, each 0·1 c.c. of $N/1$ thiosulphate solution is equivalent to 0·34 mg. of invert sugar when 10 c.c. of the solution is required for the titration, and to 0·41 mg. when 23 c.c. is used. The use of potassium thiocyanate in place of a portion of the potassium iodide, as recommended by Bruhns (J., 1920, 829 A), is untrustworthy. —W. P. S.

Carbohydrates; Oxidation of —— *with nitric acid.* P. Haas and B. Russell-Wells. Biochem. J., 1922, **16**, 572—573.

Sucrose, lactose, dextrose, lævulose, and the carbohydrates of *Chondrus crispus* (carrageen), on oxidation with nitric acid yield a substance similar to glycuronic acid, which reduces cold Fehling's solution.—S. S. Z.

Xylose; Methylation of ——. A. Carruthers and E. L. Hirst. Chem. Soc. Trans., 1922, **121**, 2299—2308.

Two series of methylations were carried out with the object of obtaining the two stereoisomeric forms of trimethylmethylxyloside. Methylation of xylose with methyl sulphate followed by treatment with methyl iodide and silver oxide gave crystalline trimethyl-β-methylxyloside. As obtained by distillation the product was a mixture of the α- and β-forms, from which the latter was obtained by crystallisation from light petroleum. It had the following constants: m.p. 46°—48° C., $n_D^{25}=1{\cdot}4350$, $[\alpha]_D=-67^\circ$ (in water). In acidified methyl alcoholic solution the equilibrium value of $[\alpha]_D$ was $+49{\cdot}5^\circ$. With the object of obtaining the trimethyl-α-methylxyloside the equilibrium mixture of α- and β-methylxylosides obtained by heating xylose with acidified methyl alcohol at 100° C. for 20 hrs., was separated as far as possible, and the α-form methylated by the silver oxide method. The product was a mobile syrup, b.p. 115°—118° C. at 12 mm., $n_D^{25}=1{\cdot}4410$, and it contained about 66% of the α-isomeride. The behaviour of both the α- and β-forms on hydrolysis was distinctly anomalous. The β-form only gave about a 50% yield of trimethylxylose, together with furfural derivatives and other decomposition products. Trimethylxylose crystallised from ether in large prisms, m.p. 87°—90° C. Mutarotation in aqueous solution was so rapid that the maximum value of $[\alpha]_D$ could not be obtained. In absolute alcohol $[\alpha]_D=+74^\circ$. From trimethyl-α-methylxyloside no trace of trimethylxylose could be obtained by hydrolysis, a viscous acidic syrup only being isolated. The rate of condensation of trimethylxylose with acidified methyl alcohol is very slow as compared with the hexoses. With 0·25% acid no change in rotation was observed after 60 hrs. at 15° C., but at 70° C. equilibrium was attained in 8 hrs.—G. F. M.

Fucose; Structure of ——. E. P. Clark. J. Biol. Chem., 1922, **54**, 65—73.

The method for the preparation of fucose from seaweed has been improved. On the basis of the relationship which exists between the configuration and rotation of lactones of sugar acids (Hudson, J., 1910, 366), it is concluded from the rotation of the methyl tetronolactone obtained from fucose that the configuration assigned to fucose by Mayer and Tollens (Ber., 1907, **40**, 2440) is correct.—E. S.

γ-Methylfructoside. R. C. Menzies. Chem. Soc. Trans., 1922, **121**, 2238—2247.

Dilute solutions of fructose (lævulose) in pure methyl alcohol are rapidly converted, in presence of 0·5% of hydrogen chloride, into solutions of methylfructosides, a change which is accompanied by a change of sign in the optical rotation. The change is the most rapid of its kind hitherto encountered in the sugar group, 5% and 2·5% solutions giving the maximum positive rotation in less than 30 mins. At this point the solution was neutralised with sodium methoxide, the solvent removed, and the resulting salt extracted with dry ethyl acetate, whereby an insoluble lævorotatory syrup ($[\alpha]_D=+27^\circ$) and a soluble hygroscopic syrup having $[\alpha]_D=+25{\cdot}2^\circ$ (in ethyl acetate) were separated. That the latter was γ-methylfructoside was evident from its similarity in behaviour to other substances of the γ-type, being completely hydrolysed by cold, 0·033% hydrochloric acid and decolorising *N*/500 permanganate in 30 mins., the same time as is required by γ-methylglucoside, whilst α-methylglucoside and β-methylfructoside require 30 hrs. under similar conditions. The complete methylation of γ-methylfructoside by the silver oxide method gives a tetramethyl derivative identical with that obtained from sucrose and inulin, and the ketose residue in all three substances is therefore identical.—G. F. M.

Inulin; Identification of —— by a mycological method. A. Castellani and F. E. Taylor. Biochem. J., 1922, **16**, 655—658.

Monilia macedoniensis, Castellani, ferments inulin with the production of gas. It also ferments dextrose, lævulose, galactose, and sucrose. Inulin can be identified by utilisation of the above mould in conjunction with other fungi.—S. S. Z.

Patent.

Sugar residues [e.g., those resulting from the polarisation of sugar products]; Process of recovering litharge from ——. A. S. Ramage, Assr. to The Sugar Research Synd., Ltd. U.S.P. 1,433,034, 24.10.22. Appl., 29.1.21.

Litharge is recovered from sugar residues containing lead carbonate and organic lead salts by subjecting the mixture in continuous flow to a gradually increasing temperature, and to the action of air flowing in the contrary direction, the oxygen content of the air being gradually diminished, so that the lead content is reduced first to metallic lead, which is gradually oxidised to litharge.—J. P. O.

XVIII.—FERMENTATION INDUSTRIES.

Saccharomyces cerevisiæ; Action of ultraviolet rays on ——. R. and R. de Fazi. Giorn. Chim. Ind. Appl., 1922, **4**, 463—464.

Tests on an industrial scale have shown that yeast previously exposed for 12 hrs. to the light from a quartz mercury vapour lamp ferments brewery wort more rapidly and develops less acidity than the same yeast not subjected to this treatment. (*Cf.* E.P. 143,121; J., 1920, 499 A.)—T. H. P.

Pentoses; Fermentation of —— by moulds. W. H. Peterson, E. B. Fred, and E. G. Schmidt. J. Biol. Chem., 1922, **54**, 19—34.

Out of 25 species of moulds investigated, 16 were found rapidly to ferment both xylose and arabinose; the destruction of the pentoses was, however, somewhat less rapid than that of dextrose. *Aspergillus niger* and other species of *Aspergillus* were especially active in fermenting the pentoses; *Penicillium glaucum* was also active, but with other *Penicillia* the fermentation proceeded slowly. In agreement with results obtained by others, it was found that over 90% of the carbon of the pentose consumed could be accounted for as carbon dioxide and mycelium. No volatile acid or alcohol was produced, but a small quantity of non-volatile acid appeared to be formed.—E. S.

Wines; Determination of free and combined volatile acids in ——. P. Malvezin. Ann. Falsif., 1922, **15**, 360—362.

The author maintains, in answer to criticism, that the ether-extraction method (J., 1909, 435) is reliable; the acidity of the ethereal solution varies with the concentration of the volatile acids, and is independent of the concentration of the fixed acids. Tartaric and lactic acids do not interfere under the conditions prescribed.—W. P. S.

Wines containing sulphurous acid; Action of —— on metals. P. Grelot. Ann. Falsif., 1922, **15**, 326—330.

Wines containing sulphurous acid or bisulphite act readily on certain metals. In the case of iron, zinc, tin, and aluminium, hydrogen sulphide is evolved and the wine becomes turbid owing to the liberation of sulphur in a finely-divided state. With lead, copper, and nickel the wine remains clear an there is no evolution of hydrogen sulphide, but th metals are blackened owing to the formation of layer of sulphide on their surface.—W. P. S.

XIXa.—FOODS.

Wheat flour; Chemistry of strength of ——. H. E. Woodman. J. Agric. Sci., 1922, **12**, 231—243.

The possibility of the difference between strong and weak flours depending on differences in the proteins of the gluten were investigated. Proteins were considered identical if they exhibited identically the following three properties:—Optical behaviour when racemised by dilute alkali at 37° C. at three different dilutions; specific rotation in 70% alcohol; combining capacity for alkali as determined by titration in 80% alcoholic solution with $N/10$ sodium hydroxide, using phenolphthalein as indicator. The gliadins from weak and strong flours showed no differences, but the glutenins showed different behaviour during racemisation with alkali, indicating the possibility of two or more glutenins. The physical condition of the gluten, and consequently the shape of the loaf, also depends to a certain extent on the content of soluble salts in the flour. The proteins can be extracted with a cold 0·2% potassium hydroxide solution without alteration of their optical properties. The combining weight of gliadin is about 5000, and it is concluded that the molecule contains three or a multiple of three free carboxyl groups.—A. G. P.

Beef and mutton; Autolysis of ——. W. R. Fearon and D. L. Foster. Biochem. J., 1922, **16**, 564—571.

The processes of the post-mortem autolysis of beef and mutton are exactly parallel both at incubator temperature and at low temperatures. In the case of mutton both the initial soluble nitrogen and the soluble nitrogen when the equilibrium of the autolysis has been reached, are higher than in beef. This difference in the two kinds of muscle is probably due to the difference in structure and physical properties of the muscle and not to their chemical constitution. The above results do not throw any light on the different behaviour of beef and mutton after being frozen. After being frozen the course and degree of autolysis are greatly altered. The method of freezing and the rate of freezing are of great significance.—S. S. Z.

Goat milk; Non-protein nitrogen in ——. W. Taylor. Biochem. J., 1922, **16**, 611—612.

There was a found a correlation in a lactating goat between the output of nitrogen in the urine and the percentage of non-protein nitrogen in the milk. Both were determined by the amount of protein in the food.—S. S. Z.

Proteins; Heat coagulation of ——. W. W. Lepeschkin. Biochem. J., 1922, **16**, 678—701.

A study of the processes of denaturation and coagulation of protein. The author comes to the conclusion that denaturation is a weak hydrolysis of the protein and that coagulation is not simply a process of electrical discharge of protein particles by the ions but is also dependent on the chemical properties of the salts present.—S. S. Z.

Tryptophan-estimation in protein; Nitrogen-distribution in Bence-Jones' protein and colorimetric method for ——. E. Lüscher. Biochem. J., 1922, **16**, 556—563.

Bence Jones' protein differs from all other proteins analysed up to the present time, not only in its physical behaviour but also in its nitrogen distribution as determined by Van Slyke's method. The author proposes to use benzaldehyde instead of formaldehyde in Von Fürth's colorimetric method for the estimation of tryptophan (*cf.* J., 1921, 787 a).—S. S. Z.

Nitrogeneous metabolism of higher plants. III. Effect of low-temperature drying on the distribution of nitrogen in the leaves of the runner bean. A. C. Chibnall. Biochem. J., 1922, **16**, 599—607.

On drying the leaves of the runner bean at low temperature some of the protein is autolysed with the production of water-soluble nitrogen compounds which chiefly consist of ammonium salts, asparagine, and amino-acids. The residual protein is, however, not appreciably changed in character. The dried leaves contain enzymes which are activated by water. The presence of an asparaginase which is activated by the addition of water and which under specified conditions manifests marked synthetic activity, is indicated.—S. S. Z.

Nitrogenous metabolism of the higher plants. IV. Distribution of nitrogen in the dead leaves of the runner bean. A. C. Chibnall. Biochem. J., 1922, **16**, 608—610.

The nitrogen content of, and its distribution in, the dead leaves of the runner bean killed by a frost in the twenty-fourth week of its life are given.—S. S. Z.

Oat straw; Sugars and albuminoids of ——. S. H. Collins and B. Thomas. J. Agric. Sci., 1922, **12**, 280—286.

Oat straws, grown under various conditions, were examined for their sugar and protein content, with a view to correlating feeding value and conditions of growth. Good weather conditions at harvest are necessary to obtain high sugar content. The sugar gradually disappears after harvesting, particularly if the straw becomes damp. Exceptional care in storage is necessary to retain a high sugar content for six months. The protein content of the straw varied from 1·12 to 8·05% and was roughly proportional to the amount of nitrogen in the soil. Organic nitrogenous manures produced a greater variation in the protein content of oat straw than did artificial fertilisers. The amount of protein depended to a certain extent on the amount of grain produced. (*Cf.* J., 1920, 66 t, 82 t.)—A. G. P.

Vitamin A; Significance of —— *in the nutrition of fish.* K. H. Coward and J. C. Drummond. Biochem. J., 1922, **16**, 631—636.

During the development of the larval brown trout the high vitamin A content of the ova is utilised so that the supplies are almost exhausted. On giving food rich in vitamin A to the fish in their post-larval period they develop satisfactorily and are capable of storing the vitamin. On a diet containing adequate protein but deficient in the vitamin no such storage occurs and growth is subnormal.—S. S. Z.

Fruit; Changes which occur in the pectic constituents of stored ——. M. H. Carré. Biochem. J., 1922, **16**, 704—712.

The pectin content reaches a maximum during the process of ripening of apples and then gradually falls as the fruit becomes over-ripe. The date of picking of the fruit has no effect on the development of the pectin in either cold or ordinary storage. Protopectin—the precursor of soluble pectin—can be estimated by hydrolysing the residue with $N/20$ hydrochloric acid and then applying the calcium pectate method. Preliminary work suggests the existence of a definite relationship between the quantities of soluble pectin and protopectin constituents and that the production of soluble pectin is due to enzyme action. There is a possibility of the existence of a third soluble pectin.—S. S. Z.

PATENTS.

Oleaginous emulsifying materials, and manufacture of edible substances. Manufacture of emulsions or emulsifying ingredients or materials. E. V. Schou. E.P. (A) 187,298 and (B) 187,299, 12.1.21.

(A) An oil-soluble gelatinised oil with pronounced viscous, tough, and elastic properties is produced from oils containing linolic or linolenic acid by heating or polymerisation, with or without previous or simultaneous oxidation. Fresh oil of a suitable kind is added to the gelatinised oil and the whole stirred at a temperature of 100°—120° C. until the gelatinised oil is completely dissolved, when the blend is cooled to atmospheric temperature. The substances distilling over during the preparation of the gelatinised oil may be recovered. The product is suitable as a substitute for butter and lard, or may be added to oils or fats to increase their viscosity. (B) A sticky and elastic oleaginous material, which may be prepared as described under (A), is used as the oleaginous portion of an emulsion, either alone or dissolved in or diluted with a quantity of untreated oil. An aqueous liquid, which may or may not contain a small proportion of solid matter of a viscous or sticky character, is vigorously stirred into the oleaginous portion, and an emulsion is produced which is soluble in oil and in which the oily portion constitutes the external phase and the watery portion the internal phase.—H. C. R.

Milk product and process of making it. P. G. Kinzer, Assr. to Carnation Milk Products Co. U.S.P. 1,432,699, 17.10.22. Appl., 6.3.18.

The cream is separated from fresh milk and churned to separate the butter. The skim milk from the first separation and the buttermilk from the second separation are combined with an edible vegetable fat to form a stable emulsion.—H. H.

Coffee substitutes; Manufacture of —— from cereals and the malt of cereals. K. Lendrich. U.S.P. 1,434,297, 31.10.22. Appl., 7.1.20.

See E.P. 131,304 and 153,971 of 1919; J., 1921, 58 A, 94 A.

XIXb.—WATER PURIFICATION; SANITATION.

Water; Statistical record of Toronto ——, 1912—21. N. J. Howard. Canadian Eng., 1922, 42, 468—476.

A review is given of the laboratory work in connexion with the filtration of the water supply of the City of Toronto, which is derived from Lake Ontario. The water is treated by slow sand and drifting sand filtration and by subsequent sterilisation. Aluminium sulphate was used also to remove the large bacterial pollution of the raw water. The number of bacteria was reduced 99% by slow sand filtration and 95% by drifting sand filtration. The numbers of *B. coli* in the raw water have much increased during late years, and now 12% of the water samples treated by slow sand filtration contain *B. coli* in 1 c.c. This is not regarded as a serious matter, because the water is afterwards treated with chlorine. The view is expressd that modern practice in America regards the purification of a water supply as more practical and economical than the purification of sewage before its discharge into a stream. Along with the increase in *B. coli*, the chlorine increased from 8 to 10 parts per million. The average amount of aluminium sulphate added increased from 1 grain to 1·3 grain per gal. during the last four years, more being required in summer than in winter. The slow sand filters were more efficient in summer, on account of their greater porosity in winter weather. The dose of chlorine required varied from 0·2 part per million in winter to 0·375 part in summer. No definite reason could be given for the occasional occurrences of taste in the water. The mortality from typhoid fever decreased from 12 to 3 per 100,000 during the period.—J. H. J.

Chlorination [of water] prior to filtration. N. J. Howard. J. American Water Works Assoc., 1922, 9, 606—611. [Reprint.]

During 1921 the Toronto water supply was treated with chlorine instead of with aluminium sulphate before filtration in drifting sand filters. This was done because of the large amount of aluminium sulphate required as a result of the rapid increase in the pollution of the raw water from Lake Ontario. The chlorine was applied at the rate of 0·15—0·3 part per million, any excess being absorbed by the sand filter. The purification effected in the summer was much better than with aluminium sulphate, but not so good in winter. The use of chlorine considerably increased the volume of water which it was possible to filter daily. An iodoform taste developed in the treated water rather more frequently than when aluminium sulphate alone was employed, but no connexion could be found between the addition of the chlorine and the development of the taste. The total cost of the chlorine treatment was much less than that of the aluminium sulphate method.—J. H. J.

Taste and odour [from water]; Modern practice in the removal of ——. N. J. Howard. J. Amer. Water Works Assoc., 1922, 9, 766—782. [Reprint.]

Taste in water arising from the presence of gases and iron in solution may be removed by aeration and filtration processes. Crenothrix may be removed by aeration and filtration or by filtration alone. Algæ may be removed by chlorine or more successfully by copper sulphate; they flourish best in water of high alkalinity, and experiments showed that a sufficient reduction of the alkalinity led to their death. The cause of taste following chlorination is not definitely established. There are two kinds of taste in waters treated with chlorine: a chlorine taste and an iodoform taste, which never occur together, but odour may occur at the same time, particularly when the water temperature is above 50° F. (10° C.). In water which contains chlorine in excess of the amount necessary for sterilisation both taste and odour exist. An application of 0·175—0·225 part of chlorine per million at a temperature of 35°—45° F. (2°—7° C.) does not usually lead to complaint of taste, but as the temperature rises more chlorine must be added to get the same sterilisation effect. Standard solutions of aniline dyes were made up to match the blue colour of starch iodide, and were used at Toronto Water Works as useful indicators as to the correctness of the amount of chlorine being added. The iodoform taste appears to be due to the presence of phenols and organic matter in the water before treatment, but in certain cases there appear to be other causes. Experiments with Lake Ontario water showed that in presence of small amounts of phenol, up to 0·017 part per million, an iodoform taste developed when 0·175 part of chlorine per million was added, and persisted up to a dose of 0·65 part, when the tasto disappeared. The reverse process of adding excess of phenol to water containing chlorine was not successful in removing the taste. Treatment by the excess lime method reduced but did not remove the iodoform taste.—J. H. J.

Alkalinity of water and culture media; Estimation of ——. H. Noll. Z. Hyg. u. Infkt. Krankh., 1922, **96**, 172—190. Chem. Zentr., 1922, **93**, IV., 1003—1004.

The estimation of alkalinity by direct and indirect titration, using methyl orange, gives good results. The indirect method after expelling carbon dioxide by boiling is more accurate, although the cause of the difference in the methods has not been ascertained. The limiting sensitiveness is about $N/1000$ solutions. In titrating ferruginous waters immediately after sampling, the carbonates of iron cause too high a figure for the alkalinity, and the estimation should be delayed until the iron has separated out. Humates and silicates are estimated as carbonates. In using phenolphthalein in the indirect method, the titre of the phenolphthalein should be determined and the same quantity of it used in each titration. Good alkalinity figures are obtained with ferruginous waters if the iron is wholly or partially precipitated. Humates do not affect the alkalinity when phenolphthalein is used; silicates are recorded as carbonates. Azolitmin gives similar results to phenolphthalein but the colour change is inferior. The alkalinity of culture media is best determined by spotting out on litmus paper. Phenolphthalein is only suitable for clear liquids. The difference between the neutral points of litmus and phenolphthalein is due to carbonates and not to phosphates. The estimation of phosphate in peptone extracts and nutrient media is most satisfactorily carried out by the molybdate method. The phosphate in nutrient media is partially removed by neutralisation and filtration.—A. G. P.

Fungicidal properties of certain spray fluids. E. Horton and E. S. Salmon. J. Agric. Sci., 1922, **12**, 269—279.

The fungicidal properties of a number of solutions towards the conidial stage of *Sphaerotheca Humuli* on young hop leaves, were determined. Disodium arsenate solution (0·096 % As_2O_5) was fungicidal but killed patches of leaf cells beneath the mildew patches; with a solution containing 0·02 % As_2O_5 the latter injury was not observed. Trisodium arsenate with 0·77 % As_2O_5 was fungicidal. Dicalcium arsenate containing above 0·024 % As_2O_5 and tricalcium arsenate containing above 0·02 % As_2O_5 were fungicidal. Calcium polysulphide (0·11 % of polysulphide sulphur) was fungicidal, but the following among its constituents were harmless: calcium sulphate, sulphite, thiosulphate, and hydroxyhydrosulphide.—A. G. P.

Patents.

Filtering apparatus [for water]. W. Paterson. E.P. 187,259, 26.4.21.

A manifold pipe system for the collection of filtered liquid and for the distribution of compressed air and wash water for cleansing the filter bed is superposed on a channel or tube, constituting the main collecting or distributing header, of which the upper surface is substantially flush with the bottom of the filter bed. The pipes are each connected with the header by a T-piece and are clamped in position. —H. H.

Chlorine gas [for water purification]; Method of producing ——. G. N. Blanchard. U.S.P. 1,430,785, 3.10.22. Appl., 21.7.20. Renewed 31.5.22.

A current from a transformer is conducted through cells containing salt water. The strength of the current is co-ordinated with the flow of water to be purified, so that the chlorine is produced in a fixed proportion to the flowing water.—J. H. J.

Sewage treatment. Dorr Co., Assees. of H. W. Morgan. E.P. 171,361, 26.7.21. Conv., 10.11.20.

See U.S.P. 1,392,197 of 1921; J., 1921, 868 A.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Nicotine; Determination of —— *in tobacco and tobacco smoke.* M. Popp and J. Contzen. Chem.-Zeit., 1922, **46**, 1001—1002.

The nicotine was determined in eight kinds of cigar and pipe tobacco and in their smoke. The nicotine in the tobaccos was determined by Rasmussen's extraction method (J., 1915, 300) and by Mach's distillation method (Landw. Vers.-Stat., **45**, 40). The results obtained by the two methods agreed well with one another. To determine the nicotine in the smoke, weighed quantities of the tobacco were smoked in a holder or pipe and the smoke passed through five wash-bottles filled with 10 % hydrochloric acid, which after absorption was completed was made up to 1000 c.c. An aliquot part of this solution was made alkaline with sodium hydroxide and steam-distilled. The distillate was precipitated with silicotungstic acid. Other bases such as pyridine are also precipitated, but if acetic acid is present small quantities of pyridine are not precipitated. The total nicotine in the cigars and pipe tobaccos examined varied from 0·31 % to 2·21 %. The smoke from these tobaccos contained from 0·20 % to 1·05 % of nicotine.—H. C. R.

Alkaloids; Use of the newer indicators in titrations of ——. W. J. McGill. J. Amer. Chem. Soc., 1922, **44**, 2156—2160.

The indicators generally used in the titration of morphine, atropine, and quinine give results which are not nearly so accurate as should be obtained. In the case of morphine the average error using methyl red is 1·4 %, whereas bromophenol blue gives an average error of only 0·5 %, and in some cases this is as low as 0·1 %. The best indicator for quinine is bromocresol purple, whilst for cinchona residues, either cochineal, methyl red, or bromocresol purple may be used. Cochineal and methyl red give low results with morphine, atropine, and mydriatic alkaloid residues, whilst bromophenol blue gives satisfactory results in all these cases. Methyl red is the most satisfactory indicator for strychnine. —J. F. S.

Liquorice extract; Detection of extract of Atractylis gummifera in ——. U. Giuffrè. Giorn. Chim. Ind. Appl., 1922, **4**, 460—461.

Adulteration of liquorice extract with extract of *Atractylis gummifera*, which contains the poisonous glucoside, potassium atractylate, may be detected as follows. Fifty grms. of the extract is dissolved in a little water and the dense solution mixed with about 500 c.c. of alcohol, treated with animal charcoal, allowed to stand, filtered, and reduced by distillation to a small volume. After diluting with a little water, the liquid is made distinctly alkaline with sodium hydroxide, boiled for half an hour in a reflux apparatus, cooled, acidified with dilute sulphuric acid, and distilled to small volume in a current of steam. The presence in the distillate of valeric acid, one of the products of the alkaline hydrolysis of potassium atractylate, is indicated by the odour. The residue from the distilling flask is saturated with ammonium sulphate, boiled for 15 mins. with alcohol and animal charcoal, and filtered. Concentration of the filtrate and subsequent dilution with water result in the precipitation of another hydrolytic product, atractyligenin, which is purified by further treatment with alcohol and charcoal. The cold residue formed on evaporation of a drop of the filtered liquid on a watch-glass is treated with a few drops of concentrated sulphuric acid, which gives a yellowish coloration changing to carmine on addition of a little piperonaldehyde, vanillin, or other aromatic hydroxyaldehyde in aqueous solution.—T. H. P.

Carrageen (Chondrus crispus). III. Constitution of the cell wall. B. Russell-Wells. Biochem. J., 1922, 16, 578—586.

The chemistry of hot and cold extracts of carrageen was studied. Both extracts contain pentose radicles and calcium and ammonium ethereal sulphates. The ash also contains calcium, magnesium, sodium, potassium and traces of iron. Pectic radicles are not present in either extract. The cold extract contains a dialysable organic substance. On oxidation the cold and hot extracts yield mucic, oxalic, and tartaric acids; more mucic but less oxalic acid is obtained from the cold than from the hot extract. The extracted residue of carrageen contains cellulose. There are indications that *Ceramium rubrum* also contains ethereal sulphates.—S. S. Z.

System o- and p-toluenesulphamides. A. F. Dobrjanski. J. Russ. Phys.-Chem. Soc., 1920, 52, 139—144.

During the manufacture of saccharin treatment of the mixed *o*- and *p*-toluenesulphonic chlorides with ammonia yields a mixture of the corresponding sulphamides of which a portion, melting at 108° C., remains non-separable. This portion agrees in composition with the eutectic mixture of the two sulphamides, so that separation by fractional precipitation should be impossible. The acicular crystals, m.p. 120° C., described by Fahlberg, represent a mixture of the two isomerides in equal proportions, but the melting point curve shows no distectic point and gives no indication of the formation of a molecular compound; the crystals of the two components are readily distinguished in the mixture under the microscope.—T. H. P.

Alanine; Identification of —— by crystallo-chemical analysis. I. S. Jaitschnikov. J. Russ. Phys.-Chem. Soc., 1920, 52, 145—147.

Since optically-active alanine often yields opalescent solutions incapable of polarimetric investigation, the author has made crystallographic measurements which may be used to identify this substance. —T. H. P.

[*Chaulmoogra esters, etc.*] *Manufacture of certain drugs for the treatment of leprosy.* G. A. Perkins. Philippine J. Sci., 1922, 21, 1—16.

The use and method of administration of chaulmoogra and other oils and their derivatives in the treatment of leprosy is discussed. A new method for the preparation of the ethyl esters of the fatty acids of chaulmoogra oil is described. 10 kg. of crude oil is mixed with 13 l. of 95% ethyl alcohol and 750 c.c. of 93% sulphuric acid, and heated under a reflux condenser for 20 hours. The reaction product is washed with an equal volume of water and then with dilute soda till neutral. The separated oil is dried and distilled in small quantities in a continuous still under reduced pressure. The distillate is vigorously agitated with a current of steam for 2 hrs. to remove irritating volatile impurities, and then dried, filled into bottles, and sterilised. The yield amounts to 90—95% of the original weight of the oil taken. Hydrogen chloride can be used instead of sulphuric acid as a catalyst, but no advantage is apparently gained. The preparation of sodium "gynocardate" by neutralisation of a fraction of the fatty acids of chaulmoogra oil melting at 48° C., of sodium "morrhuate," a similar preparation made from cod-liver oil, and of the cod-liver oil esters is also described.—G. F. M.

ββ'-Dichlorodiethyl sulphide; Hydrolysis of ——. Synthesis of divinyl sulphide and the preparation of a non-vesicant isomeride of ββ'-dichlorodiethyl sulphide. S. H. Bates and S. A. Nickelson. Chem. Soc. Trans., 1922, 121, 2137—2139.

ββ'-Dichlorodiethyl sulphide when hydrolysed with 20% alcoholic potassium hydroxide gives about 26% of its weight of a light oil having a garlic-like odour and boiling at 85°—86° C. Although this b.p. does not agree with that given by Beilstein for divinyl sulphide there is no doubt that this is the substance actually formed, according to the equation

$$S(CH_2CH_2Cl)_2 + 2KOH \dashrightarrow 2KCl + 2H_2O + S(CH{:}CH_2)_2,$$

and the b.p. given in the literature is incorrect. The oil has sp. gr. at 15° C. 0·9174, and when freshly distilled the vapour density is practically normal, but when kept for 48 hrs. the substances polymerises to an opaque jelly. Treated with dry hydrogen chloride in the cold, 2 mols. are added on with formation of αα'-dichlorodiethyl sulphide, a colourless liquid with a pungent and objectionable odour, but devoid of vesicant properties. It boils at 58·5°—59·5° C. at 15 mm., but when distilled under atmospheric pressure, decomposes with liberation of hydrogen chloride. Like divinyl sulphide it reacts violently with nitric acid.—G. F. M.

Urea; Decomposition of —— by sodium hypobromite in alkaline solution, and improved procedure for the estimation of urea by this means. E. A. Werner. Trans. Chem. Soc., 1922, 121, 2318—2325.

An estimation of urea, based on the evolution of total nitrogen by hypobromite, including that fixed during the reaction as alkali cyanate, consists in the addition of the urea solution to a small excess of alkali hypobromite contained in a nitrometer. After 20 mins. the volume of gas evolved is recorded and the gas is then expelled from the nitrometer. Sulphuric acid (1 in 5 pts. of water) is added to the residual liquid until, after mixing, the permanent presence of free bromine is shown. Carbon dioxide is liberated which is not expelled. After 15 mins. 30% sodium hydroxide is added in excess, together with a small additional quantity of hypobromite. After complete absorption of the carbon dioxide, the volume of nitrogen produced is added to that recorded in the first stage. An error of about 0·5% on the total nitrogen, owing to the fixation of a trace of the nitrogen as nitrate, results. Suppression of the formation of cyanate by the generation of the hypobromite *in situ* results in a violent reaction, in which traces of carbon monoxide, increasing with the alkalinity of the reagent, appear in the evolved gas. Other conditions being equal, the addition of dextrose leads to the formation of carbon monoxide and markedly increases the proportion of nitrogen fixed as cyanate. This is also the case when the reaction is slowed down by the use of neutral hypobromite.—P. V. M.

Aqueous alcohol; Selective solvent action by the constituents of ——. R. Wright. Trans. Chem. Soc., 1922, 121, 2251—2256.

The effect of the three solutes, sucrose, benzyl alcohol, and glycerol on the partial vapour pressures of 38% aqueous alcohol has been investigated. Sucrose, soluble only in water, and glycerol, soluble both in water and alcohol, raise the vapour pressure of the alcohol and lower that of the water. Benzy alcohol, soluble only in alcohol, lowers the vapou pressure of each component of the solvent. Thu solids, soluble in one component only, lower th vapour pressure of that constituent of the solven in which they are soluble in the pure state. Thes conclusions are supported by freezing-point determinations which show, further, that glycerol, miscible with both components, has probably a greate attraction for water than for alcohol.—P. V. M.

Terpene present in the essential oil of Andropogon iwarancusa, Jones; Constitution of the ——. J. L. Simonsen. Trans. Chem. Soc., 1922, 121, 2292—2299.

The terpene, obtained by steam distillation of the grass, had the following constants: b.p. 165·5°—167° C. at 707 mm., sp. gr. at 30° C. 0·8552, n_D^{30} = 1·474, $[\alpha]_D^{30} = +62·2°$. On oxidation in neutral acetone solution with permanganate it gives a saturated liquid keto-acid, $C_{10}H_{16}O_3$, isomeric with pinonic acid. Since sodium hypobromite converts this acid into a dibasic acid, $C_9H_{14}O_4$, which on treatment with aqueous hydrobromic acid at 100° C. is further converted into homoterpenylic acid, and since the original terpene on saturation with hydrogen chloride at 0° C. yields a mixture of dipentene and sylvestrene derivatives, it is considered to be *d*-Δ^4-carene. Δ^3-Carene has already been identified in the oleo-resin of *Pinus longifolia* (J., 1920, 581 a), and as would be expected it has a normal molecular refractivity, whilst the terpene in question shows a considerable exaltation.—G. F. M.

Patents.

Dialkylaminoalkyl compounds; Process of preparing aliphatic ——. Farbw. vorm. Meister, Lucius, und Brüning. E.P. 169,185, 15.8.21. Conv., 17.9.20. Addn. to 167,781 (J., 1922, 877 a).

The condensation described in the main patent can be carried out by causing an alkali hydroxide to act on a mixture, in molecular proportions, of a halogenalkyldialkylamine and a substance of the general formula, R.CO.CHR'X, such as ethyl acetoacetate. Further, a purer product is obtained if the reaction mixture is mixed with benzene and extracted with ammonia, before drying and distilling. *Example.* 57—58 pts. of powdered potassium hydroxide is gradually added to a mixture of 136 pts. of chloroethyldiethylamine and 130 pts. of ethyl acetoacetate. After cooling the product is stirred with benzene, the benzene solution shaken with ammonia, dried, and fractionally distilled. The ethyl diethylaminoethyl acetoacetate thus obtained boils at 130°—132° C. at 10 mm.—G. F. M.

Colloidally soluble substances and suspensions or emulsions; Manufacture of ——. L. Lilienfeld. E.P. 173,230, 20.12.21. Conv., 21.12.20. Addn. to 156,725 (J., 1922, 686 a).

By heating a solution of a water-soluble alkyl or aralkyl derivative of a carbohydrate of the form, $n(C_6H_{10}O_5)$, containing another colloidal substance in solution, suspension, or emulsion, a precipitate is formed, which, after removing the impurities or by-products by washing with hot water, can be either re-dissolved in cold water or dried. This method gives a simple and effective means of preparing colloidal solutions, suspensions or emulsions of certain metals and non-metals, either through their salts or by reducing their oxides, or of metal compounds by the interaction of the respective components in an aqueous solution of a water-soluble alkyl derivative of a carbohydrate.—S. G. U.

Alcohols; Manufacture of ——. Badische Anilin- u. Soda-Fabrik. E.P. 175,238, 15.8.21. Conv., 10.2.21. Addn. to 158,906.

See U.S.P. 1,410,223 of 1922; J., 1922, 347 a. Copper catalysts are used which are prepared, at low reduction temperatures, from copper salts or compounds which have been formed at temperatures below that of red heat by methods other than precipitation.

Thymol; Manufacture of synthetic ——. M. Phillips; dedicated to the people of the United States. U.S.P. 1,432,298, 17.10.22. Appl., 25.2.22.

Cymidinesulphonic acid is diazotised, the diazo-compound being then reduced with sodium bisulphite to cymylhydrazine-3- or 5-sulphonic acid; by oxidation with copper sulphate or ferric chloride cymene-3-sulphonic acid is obtained, the sodium salt of which on fusion with sodium hydroxide or potassium hydroxide yields thymol.—D. F. T.

Chlorinated derivatives of hydrocarbons; Manufacture of ——. G. T. Koch, Assr. to Ohio Fuel Supply Co. U.S.P. 1,432,761, 24.10.22. Appl., 4.5.20.

Liquid paraffin hydrocarbons are treated with chlorine gas in the presence of finely-divided, activated carbon.—D. F. T.

Esters and materials containing esters; Process for the production of —— from olefines. S. B. Hunt. E.P. 173,786, 30.6.20.

See U.S.P. 1,365,052 of 1921; J., 1921, 162 a.

p-Cymol; Manufacture of ——. G. Stalmann. U.S.P. 1,433,666, 31.10.22. Appl., 4.9.19.

See E.P. 142,738 of 1919; J., 1920, 501 a.

Aromatic derivatives [alkylamides of sulphonic acids]; Manufacture of ——. W. Bader and D. A. Nightingale. U.S.P. 1,433,925, 31.10.22. Appl., 18.6.21.

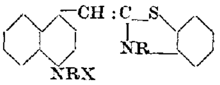
See E.P. 167,941 of 1920; J., 1921, 749 a.

Alcohol-ether mixtures. E.P. 187,051–2. *See* IIa.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Cyanine Dyes. VI. Dyes containing a quinoline and a benzothiazole nucleus. Thioisocyanines. W. T. K. Braunholtz and W. H. Mills. Chem. Soc. Trans., 1922, 121, 2004—2008.

A series of photosensitising dyestuffs is described intermediate between the thiocyanines (J., 1922, 365 a) and the isocyanines in that they contain one quinoline and one benzothiazole nucleus. They are obtained by the action of alcoholic sodium hydroxide on a mixture of a quinoline alkyliodide and a 1-methylbenzothiazole alkyliodide. This method of preparation corresponds exactly with that of the isocyanines, with which substances they show a close relationship in properties, and their constitution is therefore considered to be represented by the formula



These compounds, to which the name thioisocyanines is given, form bright red iodides and their alcoholic solutions show a pair of overlapping absorption bands in the green and bluish-green at λ 5000—5100 and about λ 120—150 shorter. They are powerful photosensitisers for the green, giving an extra sensitisation to the gelatinobromide plate extending to about λ 5800. The detailed preparation of 2.1'-diethylthioisocyanine iodide from quinoline ethiodide and 1-methylbenzothiazole ethiodide, of 5-methyl-2.1'-diethylthioisocyanine iodide, of 5.6'.1'-trimethyl-2-ethylthioisosyanine iodide, and of several other derivatives is described.—G. F. M.

Patents.

Photographic film; Antistatic ——. A. F. Sulzer, Assr. to Eastman Kodak Co. U.S.P. 1,432,366–7, 17.10.22. Appl., 21.2.21.

A film support carries on one side a photographically sensitive layer and on the other a layer comprising (a) an ether of cellulose or (b) a cellulose ether and cellulose acetate.—W. C.

Photographic film. A. F. Sulzer, Assr. to Eastman Kodak Co. U.S.P. 1,432,368, 17.10.22. Appl., 21.2.21.

The film consists of a sensitive coating on an anti-static hygroscopic nitrocellulose support which carries, on the opposite side to the sensitive layer, a non-sweating insoluble antistatic coating.—W. C.

Photographic developer. W. Dieterle. U.S.P. 1,432,542, 17.10.22. Appl., 25.3.21.

A photographic developer consists of a sulpho-acid of a derivative of aminophenol dissolved in a solution of caustic alkali.—A. R. P.

[*Photographic*] *transparencies on glass, transfer images etc.* Farbenfabr. vorm. F. Bayer und Co., Assees. of A. von Biehler. G.P. 357,720, 8.2.21.

Sensitive transferable material prepared as described in G.P. 357,011 (J., 1922, 917 A), is rolled in the wet state with gelatin on to a plate of glass or other suitable material coated with hardened gelatin in the usual way, and after drying has commenced is separated from the support. The product possesses a protective film which renders it proof against damp and mechanical action.—W. C.

[*Photographic*] *transfer films.* Farbenfabr vorm. F. Bayer und Co., Assees. of A. von Biehler. G.P. 358,285, 16.12.20. Addn. to 357,011 (J., 1922, 917 A).

Softening materials, *e.g.*, triphenyl phosphate, triacetin, etc., are added to the substratum or to the film of cellulose compounds carried by it, and as an intermediate support is used a material having a definite structure, *e.g.*, stamped paper.—W. C.

XXII.—EXPLOSIVES; MATCHES.

Sporting cartridges; Use of petards of black powder in —— charged with smokeless powder. N. Bagajoli and G. De Florentiy. Giorn. Chim. Ind. Appl., 1922, 4, 457—458.

With the object of diminishing the pressures developed in sporting guns by cartridges of smokeless powder without lowering appreciably the velocity generated, it is suggested that very small petards, containing a few centigrams of fine grained black powder, be introduced into the cartridge case in immediate contact with the cap. The results of experiments made with various commercial powders show that, in some cases, the pressure may be reduced in this way by more than 220 kg. per sq. cm.—T. H. P.

Patents.

Explosive. T. L. Davies. U.S.P. 1,432,321, 17.10.22. Appl., 25.4.22.

An explosive composition including the tetranitrate, tetrabenzoate, and cinnamate of pentaerythritol as ingredients.—H. C. R.

Nitrocellulose powder grains; Coating for ——. T. L. Davis. U.S.P. 1,432,322, 17.10.22. Appl., 25.4.22.

The grains are coated with a heterocyclic nitrogen compound.—H. C. R.

Propellants; Process for making —— from ammonium nitrate and carbonaceous matter. Ver. Chem. Fabr. Mannheim. G.P. 334,546, 8.12.16.

Carbonaceous matter is used which forms homogeneous melts with ammonium nitrate. The melts are allowed to cool in thin sheets so as to obtain the propellant in a foliated form or as powder. The grinding of the charcoal and incorporation with ammonium nitrate under edge-runners are thus avoided and the manufacture of the propellant simplified.—H. C. R.

Propellants; Process for making —— from ammonium nitrate and carbonaceous matter. Rhenania, Ver. Chem. Fabr. A.-G. Zweigniederlassung Mannheim. G.P. 351,206, 13.6.17. Addn. to 334,546 (*cf. supra*).

The mixture of ammonium nitrate and carbonaceous matter is melted continuously in a vertical or inclined, steam-heated, jacketed vessel of small capacity, and is then cooled by means of a revolving chilled drum which dips into the homogeneous molten mass and from which the cooled propellant is removed in the form of thin leaves by means of a scraper. The decomposition of the mixture is thus avoided.—H. C. R.

XXIII.—ANALYSIS.

Platinum thermometers and resistance coils; Construction of ——. J. R. Roebuck. J. Opt. Soc. Amer., 1922, 6, 865—874.

In order to eliminate as completely as possible the zero shift in platinum thermometers, more especially such as are used at temperatures not exceeding 300° C., the platinum resistance wire is wound non-inductively in a helical groove cut in a cylinder of beeswax and resin, in which four radial arms of mica carried on a metal spool are embedded. Before winding, the wire is annealed at a dull red heat. After winding is completed the ends of the wire are joined to their respective leads by silver solder, and the cylinder of wax and resin removed by means of hot turpentine, which is then removed by a volatile solvent such as carbon tetrachloride. The cylindrical helix of wire is heated gradually within a hard glass tube and the annealing completed by passing a small current through the wire. Conduction along the leads is reduced by threading the wire through holes in short metal cylinders separated from each other by non-conductors. The leads are insulated from the cylinders by thin glass tubes. In the construction of resistance coils for use with the thermometer, manganin wire is wound non-inductively on a cylinder of paraffin wax, in which is embedded a brass cross, extending the length of the cylinder and each arm of which carries a strip of mica bent so as to form part of the cylindrical surface. The edges of the strips do not meet, so that the wire may spring in and out as required by temperature conditions. The coil is annealed by heating at 135° C. and is then mounted in a container with acid-free dry kerosene.—J. S. G. T.

Colorimeter. E. Moreau and A. Bonis. Ann. Falsif., 1922, 15, 357—360.

The apparatus consists of two similar graduated cylinders mounted side by side on a suitable stand; one of these contains the coloured solution under examination and the other the standard or comparison solution, which is admitted from a tapped funnel attached to a side tube at the bottom of the cylinder.—W. P. S.

Gases; New apparatus for washing ——. A. Ernesta. Chem. Listy, 1922, 16, 274—276.

The tube leading the gas to be purified into the washing vessel is surrounded by a long spiral; this increases the contact of the gas with the liquid and ensures efficient washing. The tube leading in the gas and the spiral are easily removed from the vessel.—W. T.

Filtration; Quantitative determination of the velocity of ——. A. Steiner. Kolloid-Zeits., 1922, 31, 204—209.

The velocity of filtration of suspensions and colloid solutions may be measured as follows: The top of a burette is widened so that it will take a cork through which the stem of a filter funnel passes, and a side tube is attached near to the top but just above the graduations. The side tube is connected through a manometer and a safety flask with a water pump. The volume of liquid collected in the burette is read at intervals and a filtration curve plotted. For comparative measurements the pressure of the filtration must be kept constant. The velocity of filtration may be used in the investigation of changes of hydration and of the effect of the addition of electrolytes.—J. F. S.

Cobalt; Separation of —— by means of phenylthiohydantoic acid. H. H. Willard and D. Hall. J. Amer. Chem. Soc., 1922, 44, 2219—2226.

COBALT may be quantitatively separated from arsenic, uranium, vanadium, titanium, tungsten, molybdenum, zinc, manganese, chromium, aluminium, magnesium, and calcium by precipitation with phenylthiohydantoic acid in slightly ammoniacal solution. In the presence of iron the precipitate is rarely free from this impurity, and usually contains 1—5 mg. regardless of the amount originally present. This does not, however, interfere with the volumetric estimation of cobalt. Nickel is always partially precipitated. The cobalt precipitate has not a definite composition and is probably mixed with some cobalt sulphide, thus making it necessary to convert the cobalt into some other more definite form. To separate cobalt from iron the procedure is as follows: a solution containing 1 g. of iron and 25 mg. of cobalt in 300 c.c. is treated with 8 g. of citric acid in a 500 c.c. Erlenmeyer flask, neutralised with ammonia (sp. gr. 0·90) and 5 c.c. excess added. The solution is heated to 35° C., 0·7—1·0 g. of phenylthiohydantoic acid dissolved in 30 c.c. of water or alcohol added, and the mixture shaken vigorously for several minutes. The cobalt is precipitated and after boiling for several minutes the precipitate may be filtered. Manganese may be separated in the same way as iron. The other metals including zinc are separated as above but a 10 c.c. excess of ammonia is used, and the solution boiled and stirred for some time to complete the precipitation. For the preparation of phenylthiohydantoic acid, $C_6H_5.N{:}C(NH_2).S.CH_2.COOH$, a mixture of 189 g. of monochloroacetic acid and 152 g. of ammonium thiocyanate is treated with 186 g. of aniline and 930 c.c. of methyl or ethyl alcohol, and the mixture is boiled for several hours under a reflux condenser. After allowing to settle, the clear liquid is separated and allowed to crystallise. The crystals are washed with water, dried, and recrystallised from alcohol and from water. The yield, including a second crop of crystals obtained after heating the mother liquor and insoluble matter for a further period under a reflux condenser, is 60—70%.—J. F. S.

Cobalt; Gravimetric determination of ——. H. H. Willard and D. Hall. J. Amer. Chem. Soc., 1922, 44, 2226—2231.

ALTHOUGH pure cobalt nitrate may be accurately ignited to the oxide, Co_3O_4, and the latter reduced by hydrogen to the metal, the oxide obtained by the ignition of the phenylthiohydantoic acid precipitate (*cf. supra*) contains a little sulphate. If the oxide obtained in this ignition is empirically assumed to be Co_2O_3 the results for cobalt are fairly good. The ignition of cobalt sulphate at 550° C. is the most accurate method for the determination of cobalt, but when this method is applied to the phenylthiohydantoic acid precipitate the results are usually slightly high and the sulphate is not completely soluble in water. The electrolytic estimation of cobalt is very satisfactory when the proper conditions and precautions are observed. Precipitation as cobalt ammonium phosphate followed by ignition to cobalt pyrophosphate is less accurate than the preceding methods.—J. F. S.

Cobalt; Volumetric determination of ——. [Determination of cobalt in alloy steels.] H. H. Willard and D. Hall. J. Amer. Chem. Soc., 1922, 44, 2237—2253.

VOLUMETRIC methods are the most reliable for the determination of cobalt. The most accurate method involves the oxidation of cobalt to cobaltic hydroxide in strongly alkaline solution by means of a perborate or hydrogen peroxide, followed by its reduction to a cobaltous salt. The reduction may be accomplished by the following methods: (1) addition of potassium iodide in acid solution, the iodine liberated being titrated with sodium thiosulphate; in this method iron must be absent; (2) adding the cobaltic hydroxide to an acid solution of ferrous sulphate, the excess of which is titrated with potassium permanganate; an empirical factor must be used in the calculation here; (3) addition of a strongly acid solution of stannous chloride, the excess of which is titrated with iodine, iodate, bromate, or bichromate solution; the last solution, titrated electrometrically, is especially recommended; if iron is present iodine will oxidise it quantitatively only in neutral solution; (4) addition of titanous sulphate, the excess of which is titrated with permanganate; since titanium hydroxide decomposes water with the liberation of hydrogen, the alkaline solution must be first almost completely neutralised. The presence of nickel does not interfere with these titrations, but the oxidation is incomplete if more than 7 mg. of iron is present. In the presence of a large excess of potassium bicarbonate, cobalt is oxidised by hydrogen peroxide to a green trivalent compound, which is reduced in the presence of pyrophosphate by ferrous sulphate, the excess of which is titrated with permanganate after acidifying with sulphuric acid. Iron and manganese in small amounts do not interfere with this method, but the principal source of error is in the removal of excess peroxide, without decomposing the cobalt compound. The methods described in this and preceding papers (*cf. supra*) were applied to the analysis of steels containing chromium, tungsten, vanadium, and cobalt. The procedure was as follows: A sample (0·7 g.) was treated with 40 c.c. of hydrochloric acid (sp. gr. 1·1) and the tungsten separated as a black powder, 1—2 c.c. of 85% phosphoric acid and 3 c.c. of nitric acid were added cautiously, and the solution kept hot until everything had dissolved. Seven grams of citric acid was added, and the solution neutralised with ammonia (sp. gr. 0·91) and an excess of 6 c.c. added. To the hot alkaline solution 1 g. of phenylthiohydantoic acid in 30 c.c. of hot water was added with constant stirring. The cobalt precipitated at once and the solution was boiled for a few minutes with vigorous stirring. The precipitate was filtered, washed, dried, ignited with potassium pyrosulphate, and dissolved in water. The cobalt was oxidised with perborate and reduced with standard stannous chloride, the excess of which was titrated with bichromate. Four independent determinations gave 3·77, 3·75, 3·74, and 3·75%, whilst the cobalt content found by the nitroso-β-naphthol method, after the removal of tungsten and iron, was 3·84%.—J. F. S.

Copper; Separation of —— by means of phenylthiohydantoic acid. H. H. Willard and D. Hall. J. Amer. Chem. Soc., 1922, 44, 2253—2254.

IN solutions slightly acidified with acetic acid, phenylthiohydantoic acid precipitates quantitatively copper, lead, mercury, cadmium, bismuth, and antimony, whilst arsenic, tin, and metals not precipitated by hydrogen sulphide are not precipitated. The copper precipitate when ignited to oxide contains sulphate, and ordinarily is too unstable to be weighed directly. The estimation of the copper in the precipitate is best carried out by fusing with potassium pyrosulphate, dissolving in water, and electrolysing the solution. The bismuth and antimony compounds are soluble in alcohol. Copper is separated from the metals of the iron and zinc groups by adding 7 g. of citric acid for each gram of metal precipitable by ammonia present, neutralising with ammonia and adding 5 g. of glacial acetic acid. The solution is made up to 300—400 c.c., heated to the boiling point, and treated with 0·5 g. of phenylthiohydantoic acid dissolved in a little hot water, then dilute ammonia is added until a yellow precipitate commences to form. The solution is boiled, and if the copper is entirely precipitated the precipitate rises to the top and leaves a clear solution below. If this does not happen, a little more ammonia is added, but the precipitate may then turn brown due to the formation of sulphide. The precipitate is filtered hot, washed with hot water, and treated as above. The method is excellent for small quantities of copper.—J. F. S.

Copper; Volumetric determination of —— by means of sodium nitroprusside. G. Loret. Ann. Falsif., 1922, **15**, 354—356.

The dilute nitric acid solution of the copper salt (containing not more than 0·1 g. of copper) is diluted to 100 c.c., neutralised with ammonia, then acidified slightly with nitric acid, treated with 10 c.c. of $N/10$ sodium nitroprusside solution (14·895 g. per l.), diluted to 200 c.c., and filtered; 100 c.c. of the filtrate is treated with 20 c.c. of $N/10$ silver nitrate solution, the mixture is filtered after a few mins., and 100 c.c. of this filtrate is titrated with $N/10$ thiocyanate solution, using iron alum as indicator. The number of c.c. of the thiocyanate solution used is multiplied by 12·6 to obtain the percentage of copper present. Silver, nickel, cobalt, and halogens must not be present in the copper solution.
—W. P. S.

Selenium; Determination of ——. L. Losana. Giorn. Ind. Appl., 1922, **4**, 464—466.

Selenium may be determined by the method given for estimating sulphur (J., 1922, 614 A, 691 A) if a somewhat larger excess of iron is used and air is excluded as completely as possible during the reduction. The decomposition of the selenide is effected with hydrochloric acid of at least 40—50% strength and best in a stream of hydrogen purified by permanganate, although carbon dioxide may be used. The substance taken should contain not more than 0·05 g. of selenium. Should both sulphur and selenium be present, the gases obtained on decomposing the mixed sulphide and selenide are passed in a slow current of hydrogen through the absorption tubes, the first containing zinc chloride solution acidified with just enough hydrochloric acid to prevent precipitation of zinc sulphide, and the second zinc acetate solution. Any hydrogen sulphide fixed by the first tube may be expelled by immersing this tube in a bath at 40°—50° C. and passing a rapid stream of gas through the apparatus. When the proportion of sulphur is small compared with that of selenium, a second small tube filled with zinc chloride should be placed between the other two tubes. The chloride and acetate solutions are treated separately with excess of iodine solution and titrated with thiosulphate. Penetration of selenium to the zinc acetate solution will be rendered evident by the precipitation of red selenium by the iodine solution.—T. H. P.

Volumetric methods; New ——. [*Determination of sulphate, lead, acids, and ammonia.*] K. Jellinek and H. Ens. Z. anorg. Chem., 1922, **124**, 185—202.

The known volumetric methods of determining sulphate are unsuitable on account of the filtrations involved. The authors have worked out the following method. Excess of barium nitrate is added to a sulphate solution, then excess of potassium chromate is added, and this excess determined by titrating in a barium solution until the disappearance of the yellow colour. The error by this method is 0·3%. The use of silver salt as an indicator is not possible because the solubilities of silver and barium chromates are very near. The following is given as a volumetric method of estimating lead; excess of chromate is added to a lead salt, a little silver nitrate is then added, and the excess of chromate is determined by titrating against a lead salt until the disappearance of the reddish-brown silver chromate. This latter method can also be employed for the indirect estimation of sulphate. Titration of metals against arsenates and arsenites gave no positive results. The authors suggest the use of a copper solution as an indicator in acidimetry, the alkali being added until the precipitated hydroxide makes its appearance.—W. T.

Alkali carbonates [*and hydroxide*]*; Estimation of —— in presence of phenolphthalein.* [*Determination of carbon in steel.*] M. Bonnier. Comptes rend., 1922, **175**, 765—767.

Errors in titrating alkali hydroxide in presence of alkali carbonates due to the instability of the bicarbonate, on the formation of which the end-point depends, may be eliminated by dilution of the hydroxide solution to $N/100$. Six drops of phenolphthalein indicator should be used and the acid added 1 c.c. at a time, the solution being stirred after each addition. When the colour begins to disappear, the acid should be added drop by drop. In estimations of carbon in steel by conversion into carbon dioxide which is absorbed by standard sodium hydroxide, this method is stated to give results which are accurate to 0·1 mg. In a steel containing 0·1% of carbon, for the analysis of which a sample of 1 g. of the metal is taken, this corresponds to an error of ±1 in the second decimal place.—H. J. E.

Magnesium; Volumetric estimation of —— in presence of potassium salts. A. Vürtheim. Chem. Weekblad, 1922, **19**, 461—462.

Precht's method (Z. anal. Chem., 1879, 18, 438) of addition of excess of alkali free from carbonate, filtration, and titration of the excess of alkali, gives satisfactory results. (*Cf.* J.C.S., Dec.)—S. I. L.

Iodimetry; Potassium bichromate as a standard in —— and the determination of chromates by the iodide method. W. C. Vosburgh. J. Amer. Chem. Soc., 1922, **44**, 2120—2130.

Titration of iodine with thiosulphate in dilute acid solutions gives results which are 0·1—0·3% higher and more concordant than the results of titration in a neutral solution. The presence of air affects the titration of iodine with thiosulphate when the acidity of the solution is equivalent to 0·3N hydrochloric acid or greater, causing too much thiosulphate to be required. An apparent excess of oxidising action of bichromate is caused by the titration of the iodine in a solution of too high an acid concentration. This can be corrected by the exclusion of air, but more easily by dilution to such a hydrogen ion concentration that the presence of air will not interfere. Chromates may be determined to within 0·1% by the iodide method under the proper conditions. Potassium bichromate as a standard for thiosulphate solutions agrees with pure iodine to within 0·1%, but gives a slightly lower value. Errors in the iodine standardisation leading to such a difference appear to be about as probable as errors in the bichromate standardisation. A standard solution of permanganate is not trustworthy as a standard for thiosulphate solutions.
—J. F. S.

tandardise a known amount of bichromate in /100 solution, the value found for the latter is bout 4 pts. per 1000 higher than the calculated alue; when the bichromate was 0·003*N* the amount f ferrous sulphate required was about 1% higher han the calculated quantity. The titration of the errous ion with a potassium bichromate solution ives results which agree with those obtained by the everse titration.—J. F. S.

oric acid; Estimation of ——. W. W. Deerns. Chem. Weekblad, 1922, **19**, 480—481.

HE citrate method proposed by Kolthoff (J., 1922, 63 A) for the estimation of boric acid in presence of hosphoric acid is criticised. (*Cf.* J.C.S., Dec.) —S. I. L.

hlorine; Rapid estimation of —— in organic compounds. E. Votocek. Chem. Listy, 1922, **16**, 248—249.

HE author combines the method of Marcusson and Dröscher (J., 1911, 510) with his own method of titrating chlorides with a mercuric salt, using sodium nitroprusside as indicated (*cf.* J., 1918, 444 A). Combustion of the substance in an atmosphere of oxygen in the presence of sodium hydroxide solution is effected in a funnel-shaped vessel of several litres capacity fitted with a stopcock. Since sufficient hydrogen is present in the molecule to convert all the chlorine into hydrogen chloride, the products of combustion are absorbed by water and titrated directly with mercuric nitrate. The estimation takes about 1½ hrs. —W. T.

Chromic oxide; Function of —— in oxidation by means of mixtures of sulphuric and chromic acids. L. J. Simon. Comptes rend., 1922, **175**, 768—770. (*Cf.* J., 1922, 614 A, 646 A.)

IN oxidations by this method it is important that the details as to amounts of reagents to be used should be noted. The organic substance is heated to 100° C. for 4 min. with a mixture of 12—15 c.c. of concentrated sulphuric acid and 4 g. of chromic anhydride; the latter may be replaced by 12 g. of silver chromate. The reagent itself may be similarly heated without loss of oxygen, but, on adding chromium alum, oxygen is evolved, the quantity depending on the amount of alum added. The latter may be replaced by the equivalent quantity of chromic oxide with similar results. In the presence of a sufficient quantity of chromic oxide, chromic anhydride is completely decomposed by sulphuric acid at 100° C.; the quantity added is limited in practice by the fact that the material becomes pasty. The increase in oxidising activity shown in presence of chromic salts may be utilised in oxidising substances such as homologues of acetic acid which are otherwise only partly decomposed. —H. J. E.

Molecular weight of substances in alcoholic solution; Determination of —— from the elevation of the flash-point. R. Wright. Trans. Chem. Soc., 1922, **121**, 2247—2250.

AN apparatus for the determination of the molecular weight of substances in alcoholic solution by elevation of the flash-point consists of a tinned connexion of the silica jet, the rate of [illegible] the bath being about 1° C. in 15 mins. For that determination a fixed constant quantity of liquid is placed in the vessel, which is heated for about 2 mins., the flame removed, and a series of short gusts of air admitted through the spiral by regulation of a clip until constant temperature is reached. The flame is held close to the silica jet while air is being passed through, the heating and aerating being continued alternately until, at the flash-point, the flame strikes back into the vessel with a slight explosion. The products of combustion are swept out by air, the bath cooled 1° C., and the process repeated with smaller temperature intervals between the tests. Of at least four flash-points thus obtained the lowest is taken as the correct value, an accuracy of 0·05° C. being reached. Constancy of temperature before the application of the flash test, sufficient aeration at each application of the flame to the jet, immediate removal of the products of combustion, and dryness of the jet are essential. The flash-point of pure alcohol in this apparatus is 17·4° C., and the flash-point constant 7·7, from which data and the observed flash-points of solutions of known composition the molecular weight can be determined as in the boiling-point method, the results for the substances examined being comparable in accuracy with those obtained by the latter process. The method is, however, tedious, and requires high concentrations of solute, viz., from 2 to 8%.—P. V. M.

Bingham viscosimeter; Drainage error in the ——. W. H. Herschel. J. Opt. Soc. Amer., 1922, **6**, 873—898.

DRAINAGE error in viscosimeters arises owing to the variation with viscosity of the volume of liquid discharged from the bulb of the viscosimeter. Indications of the existence of drainage error in the case of the Bingham viscosimeter are obtained by comparison of results afforded by that instrument with those given by viscosimeters of the Saybolt and Redwood types. Graphs permitting the drainage error in any test may be determined, or indicating a time of flow such that the drainage error is negligible, are given. It is concluded that drainage error in the case of a Bingham viscosimeter having a bulb of volume 4 c.c. is negligible for comparatively light oils only when a sufficiently long time is taken for the discharge, and may be avoided by having the trap on the opposite limb from the bulb which measures the volume discharged. An appendix is devoted to a comparison of viscosities as determined by the Scott viscosimeter and by Basseches's plummet method. In the latter method a cylindrical plummet with a conical base is suspended from one arm of the beam of a balance and is immersed to the junction of the cone and cylinder in the liquid under test. The times taken for the pointer of the balance to traverse a definite number of scale divisions when one or other of two definite weights is placed in turn in the balance pan are determined. The instrument is calibrated by means of a liquid of known viscosity. Results obtained are in fair agreement with one another, but differ considerably from values of viscosity determined by the falling ball method. (*Cf.* J., 1922, 964 A.) —J. S. G. T.

electrolysing the solution. The bismuth and antimony compounds are soluble in alcohol. Copper is separated from the metals of the iron and zinc groups by adding 7 g. of citric acid for each gram of metal precipitable by ammonia present, neutralising with ammonia and adding 5 g. of glacial acetic acid. The solution is made up to 300—400 c.c., heated to the boiling point, and treated with 0·5 g. of phenylthiohydantoic acid dissolved in a little hot water, then dilute ammonia is added until a yellow precipitate commences to form. The solution is boiled, and if the copper is entirely precipitated the precipitate rises to the top and leaves a clea[illegible] and precipitate rises [illegible] (Jamet). tion below, [illegible]ter analysis (Chambard); *Humus soils* ammonia [illegible] *Soils* (Robinson). 991, *Soil moisture* tur[illegible]ighton); *Soil acidity* (Van der Spek); *Iodometric* [illegible]*mination of sugars* (Auerbach and Bodländer). 992, *Inulin* (Castellani and Taylor); *Volatile acids in wines* (M[illegible]). 993, *Tryptophan in proteins* (Lüscher). 995, *Alkalinity of water and culture media* (Noll); *Nicotine in tobacco* (Popp and Contzen); *Alkaloids* (McGill); *Liquorice extract* (Giuffre). 996, *Alanine* (Jaitschnikov); *Urea* (Werner).

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given: they are on sale at 1s. each at the Patent Office, Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, 15 days after the date given.

I.—GENERAL; PLANT; MACHINERY.

Applications.

Caldwell. Production of vapour from distillable liquids or solids. 32,428. Nov. 27.

Cashman. Furnaces. 32,734. Nov. 30.

Gill. 33,341. *See* II.

Goldschmidt A.-G., Lüty, and Schertel. Production of finely-divided solid substances. 33,365. Dec. 6. (Ger., 8.12.21.)

Heller. Production of extracts from organic raw substances. 33,198. Dec. 5. (Switz., 5.12.21.)

Holmes. Pulverising-machine. 33,380. Dec. 7.

Kennedy. Crushers. 32,517. Nov. 28.

Kernohan, Lochhead, and Trink. Furnaces. 33,472. Dec. 7. (U.S., 8.12.21.)

Lewis. Production of catalytic agents. 32,977. Dec. 2.

Lloyd, Meldrums, Ltd., and Simon-Carves, Ltd. Apparatus for effecting intimate contact of gases and liquids. 33,532. Dec. 8.

Lumière. Capillary process for exchange of liquids in chemical processes, dyeing, etc. 33,331. Dec. 6. (Fr., 7.12.21.)

Pickford. Recovery of volatile liquids, solvents, etc. 32,700. Nov. 30.

Russell. 33,252. *See* XVII.

Soc. Gén d'Evaporation Proc. Prache et Bouillon. Apparatus for separating solids from liquids. 33,362 and 33,4[illegible]. Dec. 6 and 7. (Fr., 20.12.21 and 24.1.22.)

Complete Specifications Accepted.

SOCIETY OF CHEMICAL INDUSTRY.

FORTY-FIRST ANNUAL MEETING IN GLASGOW.

The annual meeting held in Glasgow from July 4 to 11, 1922, resembled that held in the same city exactly twelve years previously in that on both occasions a distinguished chemist from North America occupied the presidential chair; Prof. Ira Remsen enjoyed that honour in 1910 and Prof. R. F. Ruttan in 1922. Since the former year, however, the thoughts of home chemists have been widened by an ever-growing recognition of the importance of the Anglo-Saxon condominium, and it is not too much to say that the extremely cordial welcome accorded to Dr. Ruttan was not only an expression of good will and appreciation of his high personal qualities and attainments, but an acknowledgment of the fact that he represents one of the earliest and greatest of the nations constituting the British Commonwealth. The ovation which was given Dr. Ruttan when he was entertained by the London Section at Oddenino's Restaurant on June 26, and which was repeated at the dinner and meeting in the Hotel Cecil on June 28, reached a fitting climax when he took the chair at the Annual General Meeting held in the fine hall of the Institution of Engineers and Shipbuilders on July 4 in Glasgow.

In addition to Dr. Ruttan, Dr. Ellwood Hendrick, of New York, the envoy of the American Section, received a very cordial welcome, and the entire proceedings were graced by the presence of a number of foreign guests, among whom were noted Col. W. R. Lang, of the University of Toronto, Mr. F. E. Cornell, Montreal, Prof. L. F. Goodwin, of Queen's University, Kingston, Mr. A. Lucas, irector of the Government Laboratory, Cairo, Messrs. H. Wigglesworth and J. V. N. Dorr, New York, Mr. A. E. Gibbs, Philadelphia, Mr, H. A. Galt, Ohio, Messrs. W. J. Craig and A. G. Byard, rom Spain, and Mr. J. H. Marshall, from Switzerland. The attendance of home members was thoroughly representative, and the crowded meetings afforded evidence, if such were needed, that the Society has lost none of its popularity and influence among chemists or their half-brothers, the hemical engineers, and among those who walk in heir wake.

Particularly noteworthy features of the meeting were the President's address, the inaugural Messel Memorial Lecture, and the Conference of e Chemical Engineering Group. The numerous ocial functions and other diversions proved xceedingly popular and the whole programme, oth in its conception and execution, reflected e very greatest credit upon the Committee the Glasgow and West of Scotland Section, s chairman, Mr. J. H. Young, technical chemist the Cassel Cyanide Co., Ltd., and its hon. cretary, Dr. J. A. Cranston, lecturer in ysical chemistry in the Royal Technical ollege, Glasgow. It is difficult to bestow too uch praise upon all those who were responsible r or who helped in the organisation of the meet- g, but to each and all the President and Council, eaking in the name of the entire membership, ish to convey their very great appreciation and ncere thanks, and to assure them that "Glasgow, 22" will long remain in their memories as one the very best meetings that the Society has er held. In this connexion especial mention must made of the generous hospitality, which was offered with true Scottish geniality to members and guests, including the ladies, by the Rt. Hon. the Lord Provost of Glasgow, Mr. Thomas Paxton, LL.D., who in several speeches showed that he fully appreciated the value and potentialities of chemical science and industry; the Corporation of Glasgow; the Governors and Staff of the Royal Technical College; the directors of Nobel Industries, Ltd.; the Clyde Navigation Trustees; the Council of the Institution of Engineers and Shipbuilders, for the use of its fine building; David Perry, Esq., a former Lord Provost; the directors of Provincial Cinematograph Theatres, Ltd.; and a number of private individuals whose generosity contributed materially to the great success of the meeting. Nor must we forget to mention the very useful Handbook, edited by Dr. Cranston for the Local Executive Committee, which contained not only the detailed programme and all the necessary information concerning the city and neighbourhood, but a valuable account of the chemical and allied industries of Glasgow and the West of Scotland from the pen of Mr. W. H. Coleman.

Annual General Meeting.

As the full report of the proceedings of the annual general meeting appears, by traditional right, in the Transactions (this issue pp. 209—219), a short summary will suffice in this place.

The civic welcome extended by the Lord Provost and the President's reply were models of terse and apt expression; the Report of the Council was taken as read and adopted unanimously on the motion of Mr. Young, seconded by Mr. Grant Hooper; and the Hon. Treasurer's report, which disclosed a very favourable financial position but a prospect of diminished revenue, owing to the prolonged industrial depression, was also well received. The congratulations to Mr. E. V. Evans were voiced by Dr. S. Miall and Mr. F. H. Carr. The nominations of the Council for the election of president and vice-presidents were approved unanimously, and the ballot for the election of members of Council resulted in the filling of the four vacancies by Mr. J. H. Young, Dr. A. Holt, of Liverpool, Mr. W. A. Williams, of Edinburgh, and Prof. W. R. Hodgkinson, of London.

Presidential Address.

Dr. Ruttan prefaced his address with an expression of thanks for the honour conferred upon the Canadian Sections by his election to the presidency, and laid stress on the good results which had followed the holding of last year's annual meeting in Canada. After a short reference to the international organisation of science, he approached the main topic of his address, the organisation and development of scientific and industrial research. Beginning with the establishment of the parent nation's Advisory Council in 1915, he traced the various movements which had developed in Australia, South Africa, New Zealand, India, and Canada. The remainder of the address was devoted to a discussion of the fundamental problems connected with this branch of national activity, such as the nature and permanency of State-aid, the functions of central institutions, and the respective spheres of action of research associations and universities. In Dr. Ruttan's view, research in both pure and applied science should become one of the accepted responsibilities of the State, and the necessary financial support should be given with the same degree of certainty, permanency, and freedom from politics that is accorded other enterprises of a vital national character. On the motion of Dr. E. F. Armstrong, president-elect, a very hearty vote of thanks was accorded to Dr. Ruttan for his valuable address (*cf.* pp. 211—218 T of this issue), which will undoubtedly be widely read by all interested in this important subject.

After the meeting luncheon was served to over 300 members and guests in the Grosvenor Restaurant by invitation of the Glasgow Section. Mr. J. H. Young presided and made an excellent speech of welcome, to which Dr. Ruttan replied. Similar but more informal luncheons were held on the two following days, at one of which Sir David Macalister, Principal of Glasgow University, was the chief speaker.

In the afternoon of the first day members and guests attended a garden party at The Knowe, Pollokshields, by invitation of David Perry, Esq., the attractions including a band, Highland dances, bagpipes and other purely Scottish delights. The same evening the Lord Provost and magistrates of Glasgow entertained the Society at a reception in the palatial Municipal Buildings. After introductory speeches by the Lord Provost, Dr. Ruttan and Mr. J. H. Young, the guests separated, according to age and inclination, into two groups, one engaging in the dances in the Banqueting Hall and the other listening to a concert of really excellent vocal music, given by the Glasgow Select Choir, and conducted by Mr. Herbert G. Cross.

MESSEL MEMORIAL LECTURE.

On the morning of July 5, Prof. Henry E. Armstrong delivered the inaugural lecture devoted to the memory of the late Dr. Rudolph Messel. The President, having explained the nature of the bequest to the Society, presented to the lecturer the memorial medal, which has been designed by the well-known artist, Mr. E. Gillick. Sir William Pope referred to Dr. Messel as a pioneer in technical chemistry, and to Prof. Armstrong as a pioneer in technical education who had done probably more than any other to improve the quality of science teaching in this country.

The lecture, entitled "Rhapsodies culled from the Thionic Epos, including a discussion of the conditions determinative of Chemical Interchange," proved of absorbing interest; it covered, directly and incidentally, a wide range of topics, and was composed in that incisive, perspicuous and literary style of which the author is a master. Iconoclastic and constructive, retrospective and prospective, satirical and appreciative, the lecturer carried his large audience with him and well achieved the *aliquid certi* he had in view, namely, to lay a foundation and set an example. To equal a predecessor, it has been said, one must have twice his worth; succeeding Messel lecturers will need far more. As the lecture is long and will shortly be printed in the *Transactions*, it is not proposed to desecrate it by presenting it here in abstract form; it must suffice to state that it consisted mainly of a record of the life, work and character of the Society's generous benefactor and the lecturer's intimate friend, and critical but constructive dissertations on chemical action, catalysis, and sulphuric acid. That those who were not present may glean some crumbs which fell from the rostrum, we append a few of the shorter "rhapsodies" as samples of the rest, and assure them that had they heard the applause with which the vote of thanks, proposed by Prof. G. G. Henderson, was received, they would share with the writer the view that only one opinion was possible concerning the success of the First Messel Memorial Lecture.

Messel was the first to give platinum full industrial use; this was his great achievement. . . . A man of astounding vigour and full of feeling, he burnt the candle at both ends and all over its surface.

Platinum may well become the bond of union between the sexes. . . . Gold has led woman to minister to man in the past; why not platinum in the future, especially as our gold is now reduced to paper which cannot be worn with effect as jewellery?

To save the world from a Russian fate, science must be made as constructively effective in commanding human nature as it has been hitherto in hurrying the nations to their ultimate destruction.

The chemist alone, through his thionic influence, has made the Northcliffe press possible, the destruction of forests certain.

The pages of our chemical journals are full of careless writing—of careless writing due to careless thinking.

Everything seems to be now a sort-of-a-kind-of what it used to be; canned goods have captured the world and impudent advertisement counteracts conscience.

We must never forget that the laboratory worker is an artist and that, as a rule, practice comes first; so-called theory is usually brought to the aid of practice, in justification of its acts.

All single things dealt with by the chemist are chemicals. A chemical can only be defined as a material which can take part in a chemical change; combustion undeniably involves chemical change; oxygen is a chemical. Who manufactured oxygen? We can only say—It is!

Don't let us think of Lavoisier merely as a man who heated mercury in air and lost his head; think of him as the pioneer who not only sought to put system into the souls of chemists but also tipped their tongues with harmony.

Every text-book lies in telling the student that hydrogen and oxygen interact to form water.

There is nothing dogmatic in the assertion that all chemical change is an electrochemical, *i.e.*, an electrolytic, process.

Altars have been set up everywhere for the worship of a narrow doctrine mislabelled Physical Chemistry; the chief ikon has been St. Arrhenius, a divinity of Scandinavian origin; Teutonic priests, the Ostwalds . . .

A horrible pedantic jargon has been piled up around ethylic aceto-acetate and other compounds which can lead a double life, beginning with the word "tautomerism": an unnecessary invention.

Hydrogen-ion-concentration is pure gibberish, a chord that cannot be struck upon "the lyre of language clear."

Following the lecture, Mr. W. J. U. Woolcock took the chair and Dr. J. W. McDavid read a paper on "A Rapid and Accurate Method for the Calibration of Storage Tanks." The principle of the method is that water flowing through a tube or orifice under a constant head gives a constant rate of flow. By calibrating the instrument with a particular nozzle, the rate of flow can be determined accurately, so that by observing the time taken to fill a tank to a given level, the volume up to that level can be readily calculated. The apparatus weighs only 26 lb.

Dr. R. A. Joyner followed with a paper on "The Viscosity of Cellulose in Cuprammonium

Hydroxide." The author, using a modification of the method devised by Gibson, Spencer, and M'Call (J.C.S., 1920, 117, 484) has found that the viscosity of the cellulose solution diminishes as the copper content increases up to a certain limit, the concentration of the cellulose and ammonia being kept constant; that the viscosity falls as the concentration of ammonia increases, when the concentration of the cellulose and copper remain constant; but that the viscosity rises as the concentration of cellulose increases, the concentration of copper and ammonia being kept constant. The action of sodium hydroxide on the viscosity of cellulose was studied at different temperatures with varying concentrations, and on the assumption of the presence of two celluloses of widely different viscosity, the reaction appeared to obey the monomolecular law. No degradation products of cellulose were formed when the viscosity was lowered by the addition of N/30 and N/100 sodium chloride solutions at 100° C. A simple relationship was found for the action of air on cellulose dissolved in cuprammonium hydroxide; and the viscosity of the solution was reduced very quickly and without formation of oxycellulose by adding sodium hypochlorite in alkaline solution.

After lunch, members were privileged either to inspect the Dalmarnock Power Station, which supplied last year 151,688,636 B.O.T. units to private consumers, or the Provan Chemical Works, which is one of four plants owned by the Glasgow Corporation for working up by-products of gas manufacture. The Provan Works is the largest and has been completely reorganised during the last two years under the direction of Mr. W. A. Walmsley, with the result that the City is now reaping a handsome profit from the distillation of tar and ammonia. A description of the works is given in Mr. Walmsley's paper read before the Chemical Engineering Group (*cf. i.*).

ANNUAL DINNER.

The annual dinner was held in the Grosvenor Restaurant on July 5, Dr. Ruttan presiding over a very large company, which filled the large dining hall to its capacity. Among the guests were the Rt. Hon. the Lord Provost and Mrs. Paxton, Sir John Reid, Sir John S. Samuel, Dr. Ellwood Hendrick, and Dr. H. F. Stockdale.

After the loyal toasts had been honoured, Dr. E. F. Armstrong, in proposing "The Society," said it had been stated in the Press, and particularly in *The Times*, that we had no technical ability in this country. In rising to propose the toast of the Society of Chemical Industry, he felt bound to refute with all the energy at his command the suggestion that we have not in this country technical ability and aptitude both to invent and to carry out commercial operations. He declared that we have in Great Britain aptitude and ability to carry out any process under the sun; that we do not want to import, introduce, smuggle or convey under any Act of Parliament, under any definition, with or without duty, any kind of foreign chemist, foreign idea or foreign brains into this country. The trouble of chemists was that they did not advertise themselves, and if they would only adopt some of the usual methods of advertisement things would be very much better. The thing that had struck him in Glasgow was the very fine building belonging to the Institution of Engineers and Shipbuilders, and he hoped they would all leave Glasgow with a vow that they would leave no stone unturned until the chemical societies of this country had such a building. He coupled with the toast the name of their President, Dr. Ruttan, whose virtues had been sounded sufficiently already.

Dr. Ruttan, responding to the toast, spoke of the manner in which the Council had carried on the work during the year while he had been in Canada, and especially thanked Sir William Pope, who had acted as Chairman of Council during that period. The affairs of the Society were in a very flourishing condition, as were those of the five sections in Canada, where a General Council had been formed to keep these Sections in closer touch with each other. The result of the work of that General Council was that a meeting had recently been held in Ottawa at which some 100 members from all parts of Canada had attended. It was very important in the interests of the parent Society that this should be done. He read a letter of greeting from this General Council sent from this first meeting, and added that the relationship between the Sections in Canada and the parent Society were very much those of the Overseas Dominions to the Mother Country, bound by bonds of affection but without a constitution, which made them loyal supporters of the parent Society in the one case and the Mother Country in the other. He expressed his complete agreement with what Dr. Armstrong had said regarding advertisement and bringing the claims of chemistry more prominently before the notice of the public, as only in that way would they be able to influence the legislature by bringing forward a strong body of public opinion. Time would not permit him to discuss many matters he would like to, but there was one point he would bring up. The suggestion he wished to make before leaving the chair was that renewed efforts should be made to emancipate the chemists of the universities of the Empire from the domination of German reference books. This had every prospect of success at the previous meeting of the International Union of Pure and Applied Chemistry, but for some reason we in the Empire had not taken a very active part in that very important undertaking. The question had been asked, especially in America, Why duplicate these books of reference? The German books, although leaving much to be desired, were cheap and readily available. There were several reasons for this course of action. The domination by Germany of the reference shelves in the scientific libraries of the world had been an important factor in attracting graduate students to German universities and thus inoculating to a certain extent the universities of the Empire with the German method. Many examples had been quoted, especially in chemistry, where the characteristic chauvinism of the German editors had been so strong as not only to lessen their appreciation of the work of other nations, but also their accuracy in recording achievements of the "Ausländer." That we should be in possession of English summaries of the chemical literature of the last seven years at the earliest possible date was a matter of which the importance was fully appreciated, and no more opportune time to break with the tradition of viewing chemistry "through German eyes" was likely to arise. The longer we waited the more difficult would be the task. Even if the German compendia were impartial there would still remain the objection that, to younger chemists, at any rate, the habit of consulting German works of reference—in default of others—leads by mass suggestion to an appreciation of German effort in chemistry which was by no means warranted by the facts. Moreover, the German compendia were not impartial. The almost exclusive use of German compendia and monographs throughout the whole civilised world had given that country a world-wide influence and prestige out of all proportion to the value of its contributions to knowledge. He hoped that in future students in the Overseas Dominions and the Mother Country would be encouraged to complete their studies in one or the other, and that the courses might be sufficiently attractive to draw students from England to complete their studies at the universities in the colonies. It must be known throughout the Empire that British chemistry was better than German chemistry. It must be known throughout the Empire that there were greater opportunities for gaining knowledge of chemistry in England than there were in Germany. That being the case, he felt sure that it would be possible to establish within the Empire reciprocity between the various universities which would enable us to maintain the prestige of English chemistry and to increase very largely the number of men who were advancing in the higher branches of the science.

Sir William Pope, proposing "The City of Glasgow," spoke of the splendid hospitality which the Society had received at the hands of the Corporation and of all those connected with the meeting in Glasgow.

The Lord Provost, replying, said the Corporation of Glasgow was always willing to welcome societies such as this whose work so closely affected the health of large cities; none more so than the work of chemists. Glasgow had a very dense population, and they wanted all the assistance they could get from the chemical societies and scientific research men to help them in their endeavour to make the city more healthy.

Mr. W. J. U. Woolcock proposed "The Honorary Secretary of the Glasgow Section," and referred to the smooth manner in which all the arrangements for the meeting had worked.

Dr. J. A. Cranston acknowledged the toast and said that everybody connected with the task had done their share and that without that help the work could not have been done.

Mr. E. V. Evans proposed "The Glasgow Section." Mr. J. H. Young, responding, said that the members of the Section in Glasgow felt that they would like to see a definite step forward as the result of this meeting. They could not expect to add many new members at the present time owing to the trade depression, but a great deal of good would be done if joint meetings with the sections of other societies could be arranged. For instance, the Glasgow Section of the Society of Chemical Industry might arrange to hold joint meetings with the Institute of Chemistry; and the same applied to Edinburgh, and the meetings might be held alternately in Glasgow and Edinburgh. This idea of joint meetings might be pushed a great deal further than it had been hitherto and should be applied to such places as Liverpool and Manchester, and elsewhere in the case of towns in close proximity. The plan might be adopted in South Wales also, and in that way much good work remained to be done.

Prof. G. G. Henderson, who proposed the toast of "The Visitors," coupled with it the name of Dr. Ellwood Hendrick, and also suggested that telegrams of greeting should be sent from the meeting to the chemists of Canada and the United States.

Dr. Elwood Hendrick, in reply said:—

From across the deep waters I bring you greetings and the assurance of all good will and fraternity. I shall ask you to take this statement for granted and the message as delivered, because in addition to the felicitations of ceremony and the message from our hearts, I bring also a problem and seek its solution.

In what follows I shall speak only of conditions in the United States. Whether these obtain in similar or in less measure here or elsewhere in British possessions you will know far better than I. The problem has to do with the great gulf that lies between the profession of chemistry and its business. As corporations grow in magnitude, this gulf threatens to become even wider; and since Mr. Young touched upon the subject yesterday I venture the belief that you are not total strangers to it.

We study long and ardently to attain proficiency in science and in its practice. On the other hand, no study, no proficiency, no competency, and sometimes not even character, is demanded of him who would engage in the business of chemistry. So long as he can offer or borrow money he is welcome. This is because the need of chemical development is so urgent for the welfare of every industrial nation that we do not dare place hindrances in the way of it. The situation follows, however, that the business rules the profession; rules it in its own field. This is not true of all chemical enterprises by any means, but it occurs so frequently that gross ignorance directs chemical practice, that I venture to make this general statement: in the United States the weakness of chemical industry is not in the works, or in equipment, or in labour, or in engineering skill, or in the chemists themselves; it rests in the boards of directors of chemical establishments.

Corporations have the unfortunate habit of what we call window-dressing, in which men who have achieved success in any walk of life are thought to assure it also in chemical industry. Thus, a successful banker, stockbroker, lumber merchant, mine owner, and what-not are invited to join the board in the belief that the public will follow the mistaken idea that astuteness will conquer in spite of ignorance.

In no other great profession than ours does this situation exist. Imagine if you will a sick man sending for a physician and demanding that he punch a time clock coming and going, that he be paid according to the time spent in reaching his diagnosis; and that he prescribe treatment wholly according to the patient's whim and desire; or of a client insisting that his counsellor at law shall construe the law according to his wish and not as it is written.

The control of chemistry by business has reached such a pass that I have known a speculator in the industry to destroy the entire research organisation of a great establishment engaged in the most difficult and involved scientific processes, and to consult an excavation engineer for enlightenment as to how the works should be operated.

The future of the industrial nations rests with their chemists. According as they are more or less men of wisdom and understanding, and above all things men of character, industry will flourish or fade away. We cannot ask for all of these standards from the man who represents the investment of capital alone.

Now the last thing we want to do is to restrict the rights of property, or to destroy initiative. But chemical industry is a professional institution, and it cannot flourish if it is ignorantly directed. Chemical vision and understanding are required of it if it is to prosper. And the looting of corporations by cutting off necessary expenditures for research and technological development, the use of such funds for dividends, or to make a brave showing for the market manipulation of shares, is so great an offence against the general welfare that no self-respecting chemist should countenance it or endure participation in it.

Before anyone is admitted to the practice of medicine, it is required of him that he make a solemn oath to devote himself to human welfare. A solemn oath of allegiance to the principles of right is required of everyone who would practise at law. At present, chemists pass examinations—and look for a job. This does not accord with the great obligations of our profession. Therefore, as a possible means to secure a better status for the profession of chemistry in its own affairs, I venture to suggest that an Oath of Science be drawn and administered to everyone who would engage in chemical practice. He should bind himself on honour to seek diligently the truth by the right co-ordination of all facts, which alone leads to the truth, to abstain from all knavery under any and all conditions, and to address himself to the welfare of humanity, striving throughout his days to seek the light of greater understanding and to bring about a larger, a better, and more abundant life for all mankind.

Two sources of enjoyment were provided for the morning of July 6. A large party accepted the invitation of the Clyde Navigation Trustees and made a tour of Clyde Harbour on board a boat specially placed at its disposal; and the other spent an enjoyable morning in the Picture House, Sauchiehall Street, where, among more frivolous pictures, they saw a film depicting the manufacture of rubber goods, kindly lent by the North British Rubber Co., Ltd., and a second, lent by Messrs. Chance and Hunt, Ltd., showing the mining of sulphur by the Texas Gulf Sulphur Co., U.S.A. A third film, relating to the manufacture of newsprint in Quebec, was unfortunately not available.

CHEMICAL ENGINEERING GROUP.

Among those to whom congratulations are due is the Committee of the Chemical Engineering Group for organising what proved to be the most successful conference which the Group has yet held. The subject discussed was Evaporation and Distillation and under this heading the following papers were read:—(1) "Observations on the Design of Ammoniacal-Liquor Stills," by Mr. P. Parrish; (2) "Tar Distillation," by Mr. W. A. Walmsley; (3) "The General Problem of Evaporation," by Prof. J. W. Hinchley; and (4) "The Historical Development of the Distillation of Glycerin," by Mr. T. H. Gray. Mr. W. H. Coleman presided at the first session and Mr. J. Arthur Reavell, chairman of the Group, at the second. The discussions which followed the reading of the papers were bright and very useful to the technical men concerned; and the attendance throughout was extremely good. Abstracts of the papers are appended:—

Ammoniacal-Liquor Stills.

The present continuous columnar still for the distillation of gas liquor owes its origin to Savalle (1875), who was apparently intimately acquainted with the design and operation of the apparatus invented by A. Coffey in 1831 for producing in one operation a more concentrated spirit from alcoholic mashes. It is estimated that the quantity of gas liquor produced and distilled in the United Kingdom is approximately 1250 million gallons of 1·73 per cent. ammonia per year. The view is expressed that little advance has been made in the design of ammoniacal-liquor stills, largely because designers and manufacturers have concentrated their efforts on a circumscribed phase, viz., facility in removing the elements to admit of cleaning, and have to a large extent ignored, or overlooked, the question of operating costs and thermal efficiency, which are the major considerations.

The arrangements of gas-liquor stills are divided into three categories and the distinctive features of each are described and discussed. It is suggested that solutions of ammonia of such strengths as are typical of normal gas-liquor behave generally according to Henry's law. Gas laws, however, whilst allowing of a ready interpretation of the conditions obtaining in the still, do not afford all the fundamentals necessary to design, and the view is expressed that it is only by patient observation of details, such as can be obtained from practical working conditions, that an advance in the design of the elements constituting gas-liquor stills can be made possible.

Two diagrams dealing with the thermal aspect of gas-liquor stills, as affecting the manufacture of sulphate of ammonia, are furnished, and these give information on a phase of the subject concerning which singularly few data have hitherto been available.

The conditions governing the water balance of a saturator are then dealt with. This subject is of interest owing to the introduction of washing processes for the production of neutral sulphate of ammonia.

Several graphs, plotted from experimental data, are given to show:—(a) Liquor and gas concentrations at two rates of feed with identical steam consumption; (b) efficiency of a gas-liquor still from the standpoint of steam consumption; (c) relationship between the composition of the liquor being distilled and the distillate leaving the still; and (d) intrinsic capacity of a still for dealing with gas liquor of varying concentrations.

The essential parts of a unit of plant for continuous distillation are described, and the following points, among others, are considered:—(a) Gas-liquor storage tanks; (b) preheaters and coolers; (c) Devil-liquor storage tank; (d) constituent parts of gas-liquor stills; (e) liming chambers; and (f) seal pots. Many interesting observations of considerable practical utility are made, including some relating to the starting and working of gas-liquor stills which should appeal to those who are responsible for their control and supervision.

Finally, an indication is given of the direction in which still design and arrangement are likely to advance. It is suggested that the present arrangement of plant does not allow of maximum conservation of the available heat, and that modification in this respect is essential. Designers must concentrate their efforts on the evolution of the elements of a still which admit of optimum bubbling of an attenuated character, together with maximum impact of the respective bubbles so formed. Time contact between liquor and vapour must also be ensured to promote rapid distillation. Optimum bubbling is a function of a definite vapour velocity which differs in each compartment of the still. Instead of the perforations or serrations of the elements being uniform in size, as at present, they must be varied to suit the varying volumes obtaining.

In the ensuing discussion Mr. Cooper expressed the opinion that a saving of more than 15 per cent. in the steam consumption of a still was not possible, and Dr. E. W. Smith discussed the effect of using an ammonia catch in reducing the cost of producing ammonium sulphate. Two forms of hoods were described by Mr. Ramsay Sibbald, who said he had used them to replace the serrated hood, which is sensitive to slope of the column. Professor Goodwin pointed out that depth of liquor on the trays had a certain bearing on the efficiency, and that the presence of oil would greatly influence the ultimate contact between the steam and gas. Mr. Byard urged the use of superheated steam, and described its uses in a Continental works. Mr. Coleman, the chairman, in thanking Mr. Parrish for his paper, observed that this was the first paper in which the application of scientific principles to the design of ammonia-liquor stills had been fully studied. He also described the Mallet type of dissociator. Mr. Parrish gave a detailed reply.

Tar Distillation.

Of the types of tar produced in gas-works' practice, that derived from coal carbonised in horizontal retorts is essentially a high-temperature tar, whilst tar produced in vertical retorts may be regarded as a mixture of low-temperature and high-temperature tars. Low-temperature tars are essentially paraffinoid and high-temperature tars benzenoid in character. The tar acids extracted from the oils obtained by distilling "horizontal" tar are mainly phenols and phenol homologues; those derived from "vertical" tar contain polyhydric phenols showing great affinity for oxygen.

The distillation of tar may be roughly divided into two parts:—(1) The primary or crude distillation, which consists in evaporating from the tar a certain amount of its volatile matter, condensing this volatile matter and separating it into fractions, leaving behind in the still a residue of pitch of good merchantable quality; and (2) refining operations, under which are included all subsequent operations, such as the extraction and refining of tar acids, benzols, naphthas, etc.

The paper describes, with the aid of drawings, the lay-out of the Glasgow Corporation's Provan Chemical Works, and types of plant erected there for distilling tar and refining tar products. These works were designed with a view to obtaining a straight flow line through them, the waste materials travelling to one end and the finished materials to the other. The causticising portion of the carbolic-extraction plant is of interest in that the system is continuous. It comprises two Dorr reaction agitators and two Dorr thickeners, with Harding conical ball-mill, in which the lime is ground and slaked, and an Oliver continuous rotary filter for filtering the waste calcium carbonate sludge. There is also a Scott's evaporator for concentrating the caustic soda. The stripping of naphthas from light oils is carried out in two Wilton oil-topping plants, each of 10,000 gallons capacity per day. Three types of column are described in the paper, viz., the column packed with Lessing rings, the bubbler type of column, and the Kubierschky spraying column.

The paper also describes an experiment on the continuous distillation of vertical-retort tar, carried out in two Wilton dehydration coils, with a final steaming still. The tar in the first coil was maintained at 170° C. and at a pressure of about 30 lb. per sq. in. On releasing to atmospheric pressure, naphthas and water passed off as vapours to the condenser, and the residual tar was then pumped through the second coil, where the temperature and pressure were maintained at 360° C. and 24 lb. per sq. in., respectively. On reducing to atmospheric pressure, mixed carbolic and heavy oils passed away as vapours to the condenser, and the residual tar was steamed with superheated steam in the final superheating still. The experiments showed that tar could be distilled continuously with production of a good medium soft pitch of 120° F. twistpoint, even without the final steaming-still.

In the ordinary method of distillation, the tar yielded approximately 57 per cent. of oils and 43 per cent. of pitch. Under the conditions of the experiment, the yields were 73 per cent. of oils and 27 per cent. of pitch. The increased quantity of oils and the reduced quantity of pitch show that considerable cracking had taken place. The experiment, however, is not complete, as the oils produced have not yet been fully investigated.

Questions were asked by Messrs. Nichols and Mavis regarding details in connexion with the works, and in the discussion which followed Mr. Maclaurin made a strong plea for the adoption of a better nomenclature of high- and low-temperature tars, suggesting that these should be divided into five grades, namely, high-temperature tars, semi-high-temperature tars, medium-temperature tars, semi-low-temperature tars, and low-temperature tars. Mr. Parrish believed the time of contact between the flue gases and the stills in the new plant was too short and advocated the spiral instead of the vertical form of flues. He also expressed a wish that Mr. Walmsley would carry out tests on the different types of columns which had been installed at the works. The Wilton still was discussed by Messrs. Cooper and Potter, the last-named speaker giving a series of interesting figures illustrating the running of this type of plant. Mr. Coleman mentioned a series of experiments which he had carried out on pre-heaters, and suggested that a study of chimney losses would assist in economising in fuel.

The General Problem of Evaporation.

Evaporation in the technical sense is synonymous with vaporisation, which may take place under two distinct conditions, viz., at or below the boiling-point of the liquid evaporated. The study of the latter condition has occupied the attention of physicists, meteorologists, physiologists and others to an extraordinary extent for many years, but rarely has the work had any chemical-engineering aspect. Fifty years ago Stephan concluded that the rate of evaporation was proportional to the linear dimensions of the surface, and assumed that in still air it was strictly proportional to the difference between the vapour pressure of the liquid and the vapour pressure in the air; these conclusions, however, are of little use to the chemical engineer.

From a large number of experiments performed under laboratory and factory conditions, the rate of evaporation from a water surface is given by the formula

$$W = 26{\cdot}2\left(1 + \frac{v}{1{\cdot}17}\right)\left(\frac{p_e - p_a}{P}\right)^{1{\cdot}2}$$

where W is the weight of water evaporated in kg. per sq. metre per hour; v is the velocity of the current of air in metres per second; p^e is the vapour pressure of the liquid in mm. of mercury; p^1 is the vapour pressure of the water vapour in air in the same units; and P is the barometric pressure. It is obvious that the formula should give satisfactory results with any solution, if the depression of the vapour pressure of the solution due to the presence of the salt be taken into account. As from a theoretical point of view the rate of evaporation in a still atmosphere should be proportional to the vapour-pressure differences, some explanation of the index is desirable. The explanation seems to be that absolutely still air is impossible under the conditions, for moist air is lighter than dry air, so that convection must be a normal accompaniment of evaporation. Again, when there is a difference of temperature between the liquid and the atmosphere, the convection effect is still more marked.

The above formula may be applied to drying operations as well as to evaporation from crystallising tanks and similar plant. Evaporation at the boiling-point brings forward a completely different set of conditions.

The rate of heat transmission in evaporating plant depends on the temperature drop and the temperature level; the velocities of the liquid and steam over the heating surfaces; the viscosity and density of the liquid; the resistance of the heating surfaces and any deposited scale; and the resistivity of the material of which the heating surfaces are made. There is little doubt that the rate of heat transmission is nearly proportional to the temperature-drop, but since mechanical disturbance takes place in some relation to temperature-drop and temperature-level and is limited by the design of the plant, no mathematical equation can be deduced except for a particular design. For any particular type of plant or at any particular temperature-level there is one temperature-drop at which the heat transmission will be a maximum.

All manufacturers know the value of "circulation" and the problem is approached by them in several ways. Mechanical circulation has been adopted with highly beneficial results; it is always found that an improvement in heat transmission results, if the circulation be improved by increasing the area of "down-comers," by altering the hydrostatic head, or by other means.

The presence of solid matter in the liquid to be evaporated is often beneficial in limiting the amount of scale-formation, but in nearly all cases the problem of scale-formation is a problem for the chemist as well as for the chemical engineer.

It will be realised that owing to the high latent heat of steam the cost of evaporating water is very high unless steps be taken to recover the heat dissipated in the steam. By using this steam in a second apparatus working at a lower temperature and pressure, and so on, one obtains the well-known system of "multiple evaporation."

Another method of recovering the latent heat of the evaporated steam has been brought to some practical success recently. By compressing the evaporated steam its temperature may be raised so that it can be used again as heating steam in the evaporator. This is equivalent to making the heating surface of the apparatus the condenser for the evaporated steam. Siemens tried this plan in 1868, but on account of the low efficiency of compressors in his day the experiment was a failure. A "heat pump" enables one to obtain by a single evaporating apparatus the same efficiency as is obtained with a triple- or quadruple-effect evaporator.

All those who contributed to the discussion, viz., Prof. Goodwin and Messrs. Parrish, Pooley, Malpass, and Alliott, considered that the paper offered considerable food for thought. The question of frothing was raised and several interesting suggestions were made regarding its prevention and elimination. Several speakers were of the opinion that the heat pump had to be viewed from a commercial as well as a scientific standpoint, and that it was not a sound economical proposition.

History of Glycerin Distillation.

Starting with a reference to Scheele's "sweet principle of fats" (1779), obtained by digesting lead oxide with olive oil, the author alluded briefly to Cap's process (1830—40), and also to that of Tilghmann (1850), who passed an emulsion of fat and steam through iron or copper pipes at 600° F. G. F. Wilson, of Price's Candle Co., made the first notable advance, in 1854, by actually distilling candle-works' "sweet liquor," using pre-heated copper stills of 10—30 cwt. capacity and air condensers. Although this process was economically wasteful, owing to the high temperature used, it persisted until the introduction of modern steam-heated vacuum stills.

After referring briefly to the patents of G. F. Wilson (1854), Wilson and Payne (1855) and E. T. Hughes (1859), the author described the process of F. J. O'Farrell (1881) as the next important advance. This inventor patented the use of vacuum and pump for distilling crude soap-lye in steam at 200° C. The extension of the use of glycerin for blasting and in the arts led to considerable activity in the design of apparatus and patents were issued to Clark (1881), G. Payne (1882), O'Farrell (1883), A. M. Clark (1884), and A. G. Brookes (1885); but the next notable advance was made by the Belgian Van Ruymbeke (1893), who patented the master idea of using a high-pressure steam coil for heating the still, thus dispensing completely with direct fire heat. This, together with the use of expanded re-heated steam for the actual distillation, obviated to a great extent the decomposition of the glycerin.

Scott's patent (No. 15,159 of 1899) constituted the next step forward, and the author described in detail a modification of the original plant which he had used, together with some results obtained in large-scale working. The plant patented by W. E. Garrigues in 1905 (No. 24,100) was next described and characterised as somewhat complicated, but economical in consumption of heat energy. Even more intricate and more economical was the plant of F. J. Wood, of which the main idea was to work from one to six stills with one jet of steam (E.P. No. 21,658 of 1907, and No. 24,920 of 1913).

The latest development in glycerin-distillation is contained in the patent of the Société Française des Glycerines (No. 125,574 of 1919). The plant is designed to work without the use of free steam. Crude glycerin at 180° C. is passed in an atomised state by means of suitable jets from one vessel to another vessel or still of higher vacuum. Steam coils maintain the temperature at about 180° C., and condensers and pump are used as required.

During the discussion, in which Prof. J. W. Hinchley and Messrs. Pooley, Parrish, and Hayhurst took part, several important points, such as purity of yield, entrainment of impurities, points where losses occur, use of oil as heating medium, etc., were raised. In replying Mr. Gray stated that as his records had been destroyed by fire, it was impossible to give actual figures.

Conversazione at the Royal Technical College.

The social functions of the annual meeting were fittingly terminated on Friday evening, July 7, by a conversazione held in the Royal Technical College by invitation of the Glasgow Section. Prof. Thomas Gray briefly welcomed the guests in the Hall, and in speaking of the prominent share taken by the Section in the doings of the Society reminded them that two former Presidents, Sir George Beilby and Prof. G. G. Henderson, were members of that Section. Notwithstanding the attractions of the dance, which commenced forthwith, a large proportion of the visitors made the tour of the building under the guidance of Student-Associates. There were two parties—one proceeded upwards to the fourth floor to attend the first experimental chemistry lecture and inspect the chemical laboratories, and then to descend to other parts of the building, whilst the other visited the mechanical engineering laboratory in the basement to witness machinery in motion, and then worked upwards so as to arrive at the fourth floor in time for the second experimental lecture.

There were exhibits in the following Departments: — Mechanical Engineering, Electrical Engineering, Library, Natural Philosophy, Pharmacy and Materia Medica, Botany and Bacteriology, Mining, Architecture and Building Construction, Metallurgy, Geology, Textile Manufacture, Chemistry and Technical Chemistry. The latter part of the evening was devoted to dancing and social intercourse.

Excursions.

No visit to Glasgow would be complete without a trip to the historic Loch Lomond, and so on Friday, July 7, a special train conveyed a very large party of members and ladies to Balloch, where they embarked on a steamer which took them to the head of Loch Lomond and back to Tarbet. Lunch and tea were served on board, and a stay was made at Tarbet to give the party an opportunity to walk over to Loch Long.

The Saturday was spent by 100 fortunate members at the Ardeer Works of Nobel Industries, Ltd.; the special train left Glasgow at 9 a.m. and returned at 5 p.m. The visit was both enjoyable and instructive, and we hope to give an adequate account of it in a future issue.

On Monday, July 10, there was an excursion to the Trossachs. The party went by train to Aberfoyle, and thence by coach to the Trossachs Hotel, where lunch was served. A walk of about one mile brought the party to Loch Katrine pier, where members embarked for Stronachlacher. At this place coaches were taken to Inversnaid on Loch Lomond, and the return journey was made by boat to Balloch, and by special train to Glasgow. The last day was spent in Edinburgh, where the Castle, the "Royal Mile" and other historic places were visited in the forenoon. Lunch was taken in the Caledonian Station Hotel, and in the afternoon the new chemical laboratories of the University were inspected by kind permission of Sir James Walker, and a visit was made to the Forth Bridge.

THE TRAINING OF THE CHEMICAL ENGINEER.

On June 28, Dr. R. F. Ruttan was welcomed to this country at a dinner given by the Committees of the Chemical Engineering Group and the Chemical Industry Club in the Prince's Room of the Hotel Cecil, London, and subsequently a meeting of the two organisations was held to hear his address on the training of the chemical engineer. Mr. J. Arthur Reavell presided over a very large attendance. As Dr. Ruttan's address will be printed in a later issue of this *Journal* it will suffice in this place merely to indicate the nature of its contents.

In a country like Canada, where ultimate success depended entirely upon the utilisation of vast natural resources, the type of man in greatest request was he who could adapt to prevailing conditions methods, principles and processes already known and well-tried elsewhere; such a man was the chemical engineer and one of the pressing problems was to provide an adequate supply of chemical engineers to meet both the present and the future demand. The chemist and the engineer had been called respectively the physician and the surgeon of industry, each playing his allotted task in promoting industrial science, but the claims of the general practitioner must not be overlooked; the chemical engineer must be able both to diagnose with the deftness of the physician and remedy with the assurance of the surgeon.

Attempts made in certain American and British universities to train the chemical engineer by providing the student with plant and demonstrating to him processes on a semi-large scale had not been successful, and in his opinion the best means was that initiated at the Massachusetts Institute of Technology, which consisted, briefly, in a 4-years' thorough grounding in the fundamental sciences, supplemented by a year's practical training in one or more specially selected and equipped stations. Such stations were situated near to large industrial centres and were provided with plant covering a wide field of technical operations; and each unit was directed by a fully qualified lecturer experienced in works' practice and provided with a technical library, together with a wealth of information available in the form of experience gained by specialists in working the various plants engaged in the industry.

Dr. E. F. Armstrong said that the scheme outlined by Dr. Ruttan was extremely interesting, but he had been taught from boyhood to doubt everything until he was convinced, and then to remain sceptical. The great difficulty lay in teaching the student two great subjects—chemistry and engineering—concurrently. Five years' training would be insufficient to produce a man who would be fit to enter a works. The type of man most wanted in chemical industry was one who, above all else, had a good knowledge of chemistry, whose knowledge was absolutely up-to-date, and who knew how to search the latest literature for matter he did not know. Provided the aspirant had been well grounded in chemistry and physics, those in the factory could teach him all that was necessary to make him an efficient works' chemist, particularly if he had a mechanical turn of mind.

Prof. F. G. Donnan said that the most important *desideratum* in chemical engineering was complete mastery over the all-important subject of physics. Industrial chemistry was almost entirely physics. As a professor he was inclined to agree with Dr. Armstrong that the universities were unable to turn out fully-qualified chemical engineers. It was impossible to erect full-sized plant in our universities, and useless to demonstrate with miniature plant.

Sir Robert Robertson thought that the American plan would be successful. At the beginning of the war there was a great dearth of men able to work and design plant, and although few were called upon to design, experience had shown how rapidly those who were well-trained in pure physics and chemistry were able to take control. One defect in the scheme was the omission of training in costing. Dr. Ellwood Hendrick expressed the opinion that the most important factor leading to success in chemical engineering was the possession of inborn curiosity and personal inclination, and he described how at the Pratt Institute, Brooklyn, U.S.A., under Dr. Allen Rogers, ordinary industrial workers had been successfully trained on lines which took advantage of those innate qualities to convert them into competent works' chemists. He hoped and anticipated that applied psychology would be called in to aid in the selection of the right type of man. Mr. J. McKillop suggested that no scheme of education was complete unless it included training that would qualify the chemical engineer to occupy the highest position in the works, viz., that of managing director; and after Dr. Schack-Sommer had given his views, Dr. Ruttan expressed agreement with Prof. Donnan's opinion that physics should be studied far more than it had been in the past; organic chemistry should be made more quantitative, and some of the time now devoted to making preparations should be given to the study of theoretical chemistry, and especially physical chemistry, a sound knowledge of which was of supreme importance to the chemical engineer.

THE CHEMICAL INDUSTRY CLUB.

A few weeks ago a meeting was held at the Chemical Industry Club which may have important results.

The Club has been established in its present premises for nearly three years and has grown steadily, not only in numbers, but also in its position relative to the general development of the profession and industry of chemistry in this country. The strong desire for greater unity among the manifold interests of chemistry, which has shown itself in so many ways since the commencement of the war, is as keen as ever, notwithstanding the difficult period through which all have been passing. This desirable end is not easy to attain. In addition to the social side, there are other, and perhaps more important, sides upon which it is desired to bring chemists and those interested in chemistry more closely into touch, and whilst this is recognised, it is being more and more strongly felt that the Chemical Industry Club can provide at any rate a common meeting place where the other questions can be freely discussed and from which, perhaps, they can be developed. It has naturally taken time for this feeling to grow, but that it has grown is now generally recognised.

Some time ago the Federal Council for Pure and Applied Chemistry recognised the Club as an important factor in the general organisation of chemistry by inviting one of its number to represent it officially upon the Council. It is well-known that the Federal Council represents all the different chemical interests, and is the only body of its kind in the country. Its object is unification of purpose and development. At one of its recent meetings it approved by resolution the general idea of developing the Club in the interests of the profession and, at the invitation of the Club, appointed seven of its members to attend a meeting with seven representatives of the Club to discuss the best means of extending its usefulness. It is this meeting which is referred to above.

The seven members of the Federal Council who were appointed were Sir William Pope, the chairman, Prof. H. E. Armstrong, Dr. F. E. Armstrong, Dr. Stephen Miall, Mr. W. J. U. Woolcock, Mr. E. V. Evans, and Prof. J. S. Phillip. The members of the Club, who were appointed by the Executive Committee, were Mr. A. G. Craig, the chairman, Dr. W. R. Ormandy, Dr. F. B. Dehn, Dr. A. Rule, Mr. T. Miller-Jones, Mr. W. Cullen, and Mr. H. E. Coley. These fourteen gentlemen, with the single exception of Mr. Woolcock, who was unfortunately prevented from being present by a previous appointment, dined together at the Club and after dinner discussed the subject in detail.

It is inadvisable to enter into the details of that discussion, which was very frank, for to do so would be to depart from the recognised principle laid down for all Club meetings, viz., not to give publicity to the views expressed. The Club has always endeavoured to promote frank expression of opinion, which is essential to its success. Consequently, what was said at this very interesting gathering, and a good deal was said, will be regarded merely as a necessary but confidential preliminary to the results obtained.

However, some facts and figures were given in order to enable those present to form their opinions, and these are of general interest. It was stated that the number of members standing on the books of the Club at that moment was 727. Of these 456 were town members, 244 country members, and 27 foreign members. Although such a membership was regarded as indicating very great progress, it was felt that there were many more who might and should join, and that the total did not represent all the support the profession and industry generally could give to the Club. It is, perhaps, understandable that in the early days of the Club some should have doubted its usefulness and were therefore not disposed to support it, but that feeling is practically eliminated, and now that the Club is receiving support from so many leaders of the profession, there is no reason why it should not increase very materially both its membership and its usefulness.

Financially the Club has been a success. It has paid its way without asking for a single donation or calling upon its guarantors for one penny. It has succeeded in accumulating sufficient funds to enable it to undertake necessary improvements, slowly, it is true, but surely. But it needs a little more support to enable it to provide some facilities which are perhaps not absolutely necessary but are certainly very desirable. At the present rate of subscription, which is very low (£3 3s. for town members, £2 2s. for country members, and £1 1s. for foreign members), each member contributes an average of about £2 14s. to the Club's income. The premises are sufficiently spacious to accommodate 1000 members, and an increase to this figure is one of the immediate objects in view.

Such a gain in membership would increase the income by about £700, and with this sum much could be done to increase the general efficiency of the Club. At the same time it must be remembered that the present facilities are not by any means limited to those seen and enjoyed in the Club premises proper at No. 2, Whitehall Court. The members have the use of another dining room across the corridor, an excellent lounge and drawing room, and bedroom accommodation.

It was made clear at the meeting referred to that the present Club could serve as the nucleus of a much more elaborate and imposing organisation, and so fulfil the dreams of many. But such growth would have to be steady and sure. The ambition was approved, but those who could claim the longest experience and the greatest influence in the profession advised, and rightly advised, a continuation of the steady work which was now proceeding, and promised the weight of their influence in the effort. They thought that if the present policy of keeping the Club as chemically select as possible were continued, an increasing number of professional men would apply for membership.

And so, as the result of a very pleasant evening, it was decided to hold regular meetings of the representatives present, with the object of gradually building up the Club on sound lines in the interest of the profession and industry of chemistry generally. The fourteen members named above have undertaken, with the consent of the two organisations—the Federal Council and the Club—to work individually and collectively to make the Club better known and greatly to increase its influence in uniting the separate chemical interests of the country into a concrete and powerful whole.

STELLAR CHEMISTRY.

H. DINGLE.

The science of chemistry owes its origin and early development to the inspiration of one great idea. With a passion almost religious in its fervour, men consecrated their time, their thought, their energy—their whole lives, in short—to the search for the Philosopher's Stone. Universal transmutation was the goal of their ambition. We do not think much to-day of the Philosopher's Stone. We look upon it as chimerical, unworthy of the serious attention of scientific workers. Transmutation we know takes place; we have direct evidence of it; but the Philosopher's Stone—that is too much for our credulity.

And yet, if we take the trouble to examine the grounds on which we reject it, we shall find our justification not a very easy thing to establish after all. Shall we say the idea is too fantastic, somewhat too reminiscent of the Arabian Nights? It ill becomes us, in these days, to deny existence to the marvellous. Are not the Arabian Nights themselves made to look commonplace? Pioneers of aeronautics have given us a carpet as magical as any conceived by the Eastern mind. Centuries ago a Greek Aladdin rubbed a rod of amber, and the genius of the rod now lights our cities, warms our homes, carries us to the ends of the earth, and executes our enemies. No; it is not on these grounds that we can reject the Philosopher's Stone. Nor can we take refuge in the fundamental diversity of the chemical elements. That doctrine, from which the 19th century drew such nourishment, is barren for the 20th: the atom is no longer the ultimate particle of matter. We are forced, then, to the contention that there is no evidence for the existence of a Philosopher's Stone, that it diverges from the whole trend of modern thought, and that it is therefore intrinsically improbable. But can even this position be maintained? If we consider stellar spectra in relation to temperature, we find that the hotter the star the simpler the spectrum, until at the highest temperature we obtain practically nothing but the lines of hydrogen or helium. Is it, then, not reasonable to argue that in temperature we have the true Philosopher's Stone, converting all things—not, indeed, to gold, but to the infinitely more precious substance, hydrogen? Whatever may be said on this point—and we shall return to it later—there is no doubt that if a modern chemist devoted his attention to the production of extremely high temperatures, with a view to the transmutation of every element into hydrogen, he would be regarded, not as a fanatic, but as one engaged on a problem of the utmost importance and pertinence. It would be strange indeed if chemistry, after abandoning the idea that retarded its progress for so long, were led by the onward march of progress back to that idea again.

Stellar chemistry has, indeed, a wonderful tale to tell. It was in 1859 that the researches of Kirchhoff and Bunsen, on the absorption of light by luminous gases and vapours, showed for the first time how the solar spectrum was to be interpreted. With that discovery a new era was opened in the annals of science, no less fundamental and infinitely farther reaching, both in space and in time, than the simultaneous announcement by Darwin of the doctrine of biological evolution. Everyone now knows how the twin sciences of astrochemistry and astrophysics arose. The spectra of terrestrial sources of light were, broadly speaking, of two kinds, depending on the physical state of the luminous body. A glowing solid or liquid gave rise to a bright continuous spectrum. An incandescent vapour produced a spectrum consisting of bright lines or bands on a dark background. The fact that the latter type of spectrum was characteristic of the chemical nature of its source suggested a means of analysis far more convenient than the standard reaction methods, and one which could be applied to substances at any distance from the experimenter so long as they were in the gaseous form and sent out sufficient light. The stars—and, in particular, the sun—were at temperatures incompatible with any condition but a gaseous one, and it would seem, therefore, that their composition could be determined. But there was a serious difficulty, in that the solar spectrum was of a kind quite unlike that of a luminous body on the earth. It consisted of a continuous spectrum, crossed by a large number of *dark* lines and bands. What was to be made of this? Kirchhoff and Bunsen solved the problem by showing that the dark lines were produced by absorption, and not by emission, of light. They found that if a glowing gas were placed in the path of a beam of light from a hotter source, giving a continuous spectrum, the gas would absorb from the beam just those "wave lengths," or spectrum lines, which by itself it would emit. The resulting spectrum would have a continuous background, crossed by dark lines in positions corresponding to the emission lines of the interposed gas, and would therefore serve the same purpose, so far as chemical analysis was concerned, as the emission spectrum of the gas.

The meaning of the solar spectrum was at once made clear. The sun consisted of a central mass giving a continuous spectrum, and an outer envelope of cooler vapours, whose chemical composition could be ascertained by comparing the dark lines of the solar spectrum with the emission lines of various substances produced terrestrially. It was not long before the spectra of other stars were obtained, and found, in the great majority of cases, to be absorption spectra of similar type, though not always showing the dark lines in the same positions. It appeared, therefore, that the constitution of the sun was typical of that of most of the members of our stellar system. Confirmation of this constitution was obtained by placing the slit of the spectroscope tangentially to the sun, so that only the light of the outer portions was analysed. The spectrum obtained showed bright lines, most of which were identical in position with some of the dark lines in the ordinary solar spectrum.

Thus, almost at a bound, chemistry became a cosmical science. We are accustomed to this today, and it is perhaps a little difficult for us to realise what must have been the emotions of those before whose eyes the larger field was spread for the first time. Dynamics—which for so long had been the sole guide to cosmogony—now shared the honour with chemistry. Indeed, chemistry took precedence, for whereas dynamics was practically confined to the solar system, chemistry could extend its labours into the whole of the visible universe. By far the most striking fact of stellar chemistry is the discovery that the universe throughout consists of practically the same elements as those with which we are familiar on the earth. The lines in stellar and nebular spectra which have not yet been identified are extremely few, and there is strong probability that their number will be still further reduced. Not only is this true of our own stellar system, but the spiral nebulæ, which are believed by many astronomers to be distinct universes, also show lines which we can match in terrestrial laboratories. When we consider the enormous extent of space covered by modern observations, and the extreme diversity of the physical conditions existing in the different bodies examined, we cannot but realise that there must be some deep significance in this remarkable fact. Does it mean that the whole of the physical universe arose from a common origin? Or is it that Nature is restricted in her operations, so that she cannot produce material existences of a different type from those of which the earth is composed? At present we cannot decide between these alternatives.

It is not surprising that, in their early enthusiasm at the tremendous possibilities opened up by spectrum analysis, chemists should have entertained hopes which have not as yet, at any rate, been realised. Sober reflection shows us that the power of the spectroscope is limited in more than one direction. The spectrum tells us nothing, for example, of the chemical composition of the greater bulk of the sun and stars; namely, the inner portions, which give rise to the continuous background of the spectra. We can only analyse the thin outer envelopes or atmospheres of these bodies. Nor can we even be sure that our information there is complete. The hypothetical element, coronium, for instance, is represented in the solar spectrum only by bright lines produced from the sun's corona during an eclipse. It gives no absorption lines, and if we had no moon to shut out the body of the sun's light, we might even now be ignorant of its existence. Who can say what substances present in the stars may be hidden from us in the same way? Again, we know now that there is a very large amount of dark matter in the universe. With regard to this, and to the composition of millions of faint stars which our large telescopes reveal to us, the spectroscope is silent. Once it was hoped that a means might be found of analysing a substance through light reflected from its surface, and that in this way the planets could be brought to yield up the secret of their composition. But here also our hopes have met with disappointment, except in so far as absorption by planetary atmospheres has lifted the veil a very little. Even our nearest neighbour, the moon, is a complete stranger to us. The fact is that the spectroscope, after bestowing its early affection on chemistry, has transferred its favours to physics. The later developments of spectroscopy have thrown no end of light on the physical characteristics and order of development of the stars. So intimate is our present knowledge of the processes taking place in a luminous body that it is probable that, even had the heavenly bodies yielded only unfamiliar spectrum lines corresponding to no known elements, we should still, in time, have been able to analyse the spectra and form ideas as to the evolution of the physical universe.

So far as chemistry is concerned, however, it is possible that the recent progress of astrophysics may throw some light on the order of the evolution of the elements. The study of a large number of stellar spectra has shown that the spectra can be arranged in a continuous sequence, in which the transition throughout, from one end to the other, is perfectly gradual. The spectra of more than 99 per cent. of the stars examined are included in this sequence, and the few outstanding ones, though of great interest from a physical point of view, can be ignored for our present purpose. The temperatures of the stars whose spectra are thus classified are also found to be in regular order. Thus, denoting arbitrarily-made divisions of the succession by the letters B, A, F, G, K, M, we find that, from the B to the M stars, the temperature falls continuously. The characteristics of the various classes of spectra are as follows. In the very hottest stars —of which comparatively few exist, and which precede the sequence we have mentioned—we obtain bright lines of hydrogen and helium, together with evidence of an unknown substance. In the B stars hydrogen and helium are still predominant, but faint lines of other elements appear also. These are somewhat strengthened in the A stars, though the hydrogen lines still form by far the most conspicuous feature. The hydrogen lines are considerably less predominant in the F stars, and the metallic lines are much stronger. The G stars, *e.g.*, the sun, show the metals as conspicuously as they do hydrogen. The same tendency is continued in the K group, whilst in the M stars bands of compounds —particularly titanium oxide—make their appearance. We have thus a regular progression, with decreasing temperature, from a marked predominance of the lightest elements to a more or less uniform distribution of a variety of substances.

It is inevitably suggested by these facts that in the stars elements are being made or broken up. There is strong reason to believe that each star passes through the spectral sequence twice—first from M to B, and then back to M again. If, then, we are to take the spectra at their surface value, it would seem that in the upward stage the elements are being broken up into lighter ones, and that recombination takes place as the star descends the scale of temperature again. If this is so, a large amount of energy must be released during the building-up process, and we could account very satisfactorily for the maintenance of the heat of some of the stars, such as the sun, in spite of the enormous amount of energy they radiate continuously into space. The hypothesis has obvious attractions. But we must remember that the spectrum is not an infallible guide to the complete composition of its source. The fact that the spectrum of a star consists mainly of hydrogen does not necessarily mean that the star itself is so constituted. In this connexion a suggestion recently advanced by Dr. Saha, of Calcutta, is of very great interest.

The atom, as is well known, is now believed to consist of a central core of positive electricity, surrounded by an equivalent negative charge in the form of electrons, whose number varies from element to element. The core practically determines the atomic weight, whilst the chemical and spectral properties of the atom are due to the outer electrons. At high temperatures there is a tendency for an atom to become *ionised*, *i.e.*, to lose one of its electrons, by the vigour of its collisions with neighbouring atoms. When it does this its spectrum is considerably modified and the substance becomes, in fact, for spectroscopic purposes, a new element. At a still higher temperature another electron may become detached, and then virtually a third new element is produced, and so on. Now the successive spectra, due to the neutral, singly-ionised, doubly-ionised, etc. atoms, tend to lie farther and farther in the ultra-violet region as the amount of ionisation is increased. But, owing to the absorption of the shorter waves by the earth's atmosphere, we are unable to obtain solar and stellar spectra beyond a short distance in the ultra-violet. Consequently, the spectrum of a star which appears to us to contain practically nothing but hydrogen, may actually contain lines, in the far ultra-violet, due to a large number of ionised substances of which we can obtain no knowledge. Hydrogen, however, is not affected in this way to anything like the same extent as the heavier elements, for, since it contains only one electron, it would, if it lost that, cease to be an element at all and would have no chemical or spectral properties. At very high temperatures, therefore, the visible spectrum of a mixture of substances would appear to be dominated by hydrogen. On this view the spectral evidence of the absence of a substance from a star is not to be accepted as final.

We are dealing here with problems of very great difficulty. The time has not yet come when decisive answers can be given to them. Nevertheless, the rate of progress during the last few years has been so rapid that it would be unwise to conclude too hastily that they are beyond solution. Chemistry has, at any rate, a new direction for its activities, and it is not improbable that in the stars it will find the answer to questions which, in the laboratories of earth, could hardly have arisen.

THE RECOVERY OF PRECIOUS METALS FROM PHOTOGRAPHIC AND OTHER TRADE-WASTE SOLUTIONS.

E. GARDNER.

Comparatively large quantities of silver, gold, and platinum are used in photography, glass-silvering and chemical gilding, electroplating and other industries, but relatively very small amounts are recovered from spent solutions owing to ignorance of simple and cheap methods of recovery. In the first three trades mentioned above, over 2 million ounces of silver nitrate, worth £200,000, is consumed yearly in Great Britain; of this amount more than three-quarters is used in photography and most of the silver content is lost irretrievably.

Photography.—The spent solutions produced by the photographer comprise toning-baths, fixing-baths, and various washing waters. Taking an average print on self-toning paper, about 85 per cent. of the silver originally present goes into the preliminary wash-water and fixing baths, 5—8 per cent., remains on the print, and the remainder passes away in the final washing.

Of the methods of recovery recommended in text-books on photography, precipitation of silver from fixing-baths and wash waters by means of "liver of sulphur" does not produce a precipitate that settles well, and contamination with polysulphide, or any sulphides, is to be avoided where photographic materials are used. Precipitation of gold from toning-baths by ferrous sulphate is not satisfactory for cold and very dilute solutions, especially when thiocyanates are present; and there are much better reducing agents than ferrous oxalate for precipitating platinum.

The method recommended by the writer is to collect all solutions in a wooden vessel and to precipitate with clean scrap iron. Reduction is complete within 24 hours, heating is unnecessary, and the precipitate settles very satisfactorily. Two wooden casks should be used for continuous photographic work, one being used for charging and precipitating while the precipitate is settling in the other. The clear liquid is siphoned off.

At the yearly clean-up the precipitate is passed with water through a coarse sieve (6 holes to the linear inch) to separate undissolved iron, drained on a calico filter, washed with hot water, placed with the cloth in an enamel dish, and dried at a gentle heat. The precipitate should not be dried completely otherwise it may ignite spontaneously. It consists of impure metallic silver and possibly gold and platinum, and is technically termed "foots," an Anglo-Saxon word meaning the dregs or lees settling from a liquor. The operation of obtaining the precipitate may be called "footing."

The precious metals on paper cuttings, spoiled prints, etc. may be recovered by incinerating the material, if necessary after moistening with a solution of alkali nitrate, and adding it to the footing cask. Great care is required in burning celluloid films. Spoiled plates should be fixed, but negatives are not worth stripping. Batches of spoiled emulsion should be liquefied in warm water and treated with scrap iron in a separate cask, as they are very rich in silver. It is recommended that the collected precipitates be sent direct to a refinery; it is useless to send dilute solutions to a refinery as the freight on these will leave no margin of profit.

Glass-Silvering and Chemical Gilding.—In this, the next largest of the industries using gold and silver compounds, the bulk of the metal is retained on the article manufactured and the solutions used are to a large extent self-precipitating. All spent solutions and ashes are put into the foots barrel, as described above, and preferably with the addition of a little sodium chloride. The ashes will include those of sawdust, which is, or ought to be placed wherever solutions containing precious metals may drop or be spilt, as well as those of old polishing cloths, aprons and leathers. It should be noted that sawdust saturated with silver nitrate is very inflammable when dry. Handwash is collected in a separate vessel in which it is not necessary to use iron for precipitation, and settling can be facilitated by adding a very little lime. At the clean-up the rate of filtration can be accelerated by mixing some coarse sawdust with the precipitate. The whole is then dried, burned, and the ashes collected. Gold and silver stains on the hands can be readily removed with a very dilute solution of potassium cyanide, to which a few drops of hydrogen-peroxide solution have been added, and these washings can be put in the foots barrel. Finally, the foots barrel, after it has been in use for several years, should be burned and the ashes collected.

Gilding and Electroplating.—The electroplater has as a rule some knowledge of chemical manipulation and facilities for heating batches of liquor. For the recovery of precious metals from cyanide baths, many text-books recommend the addition of sufficient acid to decompose half the cyanide, and so precipitate the insoluble gold or silver cyanide. This method is to be condemned as very dangerous owing to the evolution of hydrogen cyanide. It is true that the recovery is fairly complete with silver, but the clear acid liquor has to be treated subsequently with scrap iron in the case of gold. Another method recommended is to evaporate the bath to dryness and to fuse the residue in a crucible; this is impracticable in many workshops. A more convenient method is to heat these solutions with zinc dust with frequent stirring, when a complete although slow precipitation is obtained. A very rough test to ascertain if precipitation is complete is to acidify a sample of liquid with hydrochloric acid; absence of precipitate indicates complete precipitation of the precious metals.

All neutral or slightly acid silver solutions, other than cyanide, should be acidified and precipitated as chloride. Desilverising acid or "stripping" solution must, if necessary, be diluted before precipitation, and the filtrate obtained must be neutralised or further diluted before passing to the drain. The precipitated chlorides may be drained and sent to the refiner, or reduced to metallic silver with scrap iron.

Solutions from platinum-plating, which often contain much phosphate, can be precipitated with zinc dust, but complete reduction is difficult. In some workshops electrolytic reduction, using an insoluble anode, is carried out and found satisfactory.

Filtration of Precipitates.—A few instructions on the making of square calico filters for these precipitates may be of use.

A square wooden frame is made of such size that its corners will just rest on the edge of the deep circular vessel into which it is proposed to filter. The frame may be, for example, 14 in. square and 3 in. deep and made of batten 1 in. thick, thus leaving an inner opening of 12 in. square.

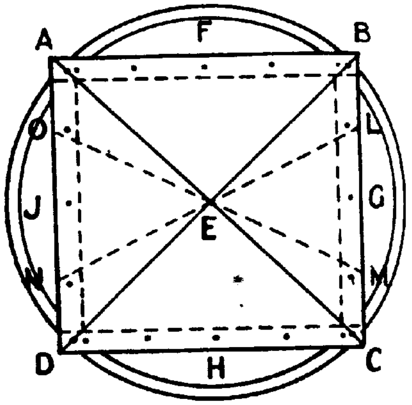

FIG. 1.

Top view of filter. Scale ⅛.

From a piece of new, closely woven calico, washed to remove dressing and dried, cut an exact square of 24 in. side, mark the middle of each side and the middle of each upper edge of the frame, which may be conveniently standing on the circular vessel (Fig. 1). Taking the middle of each cloth-edge in turn, and doubling ½ in. underneath to strengthen it, fasten it temporarily by means of copper tacks to the middle-points, F, G, H, J, of the upper edges of the frame, leaving the slack of the cloth hanging inside.

On the side AB, draw the cloth-edge tight from its central tack, double ½ in. underneath as before, and fasten it with a tack almost at the corner B; repeat this with the other half of the same edge towards corner A. Turn the frame round and deal similarly with side CD. These two sides are now finished and are represented in the diagram of the unfolded cloth taken from the frame by the same letters (Fig. 2).

Taking side BC, hold the cloth-edge in one hand at a point B_1 (Fig. 2), 6·5 in. from the central tack, double ½ in. underneath as before, slightly raise it from the frame, and with the other hand fold neatly along the line EP. Bring the point B_1 exactly down to the corner B of the frame and fasten it there with a tack; treat the similar points C_1, D_1, and A_1 in the same way.

The cloth ought now to form a perfectly regular inverted pyramid inside the frame, and if not, some slight adjustment must be made. Each side will consist of one layer of cloth, but underneath the smaller triangles EBL, EMC, EDN, and EOA, in Fig. 1 there will be two extra layers. Drive the tacks home, add a few extra ones, and trim off the four ears of cloth which project beyond the frame (the triangles AA_1T, BB_1P, CC_1R, and DD_1S in Fig 2).

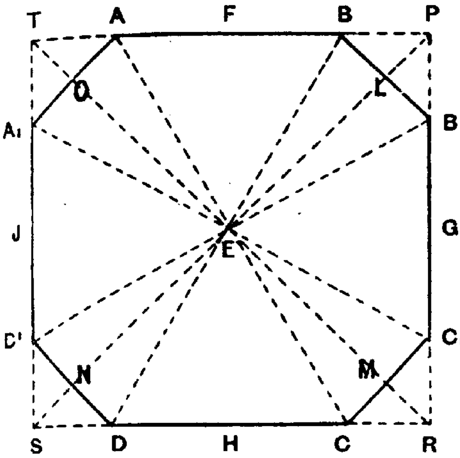

Fig. 2.

Filter cloth removed from frame, showing folds. Scale ⅛.

The filter is now ready for use. Some boiling water is first passed through. Then a little precipitate is put in to form a filter bed, and as soon as the filtrate runs clear the filtration is proceeded with, care being taken that the filter does not run dry before all the precipitate is placed on the cloth. Finally, remove the soluble salts by washing a few times with hot water.

In packing precipitates before sending them to a refinery, care should be taken not to use metal boxes. A precipitate like moist silver chloride rapidly attacks iron or zinc, and foots powders often retain sufficient acid to corrode a metallic container. Well-made wooden boxes or jars of glass or earthenware should be used.

SAFEGUARDING OF INDUSTRIES ACT.

BORIC ACID.

On May 27, 30 and 31, Mr. Cyril Atkinson heard the complaint of the Chemical Merchants' and Users' National Vigilance Committee, represented by Mr. K. Swan and Mr. R. L. Parry, that boric acid had been improperly included in the list of articles dutiable under Part I. of the Act. The opponents, represented by Sir Arthur Colefax and the Hon. S. Cripps, were Howards and Sons, Ltd., H. Coghill and Son, Ltd. (Newcastle, Staffs.), G. H. Poole and Sons (Bootle), and Joseph Townsend, Ltd. (Glasgow). Mr. Whitehead represented the Board of Trade.

Mr. Swan, for the complainants, said that the boric acid imported into this country, mostly of 99·5 per cent. purity, came from the Larderello district of Tuscany, but the importation had ceased since the passing of the Act. The point at issue was whether this acid was a fine chemical or not; he held that it was not. Boric acid was used mainly for the following technical purposes:—(1) For preserving butter and other foodstuffs; (2) in pharmacy; (3) in toilet preparations; (4) for glazing and enamelling pottery; (5) in the glass industry; (6) in metallurgy; (7) for leather manufacture; (8) in the soap industry; (9) for paper-making; (10) in the manufacture of candles; (11) for making borax; (12) as a ball-room floor polish. It was not normally, if at all, used as an analytical reagent; it had not been treated by the trade as a fine chemical, and was not manufactured by fine-chemical manufacturers. It was not generally dealt in or handled by dealers in fine chemicals, but was almost always sold by the producers or their agents direct to the consumer. It was obtained mainly from Tuscany, but also from natural borax by the simple processes of acidification and crystallisation.

Evidence was then given by representatives of four firms of chemical dealers, who stated that in their opinion boric acid was a heavy chemical; and various references in trade journals were adduced in support of this view. It was, however, elicited that in this country dealings in boric acid for the home trade were very rare and for relatively very small quantities.

Signor U. Funajoli, managing director and head of the electrical department of the Società Boracifera di Larderello, Florence, described the occurrence and extraction of boric acid from the natural springs and *soffioni* in Tuscany, and emphasised the simplicity of the process that was utilised in producing acid of 99·5 per cent. purity. He stated that during the war his firm exported about 80—90 tons a month to the United Kingdom, and that this trade existed before the war. About 10 per cent. of the boric acid exported consisted of 82 per cent. material, which was labelled "crude" and made by mixing the 99·5 per cent. acid with the lowest grade material of 55 per cent. purity. All the output was sold to Borax Consolidated, Ltd., and unless chemically pure boric acid was asked for no tests were made for the presence of lead and arsenic; if these were present they were eliminated by further crystallisation. His company's works were under the Government Mining Department and were not regarded as chemical works. Counsel for opponents elicited that since the Act was passed boric acid had been sent into this country invoiced as sassolite, a mineral containing about 80 per cent. of boric acid. Practically all the material exported from Italy was produced by his company. Before the war more crude acid than refined was exported; during the war the proportion of refined rose considerably, this product bringing in the greater profit; but recently increased labour costs had militated against the production of the refined material.

Mr. E. J. Parry agreed with the previous evidence, excepting the statement that arsenic and lead could be removed by crystallisation. The uses of boric acid in this country were distributed approximately as follows:—preservatives 60 per cent.; medicine and pharmacy 30 per cent.; other uses 10 per cent. Witness quoted a number of printed references to the classification of boric acid as a heavy chemical, and stated that in this Society's *Journal* abstracts concerning it were placed in Section VII., in which heavy chemicals were for the most part treated.

Sir A. Colefax said that his case was that boric acid was a fine chemical. No attempt had been made to describe how the Italian material was purified. As carried out in this country the manufacture was extremely difficult inasmuch as lead and arsenic had to be eliminated. As Mr. Parry had admitted, the B.P. quality was not sufficiently pure for preservative purposes. Imports from Italy were about 40 per cent. of the total importation, but only a fraction of the quantity manufactured here.

Mr. Alfred Howard, director of Howards and Sons, Ltd., said that his firm had been manufacturing boric acid for more than 40 years and that over 90 per cent. of the production, which was all of B.P. quality, was sold to wholesale druggists; the raw material used—boracite or colemanite—was purchased from Borax Consolidated, Ltd. Even if not of B.P. standard, he regarded boric acid as a fine chemical because it required much careful preparation. Similar evidence was given by Mr. H. Poole, whose firm manufactures boric acid for use as a food preservative. Mr. T. E. Lescher, director of Evans Sons, Lescher and Webb, Ltd., said that his company dealt in, but did not manufacture, boric acid—chemically pure, pure B.P., and commercially pure. The last-named was generally of B.P. quality, but the purity was not guaranteed. He regarded boric acid as a fine chemical because it was mainly used for medicinal and preservative purposes, and it had to be extremely pure. If such a chemical were used mainly for industrial purposes he would regard it as a heavy chemical, but he would still consider boric acid a fine chemical even if 50 per cent. of the production were used in industry.

Mr. B. D. Jones, secretary of Burton, Baker and Co., said that his firm used annually 300 tons of boric acid for food preservation, all of which was purchased from Borax Consolidated, Ltd., and Mr. F. Dickens, of Darton, Gibbs and Co., antiseptic surgical dressing manufacturers, stated that his company used 50 tons per annum. Mr. P. A. W. Self submitted results of analyses of commercial boric acid showing the high degree of purity of this grade, nearly all of which is apparently up to B.P. quality. On this account he held boric acid to be a fine chemical. If pharmaceutical chemicals and antiseptics were excluded from the list of fine chemicals, practically only analytical reagents would be left in it. Mr. F. A. Hocking, pharmacist to the London Hospital, stated that that Medical School consumed 2¼ tons of boric acid yearly; and Mr. Edmund White, managing director of Hopkin and Williams, Ltd., expressed the view that boric acid was a typical fine chemical.

Mr. H. F. Johnson, sales manager to Borax Consolidated, Ltd., said that his company controlled many boric-acid manufacturing plants, partly through subsidiary companies and partly by working arrangements. About one-fifth of all the boric acid imported into this country came from Italy, which provided about 11 per cent. of the world's consumption. Of the boric acid consumed in the United Kingdom, 36·22 per cent. was used in medicine and surgery, 34 per cent. for food preservatives, and 6·78 per cent. for boric lint; but of borax, 82 per cent. was used for industrial purposes (pottery 25%, enamelling 14%, dyes 1%, glass 1·78%, metal industries 3·6%, paint and varnish 1·79%, and starch 10%). His firm controlled 85 per cent. of the sales of boric acid in this country, and all of it was up to the old B.P. standard. Much more of the acid manufactured here was used for pharmaceutical than for industrial purposes. A letter from the witness to the Larderello Co., written in October last, was then produced, in which he stated that the principal use was for industrial purposes, and that its importation should be free. The report of the directors of his company for 1921 was quoted to the effect that the medicinal uses of boric acid were ancillary to its industrial uses, and it was stated that the company had lodged a complaint with the Board of Trade asking that boric acid be removed from the list as it was in no sense a fine chemical. The witness explained that at that time he was importing boric acid, and that the complaint had been dispatched without proper consultation with his technical colleague, who had afterwards objected. Subsequently pressure was brought to bear by the manufacturers in this country, and the complaint was withdrawn. The industrial uses of boric acid in this country were—pottery 3·7, enamelling 0·42, glass 3·65, and tannery 4·84 per cent. respectively of the total consumption. Of borax and boric acid combined about 60 per cent. was used for industrial purposes.

The process of manufacture in this country was then described *in camera* by Mr. H. Derring, works manager and chief chemist to Joseph Townsend and Co., Ltd., of Port Dunder, Glasgow. Dr. H. Bassett, professor of chemistry in University College, Reading, supported the view that the process conducted in this country was a fine-chemical process because its conduct involved continuous, skilled chemical supervision. In his view boric acid was a fine chemical because of the complexity of the process of manufacture; because the bulk of it was used for purposes which demanded very great purity, and most of these purposes were real chemical purposes, its uses in pharmacy and as an antiseptic being based on its chemical activity. His views on the general question of what is a fine chemical had been arrived at since the Act was passed, and he had followed with much interest the reports of the discussions which had been held by Sections of the Society of Chemical Industry. He did not think that references to trade catalogues threw much light upon the subject.

In his final speech Sir A. Colefax said that the complaint concerned only a fraction (one-fifth in 1920) of the boric acid consumed in this country. The object of the Act was to safeguard *home* industries, and over 80 per cent. of the consumption was made here by a process which differed entirely from the Italian process, and which required continual skilled chemical supervision, *i.e.*, supervision which was not confined to analytical tests, but which involved the application of the results of such tests. Whereas all the boric acid made here was of B.P. quality, the Italian product was not tested for lead and arsenic. The witness who had spoken about the Italian process had not described it but had only given some very inadequate details. The nature of the process used and the degree of purity of the product were very important considerations.

Mr. Swan objected that the Board of Trade had not called any witnesses to support the contentions advanced in its counter-statement. On the question of skilled supervision he said that it appeared from the opponents' statements that by increasing the number of chemists employed in a works and introducing new complications into the process any chemical could be brought within the category of fine chemicals. He held that there was practically a complete parallel between this case and that concerning tartaric and citric acids (*cf.* J., 1922, 115 R). The use of boric acid for preserving food was regarded by the trade as a commercial use, and the substance had always been regarded by it as a heavy chemical. The evidence on that point remained uncontradicted, and there, he thought, the case should end.

The referee's decision, signed on June 20, ran as follows:—

I have said in previous cases that *primâ facie* a substance is not dutiable on importation into this country and that it becomes dutiable under the Act in question only if there is no reasonable doubt about its being covered by the words in the schedule.

The complainants base their case against the inclusion of boracic acid in the list of dutiable substances upon trade usage. They contend that there has been such a general classification or acceptance of boracic acid as a heavy chemical as to make further consideration unnecessary and irrelevant. The evidence stands thus. Four chemical merchants of experience say that they have always regarded boracic acid as a heavy chemical; three of them go further and say that it has always been treated and regarded in the trade as a heavy chemical. Mr. Parry said the same thing. Mr. Johnson, the sales manager of Borax Consolidated, controls and sells 85 per cent. of the boracic acid sold in this country. Surely he, if anyone, must be familiar with the trade view. Until a few weeks ago, before certain pressure was put upon him, his view was that boracic acid could in no sense be regarded as a fine chemical.

On the other hand, five or six witnesses were called who expressed the opinion that boracic acid was a fine chemical, but not one of them said that it had been so classified or treated by the trade.

The witnesses for the complainants are supported by the evidence to be derived from trade journals. It is, in my opinion, established that trade literature has consistently referred to boracic acid as a heavy chemical. I am not forgetting that it appears in lists of pharmaceutical chemicals, but that fact is almost colourless.

Further, the report issued by the Department of Overseas Trade on the market for heavy chemicals in the Argentine Republic deals with boracic acid as a heavy chemical.

I am satisfied and find as a fact that boracic acid has not been generally regarded as a fine chemical in the trade. The complainants further rely upon the following contentions:—

(a) That the scale of manufacture is undoubtedly large for a fine chemical. This was emphasised by Borax Consolidated in their abandoned complaint.

(b) That about one-fifth of the boracic acid consumed in this country comes from Italy and that whatever may be said of the difficulty of manufacture here the method of production there certainly does not tend to stamp boracic acid as a fine chemical.

Although criticised at a later stage, the evidence of Mr. Funajoli was not seriously challenged in cross-examination. It certainly satisfied me that the production in Italy is simple and does not require that skill and expert supervision which is usually associated with fine-chemical production.

Now, what is there to displace this strong *primâ facie* case for establishing that boracic acid ought not to be included in the list as a fine chemical?

The Board of Trade put in a counter-statement prepared with its usual care and lucidity.

The ground relied upon as justifying the inclusion of boracic acid in the list is that 80 per cent. of the total consumption in this country is absorbed for medicinal and surgical purposes and that a considerable quantity is used for food preservation purposes and only insignificant amounts in the industries.

It is clear that the Board has been misinformed as to the facts.

I accept the evidence of Mr. Johnson that 43 per cent. is used for medicinal and surgical purposes, including lint, 34 per cent. for food purposes, and 23 per cent. for industrial purposes. Even these figures establish that over three-fourths of the consumption of boracic acid is for purposes requiring a high degree of purity.

At the hearing the opponents relied also upon the method of manufacture in England, contending that it required that skilled supervision which is one of the indications that the product is a fine chemical.

I cannot say that I am at all convinced by the evidence on this point. Dr. Bassett certainly said that the operations to prepare boracic acid were extremely complex and required very careful supervision, but when asked what part of the operation was complex he answered that one stage might reasonably be called complex, the stage where arsenic was removed. Now, curiously enough, Mr. Derring, who actually supervises the manufacture, made light of that and said that the removal of arsenic was very simple.

On this point of difficulty I cannot forget the first complaint of Borax Consolidated. That complaint states that the method of production is one of the simplest operations and does not require chemical supervision. I cannot believe that steps such as the formulating and lodging of that complaint were taken without careful consideration. I asked Mr. Johnson if he had made the complaint on his own authority. His answer was "I did, and I did not." I do not know what that means, but he admitted that the managing director was consulted, and I do not believe that the statement did not represent the view of those responsible for it at the time. Having carefully considered the evidence given and bearing in mind the fact that difficulty of manufacture was not put forward by the Board of Trade in its statement and the attitude first taken up by Borax Consolidated, the conclusion I come to on the method of manufacture is that it does not help to weight the scales in favour of boracic acid being a fine chemical.

There remains, however, the very formidable point I have indicated, viz., the fact that three-fourths of the consumption is for medicinal and food purposes demanding considerable purity as a matter of vital importance. Ought this to outweigh the trade classification or usage? I think not. If I could persuade myself that the attainment of the necessary purity required the skilled labour and constant supervision by trained chemists demanded by fine-chemical production I might take a different view. Dr. Bassett put the matter admirably, but I am not persuaded as to the complexity of the operation. He has not seen it, and I repeat it is curious that the complexity he singles out should be described as simple by Mr. Derring. The complainants had no notice that the question of difficulty of production was to be raised. They came quite unprepared to deal with it. The opponents cannot therefore complain if the evidence they adduce is regarded somewhat critically.

On the whole I think that boracic acid is not a fine chemical within the Act, but whether I am right or wrong about that, I am quite satisfied that the position of boracic acid is at least so doubtful that it ought not to be included in the list of dutiable substances and I award that it be removed.

SCIENTIFIC GLASSWARE.

In this case, Jules Lang & Co., represented by Mr. K. Swan, complained of the inclusion in the list of reagent bottles, hydrometer jars, cylindrical measures and conical measures (bell-shaped). Mr. Courtney Terrell appeared for the Board of Trade. The complaint was heard on May 29 and the Referee's award is dated June 12.

Mr. Swan asked for a definition of the term "scientific glassware"; did the word "scientific" apply to the mode of manufacture or to the use? Certain bottles and stoppered jars which were used by confectioners, etc. closely resembled laboratory ware and the Customs were levying duty upon them, although they were not intended for scientific use. He suggested that the appellation "resistant" might suffice to distinguish between the two classes.

In giving evidence for the complainant company, Mr. E. J. Parry defined scientific glassware as glassware which resisted sudden changes of temperature and the action of chemicals, or which was used primarily for carrying out a scientific operation. All the articles mentioned in the complaint were scientific glassware excepting cylindrical and bell-shaped glass measures, but reagent bottles must consist of resistant glass and museum jars must be made of very clear and resistant glass and be provided with air-tight stoppers. Mr. Bush, managing director of Henry W. Bush & Co., Ltd., said that his firm imported reagent bottles and sold them to dealers who supplied them to laboratories, and to pharmacists, etc. as "shop rounds." Bottles consigned to him had been held up by the Customs and he had been fined for not declaring them. His chief business was graduating cylindrical measures imported from America, Belgium and Sweden, and the degree of accuracy of the finished article was 3 to 4 per cent. Mr. F. Lang, proprietor of Jules Lang & Co., said that he had been fined by the Customs for importing, without declaring, stoppered cylinders which were not made for scientific purposes; and stoppered white glass bottles, invoiced as reagent bottles but not intended for use as such, had been treated similarly. His firm had started the manufacture of scientific glassware in 1918, but had since given it up.

Evidence for the Board of Trade was given by Mr. J. H. Gardiner, technical director of James Powell & Sons, Whitefriars, Ltd., who explained that his firm had separate departments for manufacturing domestic and scientific glassware, respectively, and that all the objects mentioned in the complaint were made by the scientific branch from special glass by processes requiring care, precision and accuracy. Mr. D. H. Baird, of Baird & Tatlock (London), Ltd., gave similar evidence. At the instigation of the Government he had started the manufacture of scientific glassware ("Duro" glass) during the war, but had sold that part of his business in 1920. The term "reagent" bottle connoted a specific quality of bottle. True reagent bottles could not be made in the same mould as ordinary bottles; they were practically lead-free, were resistant to the action of chemicals, and were provided with accurately-ground and numbered stoppers. Vendors of ordinary glass bottles did not use the term "reagent bottles." Sir Herbert Jackson said that he could not give a hard and fast definition of scientific glassware, but any glassware traditionally known as such, which had been made with great care, was of high quality and used for scientific purposes was scientific glassware. "Traditionally used for scientific purposes" was the essence of the description. All glass apparatus made for laboratory use, even for use in school laboratories, was scientific glassware. A reagent bottle must be made of clear glass, be accurately stoppered, be appropriately and properly annealed, and capable of withstanding changes of temperature. He would not specify freedom from lead, because some lead glasses were quite safe for laboratory use.

The following is the text of the award:—

In my opinion the question whether the descriptions complained of are properly included in the list of dutiable articles depends upon the meaning of the words used. I am satisfied that all the descriptions complained of are properly included in the list provided that these descriptions are used strictly and within the limits which are defined in this award. Reagent bottles are properly in the list provided that by the expression "reagent bottle" is meant a bottle which is reasonably fit for containing chemical reagents. The legal obligation implied on the sale of such bottles is that the bottle shall be reasonably fit for containing any ordinary chemical reagent, not fit for just a few but fit for any chemical reagent, except possibly some exceptional substance calling for special and exceptional qualities in its container. This obligation means that the bottle must be made of hard suitable glass free from lead. By "free" I mean containing no more than such a trace as does not matter. The neck and stopper must be ground so as to make a perfectly air-tight joint. If a bottle does not fulfil these requirements it is not suitable for containing chemical reagents, and is not scientific glassware. I gather that the distinctive shapes of reagent bottles have been copied and that the description has been applied to inferior bottles and that these practices have led to trouble with the Customs. That trouble is not for me to deal with.

A hydrometer jar means a jar suitable for hydrometer tests. It is of distinctive type, straight sided, of circular or elliptical section and from six to ten inches high. The glass must be good and very clear. The jar must be a very good cylinder and must be capable of standing rapid changes of temperature.

Museum jars, specimen jars and surgical jars.—It is very possible that there is a practical difficulty in the case of these jars because the customary shape and description have been borrowed for all sorts of purposes which are not scientific and do not require scientific glassware. Any jar which is suitable for containing and displaying scientific specimens, not just a few specimens, but any scientific specimen not calling for exceptional treatment is a museum or specimen jar.

All three jars require the same qualities, *i.e.*, they must have clear fronts so that there is no distortion caused by the glass. The edges must be ground very flat and true so that the glass plate laid on them will give an air-tight fit and prevent evaporation. The glass must be sufficiently well-made to prevent contamination of the liquid, if any, containing the specimen.

Cylindrical measures (bell-shaped) and conical measures.—I think that these measures are on the border line, and that the only articles of these descriptions which can properly be considered as scientific glassware are measures which are in fact graduated with scientific accuracy. It is the correct graduation which, according to the evidence, makes them scientific glassware. I award that the descriptions complained of are properly included in the list if and when defined within the limits I have laid down. The complaint therefore fails.

MEETINGS OF OTHER SOCIETIES.

SOCIETY OF GLASS TECHNOLOGY.

At the meeting held in Sheffield on June 21, Prof. W. E. S. Turner announced that the visit of the American Ceramic Society to this country, which was fixed for September of this year, had been postponed until 1923. It was decided to renew the invitation and to ask the Ceramic Society to join in the invitation and the arrangements for the meeting.

Mr. Y. Amenomiya, a Japanese member, contributed a paper on the devitrification caused upon the surface of sheet (window) glass by heat, in which he stated that he had found devitrification to take place at between 700° and 800° C. Mr. R. Kamita described an investigation on the influence of alumina in preventing the devitrification of sheet-glass during the drawing process. He showed that the temperature of devitrification of a standard glass increased with increasing amounts of alumina, and that 5 per cent. of alumina caused the devitrifying temperature to rise by approximately 100° C.

The swelling produced by adding water to sand was discussed by Mr. L. E. Morton, who pointed out that the subject was important as manufacturers still measured out batch materials instead of weighing them. From studies of three typical sands, he concluded that sand containing added water would more than fill a vessel which would contain the same sand when dry, the excess being as much as 12 or 15 per cent. of the total dry sand. The three sands seemed to swell to a maximum extent when about 5 or 6 per cent. of water was added.

In a short paper on the mixing of batch, Prof. Turner compared the efficiency of hand-mixing with machine-mixing. In three samples from a batch mixed by hand the maximum variations were: sand 44—77 per cent.; lime 4·8—8·3 per cent.; whereas in a similar batch mixed mechanically the sand varied from 69 to 73 per cent. and the lime from 4·2 to 6·6 per cent. Machine-mixing, by giving a more regular batch, assisted melting and materially reduced the time required for producing good glass.

THE FARADAY SOCIETY.

A meeting was held in the rooms of the Chemical Society, Burlington House, on June 26. Five papers were read; a sixth paper, on the electrical conductivity of hydrochloric acid and potassium chloride in the presence of sucrose, being taken as read, as the author, Mr. A. J. Kioran, was absent.

Prof. A. W. Porter and Mr. J. J. Hedges presented a paper on the law of distribution of particles in colloidal suspensions, with special reference to Perrin's investigations. Perrin has shown that, when particles are distributed in a dilute colloid solution, the law of distribution is the same as that of the distribution of the molecules in an atmosphere; later, Burton showed that this law does not hold for any considerable distance from the surface, and in the present paper the authors attempt to ascertain the actual distribution from the surface downwards. In the experiments a dilute solution of gamboge was employed and the particles were counted by means of a modified form of ultra-microscope. The results found can be fitted fairly closely to a curve having the equation:—

$$\log_e \frac{n}{1 - bn} + \frac{1}{1 - bn} = Ky + A$$

where n is the number of particles per c.c., y is the depth, and b, K, and A are constants. Although b may be considered as representing the volume of a suspensoid particle plus the ocean of second phase surrounding it, and attached in some way to it, the authors consider it merely as an empirical constant.

A paper describing the electrochemical effects produced by superimposing alternating currents upon direct currents during electrolysis was read by Mr. W. R. Cooper, who classifies the effects according as the alternating current is smaller than, equal to, or greater than the direct current. In all three classes no great difference is found in the amount of copper deposited in an electrolytic cell when a low frequency alternating current is superimposed on the direct current, but an increase of current is obtained irrespective of the relative values. This effect does not pass off as soon as the alternating current is switched off, but dies down during a period which may last for several minutes. Microscopical examination of the electrodes during electrolysis showed the hydrogen bubbles clinging to the platinum electrodes and the oxygen bubbles escaping much more easily. The most interesting observation made with high-frequency alternations was when a very fine wire, just dipping into dilute acid, was used as one electrode, and a comparatively large piece of platinum foil as the other. Under certain conditions a large bubble formed in the electrolyte and travelled up to the electrode. This seemed to result from an audible discharge, which could be seen if the experiment were carried out in the dark.

Prof. T. M. Lowry and Prof. E. E. Walker read a paper on "The Expansion and Shrinkage during Caking of Potassium Carbonate." A sample of potassium carbonate, which had been kept in a paper bag for four or five years, was emptied into an earthenware jar. Five days later it had fractured the jar, and continued to expand after the walls had fallen away. About this time the heat of the laboratory was shut off, and three weeks later the salt began to shrink, and eventually contracted to less than its original volume. Attempts were made to produce expansion in various modifications of potassium carbonate, but without success, though a possible explanation assumed the presence in the material of a sesquihydrate which expanded on conversion into the dihydrate.

In a paper entitled "The Powdering of Minerals by Decrepitation," Prof. T. M. Lowry and Mr. L. P. McHatton described the decrepitation of barytes by heat and attributed it to the presence of occluded water. A semi-quantitative relationship was found between the water content of the barytes and the fineness of the powder produced. Quantitative experiments were also described on the relationship between the loss of weight and the fineness of the powder produced by the decrepitation of celestine, croceite, and common salt.

The last paper was on "The Systems in which Metals Crystallise," by Dr. J. L. Haughton and Miss G. W. Ford. In most cases the system in which a metal crystallises depends on its position in the periodic table, and alloys that form a homogeneous series of solid solutions right across the diagram crystallise in the same system. There does not appear to be any relationship between the changes which occur in the physical properties of metals at the melting-point and their crystalline habit, with the possible exception of the resistivity of the metals in the odd series of Group 5.

PERSONALIA.

Sir William J. Pope has been appointed president of the International Union for Pure and Applied Chemistry.

Sir Humphrey Rolleston has been elected president of the Röntgen Society for the session 1922–23.

To Sir Dugald Clerk has been presented the Albert Medal of the Royal Society of Arts, in recognition of his important contributions to the development of the internal-combustion engine.

Dr. W. T. David, professor of engineering in the University College of South Wales, has been appointed to the chair of civil and mechanical engineering in the University of Leeds, in succession to Prof. Goodman.

Mr. D. A. Pritchard, until recently electrochemical superintendent to the United Alkali Co. in England, is now works manager of the Canadian Salt Co., Windsor, Ontario. Mr. W. Kynoch has been appointed superintendent of the Forests Products Laboratories, and Mr. R. E. Gilmore superintendent of the Fuel Testing Laboratories of the Canadian Department of Mines.

Dr. F. G. Cottrell, lately head of the division of chemistry and chemical technology of the National Research Council, U.S.A., has been appointed director of the Fixed Nitrogen Research Laboratory of the Department of Agriculture. Dr. R. C. Tolman, the present holder of this post, has been elected professor of physical chemistry and mathematical physics in the California Institute of Technology at Pasadena.

Other appointments announced in the United States are:—Dr. F. F. Renwick, director of the Redpath Laboratory of the E. I. du Pont de Nemours Co.; Prof. G. A. Hulett, professor of physical chemistry in Princeton University, a member of the United States Academy of Science; Prof. J. M. Bell, head of the chemistry department in the University of North Carolina.

Dr. Duparc, professor of chemistry in Geneva, has accepted the invitation of the Soviet Government to organise the Russian platinum industry; and Dr. H. von Euler-Chelpin, professor of chemistry in the Stockholm "Högskola," has been appointed to a professorship in the University of Vienna, as from January 1, 1923.

Prof. A. Sieverts, of Greifswald, has been called to the chair of inorganic chemistry in the University of Frankfurt. Dr. Neuberg, director of the Kaiser-Wilhelm Biochemical Institute, has been elected ordinary professor in the Berlin Agricultural "Hochschule." Prof. P. P. von Weimarn has been appointed to the Imperial Institute for Technical Research, Ozaka, Japan, where he will equip a laboratory for research in colloid chemistry.

* * *

The deaths are announced of Jules Domergue, director of the Syndicat des Fabricants de Sucre de France since 1887; Thomas Gutler, who founded the beet-sugar industry in Utah and Idaho, U.S.A., aged 78 years; and Johann Pokorny, the sugar technologist, of Prague, at the age of 72 years.

Prof. Otto Lehmann, the discoverer of liquid crystals, and professor of physics in the Technical "Hochschule" of Karlsruhe since 1889, died on June 20 at the age of 67 years. Other deaths announced from Germany are:—Dr. F. Voigtländer, honorary professor in the University of Hamburg and director of the department of applied chemistry in the Research Office, Hamburg, aged 60 years; and Dr. A. von Wacker, director and co-founder of the Dr. A. Wacker Gesellschaft für Elektrochemische Industrie.

NEWS AND NOTES.

UNITED STATES.

Reported Disintegration of Tungsten.—In a letter published in a recent issue of *Chemical and Metallurgical Engineering*, Dr. G. L. Wendt replies to criticisms of the work by himself and C. E. Irion on the atomic disintegration of tungsten (*cf.* J., 1922, 131 R). Dr. Wendt states that the only spectrum unmistakably shown by the gases produced by the high-temperature explosion was that of helium. The background showed what seemed to be the banded spectrum of nitrogen, and the faint evidence of the strongest green line of mercury was possibly due to the backward diffusion of mercury vapour from the exhaust pump. An average of slightly more than 1 c.c. of gas was produced by exploding 0·0005 mg. of wire, and as the gas would correspond, if it is all helium, to nearly one-half the material of the wire, this should exclude the possibility that gases were adsorbed or occluded. The fact that no hydrogen lines were observed is of interest because the atomic weight of tungsten is an exact multiple of that of helium; and also because Sir E. Rutherford (*Phil. Mag*, 42, p. 809) produced hydrogen in small quantities from elements (B, N, F, Na,P) whose atomic weights were not multiples of four, but not from elements with atomic weights that are multiples of the atomic weight of helium. An account of the work is to appear in the *Journal* of the American Chemical Society.

Recent Research Work on Fertilisers.—Among the papers read before the Division of Fertiliser Chemistry at the Spring Meeting of the American Chemical Society was one on the fertilising value of sulphur by Mr. L. S. Bushnell, who quoted the results of experiments to show that increased yields of from 50 to 1000 per cent. have been obtained by using sulphur with alfalfa and other leguminous crops; that soils cultivated for several years contain relatively less sulphur than corresponding virgin soils; and that the fertilising value of ammonium sulphate and acid phosphate is sometimes due to their sulphur content and not to that of nitrogen or phosphorus.

Messrs. W. H. Waggaman and H. W. Easterwood described experiments on the applicability of the furnace process for producing phosphoric acid to run-of-mine phosphate. Much waste phosphate material, sufficiently rich in clay, can be briquetted after grinding to pass a 10-mesh sieve. Two methods of incorporating the necessary water were described, an average of 10 per cent. of water being found satisfactory when the briquettes were made under a pressure of 2500 lb. per sq inch. The possibility of using coal as a reducing agent in making such briquettes was favourably regarded, and it was stated that furnace tests were to be made to determine the applicability of the furnace process of producing phosphoric acid to the Florida and Tennessee phosphates.

Cyanamide used in certain fertiliser mixtures was stated by Mr. W. S. Landis to be rapidly converted into urea or other salts, but not into dicyanodiamide; when dicyanodiamide was intentionally added to them it disappeared on mixing.

The fertilising value of wool-scouring wastes was discussed by Dr. F. P. Veitch, who observed that the annual loss of this waste amounted to over 60,000 tons of fertiliser material containing the equivalent of 96,000 t. of kainit and 3600 t. of tankage. The 267,857 t. of unscoured wool used annually in the United States contains an average, for all grades, of 4 per cent. of potash (K_2O), 0·5 per cent. of nitrogen, and 15 per cent. of grease, both nitrogen and potash being water-soluble. "Base goods" containing 6 per cent. of water-soluble potash and 6 per cent. of nitrogen, and in excellent mechanical condition for application to the soil, have been prepared from concentrated wool-scouring wastes, and it is hoped that this important source of fertilising material will soon be available in large quantities.

AUSTRALIA.

Carbide Manufacture in Tasmania.—The Hydro-Electric Power and Metallurgical Co., which has recently changed its name to the "Carbide and Electro-Products, Ltd," has decided to increase its power consumption from 3500 to 5000 electrical h.-p., so that the annual output of its carbide factory at Electrona, Hobart, will probably be raised by at least 1000 tons. In the interest of economy crude limestone from the company's quarry at Nor'-West Bay is to be burnt on the spot instead of at the carbide factory.—(*Ind. Austr., Apr.* 27, 1922.)

Pottery Clay from Victoria.—An account of the examination of a sample of white clay from a deposit near Bendigo, in the State of Victoria, is given in a recent issue of the *Bulletin* of the Imperial Institute (XIX, 4, 1921). The clay contained about 4 per cent. of gritty matter, which had to be removed by washing, and analysis of the washed material indicated that the content of alumina was too low, and that of other metallic oxides and silica too high for the sample to be regarded as a china-clay of first-class quality. After washing, the clay would be suitable for making white permeable pottery, which can be glazed to yield a fine white earthenware. It is unsuitable for making hard porcelain, but could probably be used in conjunction with suitable felspathic and siliceous materials for producing "semi-porcelain" or impermeable stoneware. The washed clay could be mixed with grog for making second-grade refractory bricks.

FRANCE.

Industrial Notes.—*Chemical Industry.*—According to the German Press the agreement that is reported to have been made between the German dye trust and the Compagnie Nationale des Matières Colorantes et de Produits Chimiques and the negotiations between the German dye trust and the British Dyestuffs Corporation are the prelude to a vast international chemical combine to include Germany, France, Great Britain and Italy.

There is a notable improvement in the demand for chemicals, especially for products such as acetic anhydride, acetone, etc. used in making non-inflammable acetyl-cellulose films. Various improvements have been made in the methods of manufacturing cellulose products; thus the "cellophane" made by the Thaou-les-Vosges chemical factory is finding increasing use and a firm in Lyon is producing a new acetyl-cellulose silk which is claimed to be as strong and flexible as natural silk but more lustrous. The small demand for coal-tar products has led to a decline in prices, the quotation for benzene having fallen from 150 to 120—125 francs per 100 kg. and for toluene from 210—215 fr. to 190—200 fr. per 100 kg. Prices of paint products and mineral solvents, however, are tending upwards, and carbon tetrachloride now stands 20 fr. higher at 240 fr. per kg. It is expected that the price of zinc oxide will fall as the large new factory of the Société Française du Zinc at the Etang de Berre is now in operation. The fertiliser season is now over and orders for nitrate are not expected until the autumn. High prices, due to the heavy cost of transport, labour and sulphuric acid have greatly reduced the demand for superphosphate; thus the French consumption has declined from 1,200,000 metric t. in 1914, to only 660,000 t. in 1921, and the European consumption has fallen from 5 million t. in 1913 to 2 million t. in 1921. Despite the new reduction in the price of alcohol, the demand has not revived and stocks are growing rapidly; State control is proving as great a hindrance to the alcohol industry as it has to that of tobacco. The price per hectolitre of alcohol used in making products for the home market is 250 fr. and in making products for export 180 to 200 fr., so that manufacturers of drugs and perfumes find difficulty in competing in the foreign market as there is no margin for reducing costs.

GENERAL.

A Green Photographic Sensitiser.—The assistance which photography can render the scientific investigator has hitherto been somewhat limited by reason of the fact that quantitative measurements of the distribution of energy, even throughout the visible spectrum, have been vitiated by the well-known selective sensitiveness of photographic gelatino-bromide emulsions. The greatest deficiency of sensitiveness, and moreover that which has most effectively withstood all efforts to remove it, occurs in the green and greenish-yellow portions of the spectrum. The announcement of the discovery of a new green sensitiser by Dr. W. H. Mills and Sir W. J. Pope in the May issue of the *Journal of the Chemical Society* will therefore be welcomed as a step towards the realisation of a truly panchromatic sensitive emulsion. The compound, of which the "bathing" action is claimed to impart a uniform sensitiveness extending almost to the D line, is 2.*p*- dimethylaminostyrylpyridine methiodide, and results from the condensation of α-picoline methiodide with dimethylaminobenzaldehyde in alcoholic solution, in the presence of piperidine, by boiling for 5 hours. Recrystallised from methyl alcohol, it appears as bright red prisms exhibiting a blue reflex and melting at 275° C. A 1:30,000 to 1:40,000 aqueous solution constitutes the sensitising bath.

This is the first green sensitiser of which the constitution has been published; if its use does not lead to the formation of fog—an all too evident tendency of sensitising dyes—and if it can be successfully applied in conjunction with the known red sensitisers, the science of photography, as well as the science which is anxious to employ photography more and more as its unbiassed "eye," will be immensely richer for the discovery.

Hops.—A series of papers published by A. Amos in the *Journal of the Ministry of Agriculture* contains some very useful information on the cultivation of hops. The importance of adequate manuring is emphasised and schemes of typical manuring are given. The fourth paper (in the April issue) on commercial varieties of hops is of much interest to the brewer. The good and poor qualities of each variety are discussed. One of them (Tolhurst), which is evidently a favourite in some districts on account of its good cropping power, is of indifferent quality from the brewer's point of view, and its cultivation is to be discouraged.

Research in the Brewing Industry.—The research scheme of the Institute of Brewing is under the control of a representative committee of brewery directors, brewers, and agricultural and brewing scientists. There is no director of research, but special sub-committees deal with various aspects of the work in hand. Problems relating to the raw material of the fermentation industry are being investigated on sound scientific lines.

The latest report on the progress of the scheme has recently been issued by the Institute. The work of Mr. E. S. Salmon on the raising of new varieties of hops is described, and tests from the standpoint of yield, disease-resistance and brewing qualities of the hops are showing valuable results. The "nettlehead" disease, which has caused the loss of many promising varieties, is about to be investigated by Prof. V. H. Blackman; and manurial experiments have also been carried through. The drying of hops is receiving attention. A description with illustrations is given of an experimental oast designed by Mr. A. H. Burgess. The oast is not intended to be a model commercial plant, but is constructed to keep the various factors concerned in the process of drying under strict control. Prof. F. L. Pyman is continuing the difficult chemical investigation of the constituents of the hop upon which the preservative qualities depend.

The tainting of the beer stored in casks made of American oak seems to be caused by something extracted from the wood by the beer. Prof. Groom reports that micro-organisms appear to play no direct part in it, nor does the trouble lie in an unsuitable method of cutting the staves and end pieces. The possibility that there is some indirect relationship between the amount of starch in the oak and its suitability for cask-making is suggested and discussed. The time of felling the trees may also be of importance, and the help of the U.S. Forest Service in settling this point is being invited (*cf.* J., 1921, 32 R, 256 R, 370 R; 1922, 193 R).

The Ceramic Industry in China.—The Chinese ceramic industry has made little progress, despite its 2000 years of existence, and primitive kilns and methods are still used. Both the Government and the province of Kiangsi support a ceramic laboratory, but apparently no attempt has been made to develop production on a large scale. Nevertheless, the exports of ceramic products greatly exceed the imports; in 1920, 16,402 short tons was exported and 13,027 t. imported. The chief centres of the porcelain industry are at King Teh Chen, south of Kiukiang, Te Hua, near Hing Wah, and Shekwan, near Canton. Important deposits of high-grade kaolin are found in several localities but none is situated conveniently for supplying foreign markets; probably better situated deposits could be found. There are several undeveloped deposits in the province of Fukien, but the most promising is situated in the province of Kwantung, where there is no local industry but abundant labour.—(*U.S. Com. Rep.*, *Apr.* 10, 1922.)

Exports of Minerals from Tunis.—The quantities of minerals exported from Tunis in 1921 as compared with 1913 (shown in parentheses) were as follows:—Phosphates, natural, 1,455,239 metric tons (1,984,000 t.); iron ore, 204,012 t. (594,200 t.); lead ore, 5997 t. (59,446 t.); zinc ore, 7812 t. (30,627 t.). Official statistics do not record an export of lead metal in 1913, but in 1921, 15,230 t. was shipped. Of the phosphate exported in 1921, France took 576,277 t., Italy 522,012 t., Great Britain 84,377 t., and Belgium 72,565 t. The iron ore went chiefly to Great Britain, Germany and France, the lead to Spain and France, and the zinc ore to Belgium and France.—(*U.S. Com. Rep.*, *May* 8, 1922.)

Lead and Zinc in 1921.—The Imperial Mineral Resources Bureau has compiled the following advance statistics showing the world's production, imports and exports, of lead and zinc during 1921:—

LEAD.

			1921 Long tons.
United Kingdom	Imports ..	Pig and sheet	132,602
	Exports ..	Pig lead	11,098

New German Committee for the Standardisation of Non-Ferrous Metals.—The standardisation of metals and metallic alloys in Germany has hitherto been entrusted to a sub-committee of the standardisation committee for German industry as a whole, but it has now been decided to form an independent organisation to be known as the "Fachnormenauschuss für Nicht-Eisen-Metalle" (Berlin N.W.7, Sommerstrasse 4a). The expenses of the new committee will be paid by contributions from producers and consumers. The working committees on copper and copper alloys, aluminium and its alloys, lead, tin and its alloys, low-tension cables, etc. will not be affected, but a new working committee has been formed to deal with commercial analyses of non-ferrous metals.—(*Metall u. Erz*, *May* 8, 1922.)

Potash Production in the Far East.—Japan is the only Far-Eastern country that produces potash in quantity, although most Asiatic countries possess potential supplies in the form of seaweed. Thus the ash of seaweed found abundantly on the Coast of the Philippine Islands contains about 45 per cent. of potash, but it has not yet been utilised industrially. Three or four companies are engaged in the potash industry in Japan, and in 1920 they exported 1143 tons of potassium chloride in addition to 834 t. of potassium carbonate, which was shipped to the United States. The industry is worked on a small scale in China, chiefly in Kwantung province, Canton being the exporting centre; potash worth 40,000 to 50,000 taels (tael=roughly 3s. 7d.) is exported annually, mainly to Hongkong. Small quantities of potash are also exported from the Dutch East Indies and from the Straits Settlements.—(*Ch. of Comm. J.*, *May* 19, 1922.)

New Commission for the Perfumery Industry in Italy.—By a decree dated March 30 the Italian Ministry of Industry has appointed a commission composed of representatives of the Ministry and of the floricultural and perfumery industries to report on means for improving those industries.—(*G. Chim. Ind. ed App., May,* 1922.)

Production of Gums in the Red-Sea District.—In order of importance, the principal gums produced in the Red-Sea district are gum myrrh, from Abyssinia and Arabia, gum arabic, from Somaliland and Mokalla, and gum frankincense, from Somaliland, the Yemen, and the island of Socotra. Gum myrrh from Abyssinia is considered the best, but gums from the interior of Africa have to be cleaned and prepared for the export trade at Aden. Exports of these gums, almost entirely from Aden, were as follows in 1920 and 1921:—

	1920.		1921.
	Long tons.		
Gum myrrh	1057·5	..	678·6
Gum arabic	509	..	271·7
Gum frankincense ..	1440·4	..	766·1

The production of gums in Arabia has declined owing to internal unrest.—(*U.S. Com. Rep., May* 8, 1922.)

PARLIAMENTARY NEWS.

Imports of Glassware.

Answering Mr. Gilbert, Sir W. Mitchell-Thomson gave the quantity and value of the glassware imported from Germany during the year ended March 31, 1922, as follows:—Domestic and fancy glassware, including cooking utensils, table and ornamental glassware, 2718·7 tons, £105,375; illuminating glassware, globes and shades (other than oil-lamp chimneys), 1990·2 t., £73,103; other illuminating glassware (other than oil-lamp chimneys, electric-lamp bulbs and miner's lamp glasses), 21·5 t., £852.—(June 26.)

Fuel Oil.

Mr. Bridgeman informed Mr. L. Malone that the Anglo-Persian Oil Company's refinery at Llandarcy, Swansea, would be used for treating crude petroleum only. The Government did not interfere in the company's commercial activities and the use of the refinery for treating oil produced by the destructive distillation of coal would be a matter for the company and colliery interests. The increasing use of fuel oil was but a small factor among the causes of unemployment in coalfields. The development of home supplies of oil was being considered by the Fuel Research Board. —(June 26.)

Exportation of Morphine.

Mr. Shortt informed Mr. Ramsden that the export of morphine from this country was prohibited except under licence and all possible steps were taken to prevent export for other than medical or scientific purposes. As the traffic could be controlled successfully only by international co-operation, the League of Nations was urging its members to adopt and enforce a system of importation certificates at an early date.—(June 28.)

"Reparation" Duty.

Sir C. Oman asked why parcels consisting of single copies of scientific works, ordered by a private individual, passed without paying "reparation" duty if sent through the post, whereas they were charged with the full 26 per cent. levy if sent in a parcel or box through the customs department at Harwich. Sir J. Baird replied that the importation of a single copy of a book as cargo would be quite unusual, but if further information were supplied, an inquiry would be made.—(June 29.)

Answering Mr. Kiley, Sir R. Horne said that neither France, Belgium, nor Italy collected "reparation" duty on German goods, which, if sold to an independent purchaser in one of those countries, would be exempt from the levy on importation into the United Kingdom.—(July 4.)

Imports of Hollow-ware.

In reply to Mr. Gilbert, Sir W. Mitchell-Thomson said that the imports of hollow-ware from Germany during the year ended March 31, 1922, were as follows:—

	Tons.		£
Aluminium hollow-ware, domestic	1,014	..	166,775
Iron and steel hollow-ware, domestic:—			
Cast, enamelled	1,980	..	115,867
Wrought, enamelled	6,968	..	294,275

—(June 26.)

Mr. Baldwin, replying to Mr. Hogge, said it was not intended that enamelled hollow-ware imported into this country to be further enamelled should be exempt from the provisions of the draft Order.—(July 3.)

Dyestuffs (Import Prohibition) Act.

Replying to Capt. Bagley, Sir W. Mitchell-Thomson said that persons interested in importing German dyestuffs into this country had, no doubt, endeavoured to obtain from German makers price quotations that could be used as arguments for modifying the Act, but that had not been done to any great extent.—(June 28.)

Mr. Baldwin said, in reply to Mr. Hogge, that the licensing committee appointed under the Act had met 40 times; the quorum necessary for considering or refusing licences consisted of one independent member, one representative of the dye-makers and one of the dye-users.—(July 3.)

British Dyestuffs Corporation.

In answer to Mr. G. Thorne, Sir W. Mitchell-Thomson said that no reason for modifying the decision not to appoint a committee to inquire into the situation of the Corporation had arisen out of its recent annual meeting.—(June 26.)

Replying to Major Barnes, Mr. Baldwin said that the Government had power to nominate only two representatives on the Board of the Corporation. It would not be necessarily of advantage to require that no member of the board should be a director or interested in other dye or chemical companies or that at least one Government nominee should possess special knowledge of dye-making. Apart from small samples of 1 kg. each, obtained for research and experimental work, the Corporation purchased no German dyestuffs or intermediates during 1921.—(July 3.)

Exports of Perfumery.

Answering Mrs. Wintringham, Mr. Baldwin gave the following figures of exports of perfumery and perfumed spirits in 1920 and 1921:—

		1920.		1921.
Exports of home manufacture:—				
Perfumery containing spirit	lb.	963,707	..	137,945
Perfumery, other	„	4,744,241	..	1,700,422
Spirits, perfumed, in bond ..	galls.	74,518	..	15,406
Spirits, perfumed, not in bond	„	—	..	18,172
Exports of foreign and colonial manufacture:—				
Perfumery containing spirit	lb.	—	..	559
Perfumery, other	„	224,658	..	212,871
Spirits, perfumed	galls.	679	..	674

—(July 3.)

Safeguarding of Industries Act.

The following are summaries of answers given by the President of the Board of Trade to questions relating to the operation of the Act:—

Inquiries. — All committees appointed under Part II. are directed to report on the effect that the imposition of a duty would have on employment in any industry using goods that are the subject of the inquiry.—(June 26.)

Optical and Scientific Instruments.—Complaints of the difficulties in obtaining material for research take no account of the change in the cost of all commodities, and also in industrial conditions in Germany which have resulted in abnormal delay in delivery and a lower standard of quality. British manufacturers are making every effort to improve the quality and reduce the cost of their products, and it would be advantageous if men of science would co-operate sympathetically with them.—(June 26.)

The statement in the last annual report of the Medical Research Council that its operations have been greatly hampered by the high cost of scientific instruments and materials refers to the year ended September 30, 1921, when the Act was not in operation, and thus confirms the view that the increased cost of research is not due mainly, or even very appreciably, to the Act.—(July 3.)

Vulcanised Fibre.—The Committee on vulcanised fibre is not precluded from proceeding with the inquiry because of an increase in the price of the imported article, as the increase may be only temporary or intended to avoid the operation of the Act.—(July 3.)

Glassware.—The practicability of collecting the duties on glassware set out in the draft Order made under Part II of the Act has been discussed by the Board of Trade and the Board of Customs, but it is not intended to consult persons familiar with the trade. Imports of domestic and fancy glassware during the first five months of 1920, 1921, and 1922 were 1550 tons, 1451 t., and 1769 t., respectively.—(July 3, 4.)

Boric Acid.—The duty collected on imported boric acid from October 1, 1921, to June 20, 1922, amounted to £21.—(July 4.)

LEGAL INTELLIGENCE.

Contract for Supply of Explosives. *Hickson and Partners, Ltd., and Others v. The Crown.*

In the King's Bench Division on June 26, Mr. Justice Bailhache heard a petition of right against the Crown by Hickson and Partners, Ltd., of Bradford, Sharp and Mallet, Ltd., of Copley, Brotherton and Co., Ltd., of Leeds, and R. Graesser, Ltd., of Ruabon.

The suppliant companies claimed the balance of £60,000 due for TNT and picric acid supplied to the Government. When they asked for the balance of the contract price, the Crown claimed it was entitled to retain the money as a contribution, under the Munitions (Liability for Explosions) Act, 1916, to a fund for compensating damage caused by explosions to life or the property of third parties. The suppliant companies contended that such retention of moneys was not authorised by the Statute, and that the Crown had levied a contribution that was out of proportion.

After consultation, the parties arrived at a settlement on terms that were not disclosed, the Crown agreeing to pay the taxed costs of the suppliant companies.

REPORTS.

Thirty-ninth Report of the Comptroller-General of Patents, Designs, and Trade Marks, 1921. *London: H.M. Stationery Office. 1922. Price 6d.*

Although less business was done by the Patent Office in 1921 than in 1920, the amount was still above the pre-war average, except in regard to applications for registering designs. The decrease in the number of complete specifications for patents was due to the expiry of the extensions of time granted under the Peace Treaty and the Berne Agreement of 1920, but there was an increase in the number of provisional specifications. The following is a statistical summary of the work done during the past two years:—

	1921.	1920.
Patents:—		
Applications	35,132	36,672
Provisional	24,674	23,255
Complete	19,159	21,796
Sealed	17,697	14,191
Designs:—		
Applications	13,387	13,669
Registered	12,313	13,071
Trade Marks:—		
Applications	11,959	14,064
Registered	7,518	7,122
Letters, etc. dispatched	265,000	263,000
Parcels of publications dispatched	112,000	92,000
Patent specifications sold	270,707	260,368

There were 35 hearings upon oppositions to the grant of patents, and 11 appeals to the Law Officer. Of the 4278 hearings fixed under Sections 7 and 8 of the Acts, 2588 were withdrawn, and in 6 of the 1690 cases decided appeals were made to the Law Officer.

The preponderance of trade marks registered for chemical and allied products is particularly noteworthy.

The number of readers who used the library increased from 120,512 to 129,975. The new classification of the library is now complete; 6567 volumes were added to the library during the year, making the total number of works 60,347 (190,242 volumes, excluding duplicates).

Receipts from patents fees amounted to £445,947, from designs fees £9648, and from trade-marks fees £47,803. The total receipts, £525,500, represent an increase of £37,958 over 1920, and were the largest ever received in any one year. Expenditure totalled £451,912, leaving a surplus of £73,588.

Report on the Economic, Commercial and Industrial Situation of Sweden, Dated March, 1922. *By H. Kershaw, H.M. Commercial Secretary, Stockholm. Department of Overseas Trade. Pp. 60. London: H.M. Stationery Office. 1922. Price 1s. 6d.*

In spite of the apparent advantage of the high exchange-value of Swedish currency and the possession of a credit balance abroad, Sweden suffered severely from industrial depression during 1921. The timber and pulp industries were subject to fluctuating prices, poor demand, and competition from Finland. The export trade in newsprint paper was fairly good, but in other kinds unsatisfactory. In the pottery industry prices were reduced by 40—50 per cent. last autumn owing to lowering of wages and reduced costs of raw materials; competition from Germany then declined significantly. The glass industry has developed considerably. Cement manufacturers have been severely hit by the almost entire suspension of building operations, and by the acute competition from neighbouring countries. With one or two exceptions, all the manufacturers are now united in a single combine.

The greatest depression of all prevailed in the iron and steel industry, whose production in 1921 was only 30 to 40 per cent. of that before the war (cf. J., 1922, 133 R). Although the export of matches s improving and the industry is regaining its former position in foreign markets, stocks are so large that the factories must restrict output for some time. Details of the mineral output (cf. J., 1922, 36 R) for 1921 have not yet been issued, but 1,330,000 t. of iron ore was exported, mainly to Germany, and there are still large stocks. Extensions and enlargements of existing hydro-electric plants have been curtailed until costs have fallen, but new stations and extensions in course of construction will increase the total capacity from 1,200,000 to 1,500,000 effective h.-p. Much attention is being paid to industrial standardisation, especially in the engineering, electrical and woodworking industries.

British methods of trading in Sweden, it is pointed out, need improving; and there will be good openings for British chemicals, china, pottery and cut-glass when conditions improve. German competition is very severe, but defective deliveries from Germany are causing much dissatisfaction.

Report on the Economic, Financial and Industrial Conditions of the Netherlands, Dated February, 1922. *By* R. V. Laming, *H.M. Commercial Secretary, The Hague. Department of Overseas Trade. Pp.* 48. *London: H.M. Stationery Office.* 1922. *Price* 1s. 3d.

The depression in Dutch industry which marked the close of 1920 continued throughout 1921, the decline in foreign, and especially the German, exchanges and the eight-hour day Act being particularly adverse factors. In the coal industry supplies improved, but the output of 3,927,000 tons was not much larger than in 1920, and receipts did not cover costs of production. Work on new shafts was continued and a new canal system has been completed. Owing to the fall in the price of coal, production of lignite declined by 1,181,000 t. to 117,000 t., and the peat industry became stagnant. The salt mine at Winterswijk passed through a difficult period, the duty on refined salt being insufficient to protect the refineries, of which only four are working.

Agriculturally the year 1921 was satisfactory, but the area under and the yield of flax both declined. In the colonies, the agreement between the cinchona factories and the plantations was renewed. Most Dutch East-Indian plantation companies, except, perhaps, the sugar companies, passed through a difficult period and the improvement in the world's market at the end of the year probably saved many of the rubber companies from extinction. A company was formed by the Royal Dutch Petroleum Co. to develop the Djambi oilfields under Government control.

Imports during 1921 declined in value by 1,092,073,970 gulden to 2,240,353,120 gulden, and exports by 331,871,111 gulden to 1,701,491,711 gulden (gulden=1s. 8d. at par), but by weight the former increased by 3·4 and the latter by 1·5 million tons. Exports of coal, 557,400 t., bunker coal, 696,700 t., refined sugar, 159,800 t., and condensed milk, 74,000 t., increased, but those of paper, textiles, vegetable produce, and margarine (69,500 t.) decreased. There was an increase in the importation of earthenware, stone and similar products, but serious declines in metals, minerals, yarn and textiles. Imports of coal amounted to 4,894,000 t. (2,969,000 t. in 1920), the United Kingdom supplying 1,784,000 t. Increases were shown in the volume and decreases in the value of imports of vegetable oil, the raw material being most in demand. Germany took first place in the import trade with 629 mill. gulden, followed by the United States with 392 mill. g., Great Britain with 311 mill. g., and Belgium with 227 mill. g. Of the exports Great Britain took 350, Germany 254, Belgium 167, and the United States 46 mill. g.

At the date of the report trade prospects were far from hopeful. Germany was losing ground owing to delay in executing orders and to insecurity of payment. As the British exchange has remained stable and prices have decreased, the demand for British goods will improve if prices of raw materials continue to decline.

OFFICIAL TRADE INTELLIGENCE.

(*From the Board of Trade Journal for June* 29 *and July* 6.)

OPENINGS FOR BRITISH TRADE.

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence), 35, Old Queen Street, London, S.W. 1, from firms, agents or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of Firm or Agent.	Materials.	Reference Number.
Argentina	Pottery	225/6/F.G. M.C./C.
"	Sheet and plate glass	15
Australia	Chemicals, plaster, clays, etc. for the pottery industry ..	3
"	Chemical and pharmaceutical products, drugs	†
British India ..	Cement, soap, chemicals, rubber goods, dyes	8851/E.D./ G.C.
Cuba	Liquid coal-tar disinfectant ..	6257/F.L./ S.C.2
Czechoslovakia ..	Chemicals for the glass, paper and textile industries ..	721
Danzig	Chemicals for sugar-refining, machine oils and fats ..	722
Denmark	Gasworks pitch	5790/F.R./ M.C.

† Ref. No. 412/20/7/3080. Official Secretary, Commercial Bureau, Australia House, Strand, W.C.2.

TARIFF. CUSTOMS. EXCISE.

Australia.—The drawback on goods which have been imported into and undergone further manufacture in the United Kingdom may be deducted from the value declared for customs duty on re-export to Australia.

Barbados.—Customs duties have been increased by one-fifth on all dutiable imports except charcoal, edible oils, cottonseed, and kerosene.

Belgium.—From June 24, an import duty of 10 francs per hectolitre has been imposed on light oils or spirits of a density less than 0·77 at 15° C. derived from mineral oils. From June 30, aniline dyes may only be imported under licence, but do not require a certificate of origin.

Canada.—Recent modifications of the customs tariff affect various kinds of paper.

Egypt.—Consignments of fertilisers will not be admitted after August 1 unless accompanied by an official certificate of analysis.

Fiji.—It is proposed to reduce the export duty on copra from 20s. to 15s. per ton.

France.—The "co-efficients of increase" applied to the import duties on many vegetable oils, mineral and paraffin wax, aluminium sulphate, lactose, and manufactures of copper have been modified.

New Zealand.—Definitions of oils for customs purposes are given in the issue of June 29. Photographic plates are admitted duty-free under the British preferential tariff, but pay a duty of 15 per cent. *ad valorem* under the general tariff.

Poland.—The customs surtax applied to the duties on printing and other paper has been reduced.

St. Christopher and Nevis.—Recent amendments to the customs tariff affect explosives and spirits. The schedule of export duties on sugar, syrup, molasses, cotton, and coconuts has been revised.

Sierra Leone.—The importation of methylated spirits that contain less than 10 per cent. by volume of wood naphtha and 0·385 per cent. of mineral naphtha (sp. gr. 0·800) is prohibited.

TRADE NOTES.

FOREIGN.

German-Swiss Trade in Chemicals.—Official Swiss statistics of the chemical trade between Germany and Switzerland are given below:—

	1913.	1920.	1921.
		Metric tons.	
Swiss imports from Germany:			
Pharmaceutical products	2,997·3	878·3	779·7
Perfumery	64·1	91·9	52·4
Alumina	3,776·4	13,913	13,071·8
Acetic acid, crude	769·3	475·3	312 9
Methyl alcohol	1,208·7	476·1	422·9
Tar-oil derivatives	3,132·7	6,391·0	3,680·7
Dyes	6,371·9	3,369·9	2,870·2
including coal-tar dyes	669·8	495·6	362·4
Chemicals, total	84,217·7	52,522·7	34,403·8
Basic slag	47,748·7	2,054·9	9,137
Potash fertilisers	13,223	12,217·3	6,155
Swiss exports to Germany:			
Calcium carbide	25,013·2	1,736·2	1,250·2
Glue and gelatin	767·4	810·1	651·1
Chemicals, total	49,437·3	5,281·4	3,835·7

The chemicals imported from and exported to Germany by Switzerland in 1921 were valued at 17,841,000 francs and 3,896,000 fr., respectively.—(*Chem. Ind., Apr.* 24, 1922.)

German Company News.—Meister, Lucius u. Brüning, F. Bayer u. Co. and the A.-G. für Anilin-Fabrikation are paying dividends of 30 per cent. each for 1921, *i.e.*, 10 per cent. more than in 1920. The Chemische Fabrik Griesheim-Elektron has raised its dividend from 16 to 27 per cent. Meister, Lucius u. Brüning, whose capital was increased to 430 million mk. in 1921, and 470 mill. mk. in May, 1922, made a net profit of 3·45 mill. (2·74) mk. carried forward 175·80 (64·54) mill. mk. and placed 1 (3·30) mill. mk. to reserve. F. Bayer u. Co., with the same capital, made a net profit of 201·43 (102·17) mk. and carried forward 3·05 (2·49) mill. mk. (*cf.* J., 1922, 174 R).

The Vereinigte Glanzstoffabriken A.-G. in Elberfeld states that there was a strong home demand for its products throughout its past financial year, and that it did practically no export trade, in spite of very attractive foreign prices. Every effort is being made to increase production, and the reconstituted factory in Sydowsaue has already a good production. The firm's interests in Germany and abroad have been extended. The balance for the year was 50,044,132 mk. (42,977,350) out of which dividends amounting to 30 per cent. (20) have been paid, and large sums placed to reserve.

The Schering Chemical Works, Berlin, G.m.b.H., has been formed with a capital of 200,000 mk. to market the products of the Schering Co. abroad and to import and export goods.

The A.-G. Lithoponefabrikation, Berlin, has declared a dividend of 35 per cent. The brisk demand for the company's products still continues and prospects for 1922 are considered favourable.

The Sacharin-Fabrik A.-G. vorm. Fahlberg, List and Co. in Magdeburg is paying a dividend of 15 per cent. and a bonus of 10 per cent., as in the previous year. Prospects are said to be very good.

At the recent meeting of the Gesellschaft für Linde's Eismaschinen A.-G., it was decided to distribute a dividend of 25 (20) per cent., and to double the share capital.—(*Chem. Ind., Apr.* 17, 24, 1922.)

Foreign Chemical Trade of Sweden in 1920 and 1921.—The imports and exports of chemicals and related products in 1920 and 1921 were as follows:—

	1920.	1921.
	Metric tons.	
Imports:—		
Sodium nitrate	23,048·6	26,050·9
Caustic soda and potash	5,375·5	4,224·4
Potassium chloride	6,058·2	128·4
Chloride of lime	9,028·7	1,853·3
Sodium sulphate and bisulphate	50,337·6	13,453·1
Calcium nitrate	22,302·5	14,855·6
Potassium carbonate	1,909·1	693·8
Soda, sodium bicarbonate	18,783·4	8,864·4
Potash salts (Stassfurt)	49,508·2	37,625·4
Thomas phosphate	—	5,801·5
Phosphate, crude	112,853·3	70,227·8
Mineral oils	189,729·8	145,589·2
Coal tar	11,370	2,818·1
Vegetable oils and fats	17,690·3	12,196·2
Zinc white, lithopone, barytes	5,310·6	5,037·8
Vegetable tanning materials, extracts	3,589	4,007·4
Sugar, refined	29,965	6,800·6
Hides and skins, raw	11,911·5	9,945·1
Salt, domestic	26,843·4	26,765·3
Coke	358,259	235,022
Coal	2,806,303	1,458,188
Sulphur	57,659·5	21,037·9
Pyrites	114,600	58,003
Pyrites cinders	18,369	15,833·9
Iron and steel	115,351	58,065
Iron, pig and scrap	97,526	23,514
Copper, crude	18,178	6,192
Exports:—		
Calcium and barium carbides	7,897·2	6,544
Potassium and sodium chlorates	2,785·3	1,582
Calcium cyanamide	100·2	
Copper sulphate	151·6	69·7
Superphosphate	42,375·7	18,382·1
Other chemicals	1,650	1,445·5
Pulp, wood:—		
Mechanical, wet	214,210	88,590
Mechanical, dry	57,755	15,290
Sulphite cellulose, bleached	44,162	16,158
Sulphite cellulose, unbleached, wet	40,733	5,614
Sulphite cellulose, unbleached, dry	511,859	298,562
Sulphate cellulose	140,548	102,701
Cardboard, paper, etc.	284,998	183,095
Cement	68,131	28,939
Felspar	16,947	20,252
Matches, wooden	36,450	19,975
Matches, safety	34,800·4	18,519·5
Iron and steel and manufactures of	222,677	124,630

Preliminary statistics give the value of Swedish imports as 3,373,484,826 kronor in 1920, and 1,266,237,485 kr. in 1921 and of the exports as 2,293,587,083 kr. and 1,097,273,992 kr. in the two years, respectively (krona = 1s. 1½d. at par, now roughly 1s. 2d.).

REVIEWS.

Gas Chemists' Handbook. *Compiled by the Chemical Committee, Technical Section, of the American Gas Association. Second edition, March, 1922. Published by the American Gas Association. Price $6 net.*

The work under review is published by the American Gas Association for the use of chemists in gas undertakings, for whom it will form a manual of great value, containing as it does a fairly complete account of the analytical and control methods commonly used there in gas works and coke-oven installations. The different sections have been written by chemists actually engaged in the work who for the most part give a clear and well-reasoned account of the methods described and of the precautions necessary in carrying them out. For British chemists the value of parts of the book will be less than for chemists in America, as certain of the methods described are inapplicable to British conditions, partly because in the different countries the type of apparatus employed has developed on different lines (*e.g.*, in the case of gas analysis), and partly because several of the methods are of an empirical nature, in which certain specified conditions of test must be complied with, and the conditions agreed upon differ in the two countries. Nevertheless a very considerable proportion of the book will be equally useful here, and even where the methods employed differ, a study of the other methods may often be helpful in devising means of improving the tests employed here in speed or accuracy or in both respects.

The very important matter of the correct sampling of the materials tested, whether solid, liquid or gaseous, frequently so inadequately treated in books of this kind, receives extended treatment, the methods given being, for the most part, those prescribed by the American Society for Testing Materials and the Bureau of Mines. Space does not permit of an extended criticism of the methods of analysis prescribed, but in general these appear to be satisfactory, and in accordance with present knowledge. A point to be commended is the statement in connexion with many of the tests of the "tolerance" which is allowable between duplicate tests made by the same observer, and also between different observers testing the same sample.

On the other hand, certain of the methods given seem to be distinctly inferior to those used for the same purpose in this country. For example, the most unsatisfactory chapter in the book is that relating to cyanogen (possibly because very little in the way of extraction of cyanide products is carried out in American gas works). Practically the only method described for the determination of ferrocyanide is that of titration with copper sulphate according to the plan first described by Bohlig in 1862, and no mention is made of the more recent methods, such as those of Feld and Williams, in which the amount of hydrocyanic acid in the products is determined, and which are much more accurate and more easily and quickly carried out. Sulphocyanides, which are here often of considerable importance, barely receive mention, and no methods of analysis are given. The method given for the determination of naphthalene in gas by means of picric acid, appears very cumbersome and liable to considerable experimental error, and inferior to several of the modifications of the picric-acid method in use here. No mention is made of the method now in general use here of determining the amount of sulphur, excluding tarry matter, in spent oxide, by heating the extracted sulphur and tar with concentrated sulphuric acid at 100° C., which is far more preferable to the tedious and unpleasant method of treating the mixture of sulphur and tar with nitric acid and chlorate, and subsequently precipitating the sulphuric acid formed as barium sulphate.

The book is well printed and illustrated, and although, for the reasons given above, it cannot be as suitable to British as to American chemists, it will nevertheless be a valuable addition to the laboratory library in gas works and coke-oven installations in this country.

H. G. Colman.

Sewerage and Sewage Treatment. *By Harold E. Babbitt. Pp. xii.+531. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd. 1922). Price 25s. net.*

This book, as the author points out in the preface, is the development of a series of classroom and lecture notes. It would, therefore, not be fair to compare it with the many larger treatises which have been compiled on these two wide and complex subjects, but there are, nevertheless, in the text illustrations, tables, diagrams and data which will help both the student of sanitary science and the sanitary engineer.

Introducing each branch of the subject with a discourse on the pure theory and passing on to a description of the execution of the work and the finished plant (in some cases with notes of the working of the installations), the author impresses the reader with the feeling that he is well abreast of the times in his information. Since the subject of sewage treatment and disposal is one which must of necessity be regarded in the light of theory and experience combined, this academic method should appeal to the student.

Although it is not reasonable to look for a chapter on every branch of the subject in a work of this size, it will be found that the author has covered most of the ground available to him without going into too many details.

Most writers deal with the sewage problem as the result of having studied it in different countries, but the author has confined his remarks and examples exclusively to American practice, a fact which should be borne in mind by the reader since the American engineer does not invariably aim at the same goal as his brother professional in this country. For instance, quickness of construction and cheapness of production are not infrequently accepted in the States as meritorious when they would not be so accepted in England if they militated in the least degree against efficiency.

The careful study of what is being done in any one country where sanitation is taken seriously and the tale of successes, failures and general vicissitudes through which the sewage problem has passed are bound to be educative, and are interestingly told by the author to his readers.

As America is the home of the system known under the name of Dilution, one would naturally expect a sound practical reference to it, and in this the reader will not be disappointed.

The chapters on Work Preliminary to Design (of sewerage systems), Quantity of Sewage, and Pumps and Pumping Stations contain much valuable and interesting instruction and include data on construction and maintenance, on the selection and characteristics of the different makes of pumps and on general equipment, sufficient for most needs of the sanitary engineer.

Other chapters of special note to the reader are found under the headings Sedimentation of Sewage and Activated Sludge. In these the principles of the working of the Imhoff Tank and its design and treatment are dealt with fully, whilst a table of bibliographical references on activated sludge emphasises the fact that only by carefully following detailed descriptions of what has been and is being done in various places can one hope to strike a true balance of the relative merits and demerits of this method of sewage purification, which is still in its infancy.

The twenty-one chapters of this book form not only an attractive synopsis of the history of sanitation and the development of sewage purification written by the able pen of a man who has kept pace with the times, but they contain a wealth of illustrations, tables, diagrams, costs, quotations from specifications, and descriptions of execution of work.

J. D. WATSON.

THE CORROSION OF IRON. *By* DR. J. NEWTON FRIEND. *Carnegie Scholarship Memoirs. Vol. XI. Pp.* vi+161. *Published by the Iron and Steel Institute,* 28, *Victoria Street, London, S.W.* 1. 1922. *Price* 16*s.*

This is a special volume, issued by the Iron and Steel Institute as a Carnegie Memoir. It deals with the present state of knowledge on the corrosion of cast iron and steel: the protection of iron; the influence of temperature on the rate of corrosion; and the colloid theory of corrosion. This theory has been developed by Dr. Friend, and a number of new and interesting observations and experiments are recorded. The report is likely to be a standard of reference, and should be read by all interested in this subject.

We have received the subjoined correspondence relating to the review of Mr. F. F. P. Bisacre's book "Applied Calculus" which appeared in our issue for May 15.

Mr. Bisacre writes:—

"Certain questions of fact arise in connexion with the review to a few of which I should like to direct your attention. (1) The reviewer states that "In this work the conception of o—the vanishingly small infinitesimal—is developed exclusively by the method of limiting values."

The two methods by which the Calculus may be approached are both given in the book, namely, the usual method of Limits, and the method of "Infinitesimals," but "the conception of o—the vanishingly small infinitesimal"—is not developed in the book for the reason that it is an exploded doctrine of the seventeenth century. The work of Weierstrass, Cantor, Hardy, Hobson and Whitehead—to name a few pure mathematicians—has finally disposed of a doctrine that Bishop Berkeley poked fun at so successfully. The reviewer must forgive me for trying to avoid the false doctrines of the past.

(2) In the reviewer's remarks on my treatment of the exponential function, after saying that the author does so and so, he says: ". . . he proves that the derivative of e^y is e^y." The author neither *proves* nor pretends to *prove* this, in a mathematical sense. The method he has used is entirely an experimental one, which leads the reader, in a practical fashion, to discover for himself, with the aid of a book of tables, the properties of the exponential function and logarithms, and the author says this and disclaims any pretence to mathematical rigour in the following passage: "The theory of these functions is difficult, and proved a formidable stumbling-block in the history of mathematics. The theory is best worked out by methods beyond the scope of this book, and for the present we shall take the tables for granted, and endeavour to ascertain the most important properties of the functions from these tables."

(3) In criticising the method of obtaining the derivative of sin x, the reviewer has left out three essential lines of working and two references, and goes on to say: "To students who are not expected to have a knowledge of algebra beyond quadratic equations, the seeing of this equation means that they have advanced further in trigonometry than is usually taught to such." What the author actually says in the Preface as to preliminary mathematical equipment is this: "All the mathematics that the student is assumed to know is algebra up to quadratic equations; *elementary trigonometry up to the formulæ of sines, cosines and tangents of compound angles;* the elements of geometry; and the method of graphs."

(4) The reviewer writes as follows: "In the Preface the author states that infinite series are avoided altogether as being difficult and unconvincing, yet he is driven to Taylor's series; . . ." What the author says is "Infinite series are essentially difficult and unconvincing *unless treated rigorously*—as the old conundrum of Achilles and the tortoise shows—and there is no need to use them in the elementary parts of the subject." As to the reference to Taylor's series, there is not a Taylor's series in the whole book!

REVIEW

Vol. XLI] JULY 31, 1922 [No. 14

THE ANNUAL MEETING IN GLASGOW

VISIT TO THE ARDEER FACTORY OF NOBEL'S EXPLOSIVES CO., Ltd.

At the invitation of the Directors of Nobel Industries, Ltd., 100 members visited the above factory on Saturday, July 8. The party travelled by special train from St. Enoch Station, Glasgow, and on reaching Stevenston was conveyed on the company's private line to the Ardeer Factory. On behalf of Nobel Industries, Ltd., the guests were welcomed by Sir Ralph Anstruther, Lord Cochrane and Mr. Rogers, and by Mr. J. A. Cockburn, works manager of the factory.

The visitors were divided into parties, and each party was conducted through selected portions of the factory by a member of the chemical staff.

The site of this factory was selected by Alfred Nobel in 1871. On its front it faces the Firth of Clyde, and the factory covers an area considerably over a thousand acres. The guests first of all visited the boiler station, where 19 Lancashire boilers distribute steam through more than 20 miles of piping. The fuel for these boilers is entirely mechanically handled. After visiting the Power Station, where the turbo generators and air-compressors were examined, the parties entered the "danger" area and were conducted to the summit of one of the "nitroglycerin" hills, from which an extensive view of the factory was obtained. It was at once apparent—and the photograph makes this clear—that the term "factory" is rather misleading, for, instead of one building or group of allied buildings, the Ardeer works consists of hundreds of distinct and widely separated houses, many of which are surrounded by high sand-embankments.

The plant for the manufacture of nitroglycerin was briefly described, and a typical nitrating house was shown, the lead-lined nitrators in which yield one ton of nitroglycerin per charge.

The parties then descended the hill and passed through a portion of the Blasting Department. Although no more than a department at Ardeer, it is the largest blasting-explosives factory in Europe. After visiting one of the "Gelatin" houses where blasting gelatin and gelignites are made, each party was conducted to the Dynamite Huts, where an exhibit of various blasting and propellant explosives was inspected. Blasting explosives may be broadly classified in two sections: the gelatinous type and the powder type. Among the former class may be mentioned Blasting Gelatin, Gelatin Dynamite and Gelignites, whilst Samsonite No. 3 and Super Rippite No. 2 are "permitted" gelatinous explosives, *i.e.*, their use in fiery mines is sanctioned by the Home Office. It is interesting to note that, after the invention of dynamite by Nobel in 1866, he continued his researches in the hope of obtaining some substance which, while itself powerfully explosive, would dissolve in nitroglycerin and convert it into a jelly. The outcome of these investigations was the discovery of Blasting Gelatin in 1875. Among the "permitted" powder explosives may be mentioned Viking Powders Nos. 1 and 2, Thames Powder No. 2, Rex Powder, Stomonal No. 1, Super-Cliffite No. 3, and Dynobel No. 3. A very large number of blasting explosives, among which may be mentioned Quarry Monobel and Rockite, are made for ordinary and special blasting purposes.

Another interesting exhibit was that of Tonite, a compressed mixture of barium nitrate and guncotton. This explosive is manufactured for use in submarine demolition, in distress-signal work, and for blasting. Tin canisters were exhibited which contained quantities of Tonite up to 200 lb. These larger charges are prepared for submarine and special demolition purposes. A number of distress signals, which may be fired either by ordinary ignition or by percussion, were also inspected.

The next hut contained an exhibit of propellant explosives manufactured for military, naval, and sporting purposes. Cordites of all sizes, from those for the 15-inch gun to the magazine rifle and revolver, were inspected. A specially interesting exhibit was a comparatively new propellant called "Ardeer Cordite." During the last few years much research work has been carried out at Ardeer on the preparation of cordite without the use of alcohol and other volatile solvents, thereby avoiding the use of potential foodstuffs in times of national emergency. A process on these lines has now been devised whereby "Ardeer Cordite" in any size may be prepared from nitroglycerin and nitrocotton, and despatched for proof and use in a single day. This cordite possesses many desirable features, not only as regards ballistics and stability, but also from the standpoint of manufacture. Among the manufacturing advantages may be mentioned the fact that wet nitrocotton is used, thereby avoiding the dangers always incident upon the drying of nitrocottons. Nitrocellulose powders, both for field guns and rifles, were exhibited, including the special powders used in the match rifle competitions at Bisley and progressive powders for use in high-velocity military rifles. Many varieties of sporting powders of both condensed and bulk nitro types were shown. Ballistite, the standard condensed powder invented by Nobel in 1888, and the forerunner of cordite, was exhibited in various sizes both for use in small arms and ordnance. This was the propellant used for the trench mortar during the late war. The bulk nitro types of sporting powders, of which E.C., Empire and Schultze powders were shown, are characterised by the necessary charge occupying the same volume as the older, heavier charges of black powder.

Leaving the "danger" area, the parties proceeded to the Acids Department and inspected the glycerin-distillation plant, where saponification and soap-lye glycerins are distilled prior to their conversion into nitroglycerin. One of the Tentelew units, for the manufacture of oleum, was next inspected. Arsenical pyrites is used as the source of sulphur in this contact process, and this factory is the only private factory in the Kingdom where the Tentelew process is employed. Nitric acid, of concentration up to 90 per cent., is made from sodium nitrate, and the mixed sulphuric and nitric acids are subsequently employed for the manufacture of nitroglycerin and of various types of nitrocotton. A short inspection was also made of the towers used for denitrating spent acids and the concentration of weak nitric acid. Kessler plants are employed for the concentration of sulphuric acid obtained from the various refuse acids. In this department lead nitrate is manufactured for the preparation of pigments, and there is also a plant for the purification of trinitrotoluene.

Unfortunately, time did not permit of a tour round the Research Department. This section consists of extensive laboratories equipped for special purposes and is staffed by 30 chemists and physicists, together with many specially trained assistants. During the winter months classes in chemistry and closely related subjects are conducted for the benefit of the apprentices and assistants, and these classes are recognised as a part of the diploma course of the Royal Technical College, Glasgow. The department is organised so that there is always intimate contact between manufacture and research, whilst special laboratories have been erected where semi-manufacturing experiments may be carried out. The department has repeatedly worked in collaboration with Government departments, and is at present giving assistance to the committee recently appointed by the Government to consider the testing of permitted explosives. The Library, containing over eight thousand volumes, is unique among commercial libraries, and a librarian, a staff of indexers and reporters are continuously employed in the abstraction, indexing and distribution of scientific and other useful information. The majority of pure and applied scientific journals, both British and foreign, are always available. In addition, a card-indexing system was instituted some years ago and now embodies over a quarter of a million cards (*cf.* J., 1919, 37R).

A most interesting exhibition of the products of the various factories of Nobel Industries, Ltd., was inspected in one of the large rooms of the general offices. Samples were on view from the following constituent companies:—Nobel's Explosives Co., Ltd.; Kynoch, Ltd.; Curtis's & Harvey, Ltd.; Lighting Trades, Ltd.; Necol Industrial Collodions, Ltd.; Eley Bros., Ltd.; British Pluviusin Co. (1920), Ltd.

After this inspection the guests were entertained to lunch. Sir Ralph Anstruther presided, and at the conclusion proposed the toast of the Society of Chemical Industry, to which Dr. E. F. Armstrong, in the unavoidable absence of the President, Dr. R. F. Ruttan, replied.

After lunch the visitors proceeded to the Testing Station and inspected the apparatus for testing blasting explosives. The firing pit, consisting of a large steel autoclave buried in sand and used for firing explosives at a loading density comparable with that employed in mines, was first examined. The apparatus is arranged so that samples of the gases, evolved on explosion, may be easily withdrawn and analysed. Two ballistic mortars used for determining the strength of explosives were then shown; one of these is an exact replica of that used by the Home Office for testing the strength of permitted explosives. An apparatus for determining the length and duration of flame of blasting explosives was examined and several photographs illustrating the flames obtained with various types of blasting explosives were exhibited. In the calorimeter room a selection of calorimeters for use in measuring the heat evolved on exploding both blasting and propellant explosives was seen. The Bichel pressure-gauges used to measure the pressure developed by explosives when detonating were inspected, together with typical charts obtained in this test. This apparatus consists of a strong steel cylinder resting on a concrete foundation. The charge to be tested is placed in the chamber on a small wirework tripod and fitted with an electric detonator fuse, of which the wires are carried through the walls of the cylinder. The explosive chamber is closed by means of a strong steel cover and the air in the chamber may be exhausted. Vertically above the test charge is an adjustable valve-attachment, and a pencil

THE ARDEER FACTORY OF NOBEL'S EXPLOSIVES CO., LTD.

or stylo is adapted diagrammatically to mark a rotary drum set in motion by a motor. In the same room, the Fall Hammer Apparatus used for determining the sensitiveness to shock of various explosives was exhibited. The next apparatus examined was the Mettegang Recorder used for determining the rate of detonation of explosives, and the method of working of the apparatus was portrayed diagrammatically. The action of this recorder is purely electrical, so that errors of observation are eliminated to a great extent.

The visitors then passed through the engineering and instrument-makers' workshop, where much of the finer apparatus used in the examination of explosives is made, and proceeded to an experimental press house erected solely for studying the phenomena underlying the pressing of gelatinised propellant explosives. The climatic magazines were pointed out, where experimental explosives are stored in hot dry and in hot, moist atmospheres and their stability under these storage conditions examined. These magazines are constructed so that the regulation and measurement of temperature are entirely automatic. Further, the explosive samples are stored in separate fire-proof cells, so that the decomposition and ignition of one sample cannot be communicated to the samples in the adjacent cells.

The last inspection was that of the Safety Explosives Gallery. This gallery is an exact replica of the Home Office Gallery at Rotherham, where the Government testing of proposed "permitted" explosives is carried out. The test consists of finding the maximum charge of the explosive which fails to ignite both a sensitive mixture of coal gas and air and a mixture of coal dust and air. Testing is continued until the maximum charge is found which does not ignite these mixtures for five successive shots. This maximum charge is called the "charge-limit" of the explosive and in fiery mines not more than this quantity is allowed to be used in one borehole.

DEMONSTRATIONS

Preliminary experiments were carried out to show the various methods of firing explosives and the difference between burning and detonation. The difference between explosion depending on rapid burning and explosion due to detonation was illustrated by firing gunpowder by safety-fuse alone and dynamite by a detonator fired by safety-fuse and by a detonator fired electrically. The difference between burning and detonating the same explosive was effectively displayed by igniting a cartridge of Cambrite No. 2 by a flame and a similar cartridge of the same explosive detonated by a No. 6 detonator.

The carrying out of the following tests was then demonstrated :—

(*a*) *The Lead Block Test*, in which a definite weight of explosive is fired in a cavity in a lead cylinder and the increase in volume of the cavity measured. This increase gives a rough indication of the shattering power of the explosive.

(*b*) *The Ballistic Mortar Test*, in which the explosive is contained in a cavity in the side of a steel mortar which forms the bob of a large pendulum. The shot is tamped by a steel block which forms a sliding fit in the first block. When the shot is fired the magnitude of the recoil of this large pendulum gives a measure of the heaving effect of the explosive.

(*c*) *The A.D.C. Test* for determining the maximum length of air-gap through which explosion can be transmitted from one cartridge to another.

(*d*) *The Velocity of Detonation Test*: by the D'Autriche method. This method is not an absolute method such as that in which the Mettegang recorder is employed. TNT fuse, a thin lead tube containing a core of compressed trinitrotoluene, is employed in this test and the results obtained depend on the rate and uniformity of detonation of this fuse.

(*e*) *Safety Explosives Gallery Test*: Shots were fired showing the ignition of coal-gas – air mixtures and of coal-dust – air mixtures by means of explosives.

The guests were then assembled in order to observe a demonstration of some of the properties and practical applications of explosives. The first experiment, in which a cartridge of Blasting Gelatin was placed (*a*) a little distance above an iron plate, (*b*) in contact with a plate, and (*c*) "tamped" or confined on a plate, illustrated the effect of "tamping" an explosive. The last method is much used for cutting steel plate in the destruction of old ships. The next experiment illustrated a typical application of explosives in the removal of obstacles. A row of cartridges was laid close up to the foot of a wooden palisade and confined by a banking of earth. A single shot served to remove completely the whole of the palisade. An example of the application of explosives in modern agriculture was illustrated by constructing a trench by a single detonation. In the next experiment a large cast-iron ring, weighing over 3 tons, was satisfactorily broken up for the scrap-iron heap by the application of a "plastic" shot to the inner face of the portion of the ring in contact with the ground. As a companion experiment a large iron pot, weighing over 5 tons, filled with water, was completely demolished by a single explosive charge fired under the water. In this case the application of a "plastic" shot would be unsatisfactory, owing to the shape of the pot and the danger that would be incurred from flying metal. A series of distress and sound signals was next discharged. Distress signals are very complicated in design, but consist, essentially, of a charge of gunpowder for propelling the signal from the firing socket into the air, a charge of colour composition, which is expelled away from the main charge by a small compressed gunpowder charge, and a main charge of Tonite which is detonated by means of a time-fuse and detonator. Sound signals are used in lighthouses during foggy weather. They consist of a charge of compressed Tonite and are inserted in a revolving-wheel device which detonates them at regular intervals by means of a detonator inserted in them. The last experiment illustrated the use of explosives in labour-saving by the demolition of a chimney stack. Owing to the proximity of the stack to other buildings, it had to be brought down in a definite direction. Bricks were removed from the base of the stack, leaving supporting pillars on that side of the stack towards which it was required to fall. These pillars were then bored and charged with the requisite weight of explosive.

The thanks of the Society are due to Sir Harry McGowan and the Directors of Nobel Industries, Ltd., for their hospitality; to the members of the Chemical Staff who acted as guides and interpreters; and, not least, to Dr. H. Hepworth for supplying the above account of the visit.

CATALYSIS THROUGH AMERICAN SPECTACLES

E. F. ARMSTRONG and T. P. HILDITCH

THE Committee on Contact Catalysis of the Division of Chemistry and Chemical Technology of the American National Research Council has published its first report, written by the Chairman, Prof. W. D. Bancroft, in the form of a serial story appearing in the pages of the *Journal of Industrial and Engineering Chemistry* (April-July, 1922).

The subject is surveyed thoroughly and incisively, the views of the upholders of various theories are given exhaustively and illustrated by well-chosen extracts from their published papers, and the report is enlivened by considerable humour—a mode of treatment which may be recommended to the discreet attention of most writers of scientific literature. The Committee states that it seemed the best thing it could do in its first report was to outline, as clearly as possible, the present situation in regard to contact catalysis. After that, it should be a relatively simple matter to determine what to do next. One rather gathers that the result has been to discover objections to all the theories of contact catalysis at present in the field, so that "what to do next" should resolve itself into the establishment of a really satisfactory sound explanation, pleasing alike to physical chemists of all schools and also, let us hope, to the mere chemist.

The "radiation" hypothesis fares worst: the paucity of experimental evidence, or, rather, the apparent indifference of its exponents to the desirability of experimentally, as well as hypothetically, correlating infra-red absorption with catalytic action in as many cases as possible, is stressed, and the conclusion reached is that "it is quite extraordinary that a theory like this should get a scientific standing with apparently nothing back of it." It is, however, in regard to the treatment of the other two hypotheses—"intermediate compound" and "adsorption"—that we are tempted to join issue with the Committee, which seems very impossible to please: but perhaps destructive criticism is so easy.

The present writers' disavowal of precise knowledge of most of the "unstable intermediate compounds" (in the transient existence of which they have been led to believe from a consideration of the chemical transformations in hand) is quoted *in extenso*, including the statement that they might well be as "indefinite" as the adsorption of dye by fibre,[1] and is followed by the criticism that though we believe firmly in the formation of definite intermediate compounds, our conception of an intermediate compound is so elastic and our knowledge of the compositions of the assumed intermediate compounds is so limited that there would probably be no difficulty in re-writing all our results in terms of adsorption.

Yet, when the latter view is considered in detail, it receives somewhat rough handling: "If we adopt Langmuir's views of oriented adsorption, all sorts of things become possible"—but "such a suggestion is of very little value unless it can be made definite . . . it may well be that some entirely different hypothesis will prove necessary . . . for the moment it looks as though the organic chemist were the safer man to follow . . . the identification of the intermediate compounds does not account for the catalytic action. On the other hand, it is impossible to take the next step until the intermediate compounds have been identified." This, in sporting language, looks like backing each theory both ways; at the same time the Committee concludes that the difference between what is meant by those who talk of "definite" or "indefinite intermediate compounds," and those who refer to "adsorption" is "psychological and not chemical."

The possibility of explaining catalysis by means of the kinetic theory of molecular collisions—the function of a catalyst being then in some way to increase the opportunities for collisions of molecules, perhaps in specific positions, is considered in some detail, but the Committee is apparently inclined to the view that on the whole "activation by adsorption" affords a better explanation. The vagueness of what is implied by "activation" is fully appreciated by the Committee, as may be seen from its reference to Baly's hypothesis on "opening up fields of force," but it seems to feel that Langmuir's theory of "oriented adsorption " offers the possibility of an explanation of the supposed activation, for the last word is a suggestion that Langmuir's theory would throw more light on the real problem of contact catalysis if it were developed so as to show, for example, that an ester was adsorbed in different ways by different catalytic agents, and that the reaction took place at the point of the molecule " where the ester tied on to the adsorbent, forming the indefinite compound."

---

[1] Proc. Roy. Soc., 1920, **98A**, 37

Whether this is psychological or etymological difference, it is perfectly plain that the Committee's final conclusion, the Langmuir theory of adsorption, in so far as it applies to catalysis, and our own intermediate-compound theory, all come to the same thing. Frankly, we are tiring of etymological splitting of hairs in this matter. Organic chemists will always regard these things from their own standpoint, and so will physical chemists or pure physicists; but what we maintain is that in recent work on catalysis the " adsorption " school of physicists and the " intermediate-compound " group of organic chemists have developed theories which are on closely converging lines, and we suggest that the next move is a definite acceptance of this fact by both sides, followed by mutual exchange of views to facilitate further progress. If the organic chemist, for example, were to state frankly the details which do not at the moment fit in closely with his point of view, and mutual examination of temporarily irreconcilable data were undertaken by representatives of the chemical and physical views from their respective standpoints, it is more likely that progress would be resumed than if the apparently interminable discussion on terminology were pursued further.

The reluctance of some chemists (we had almost written catalytic chemists) to have anything to do with chemical compounds, however unstable, is hard to understand, but is well illustrated by the Committee's failure to grasp why, if the dehydration of alcohol by alumina depends on the intermediate formation of aluminium ethylate, kaolin should act almost as well as alumina, since " the formation of a definite kaolin ethylate seems improbable." Now, surely it is common knowledge that kaolin and the many other complex silicates and alumino-silicates, although definite in one sense, are indefinite in that various molecular proportions of the constituent oxides may be found combined together and *may act to some extent independently of the total molecule as such.* Thus, in some other complex silicates, the zeolites, it is actually and readily possible to replace some of the bases by others, for example, soda by lime, and *vice versa*, without affecting in any way the alumino-silicate part of the complex. Since then the complex silicate molecule is so flexible that part of it can be chemically interchanged without disrupting the whole, it is equally possible for the alumina in kaolin to carry on transient combination with alcohol without affecting the rest of the kaolin molecule. The phenomenon of base-exchange in the zeolites is a particularly beautiful analogy of the ease of intra-molecular chemical interaction which, although non-catalytic, should be borne in mind before dismissing too lightly the probability of intermediate-compound formation during catalysis.

The action of " promoters " is dealt with briefly in the report, reference being made to Pease and Taylor's summary of the data on this branch of the subject.[2] Whilst quoting Rideal and Taylor's supposition that the promoter alters the proportion in which the interactants are adsorbed at the catalyst surface, the Committee adds an alternative suggestion, namely, that perhaps the catalytic agent activates only one of the reacting substances or activates one chiefly, whilst the promoter activates or increases the activity of the other. The subject of promoter action is, however, so complicated and obscure that a considerable amount of further detailed experimental work is necessary before a general explanation is likely to be discovered. It is shown that the theory of poisoning of contact catalytic agents has been more satisfactorily developed. Any substance which retards, or prevents, the approach of the reacting substances to the catalytic agent will slow down or put an end to the reaction; or, the poisoning of a catalytic agent is due to marked adsorption, which cuts down the adsorption of the reacting substances.

The recent work of Taylor and Burns,[3] of Maxted,[4] and of others is fully discussed and the evidence for the above views concisely summarised. An interesting point is made when it is remarked that " poisoning " of non-catalytic reactions is a familiar phenomenon in the non-corrosion of many oxidisable metals due to a minute protective film of oxide. In this connexion we would draw attention to the unfortunate manner in which physico-chemical theory lags behind technical practice in the realm of catalytic action. It is no secret that, as in other technical applications of catalysis, the matter of " poisons " was one of the greatest difficulties connected with fat-hydrogenation. These difficulties were overcome in works' practice ten years ago mainly by consideration of the possibility of " films " of various kinds preventing contact between catalyst, oil and hydrogen, although the blessed word " adsorption " was not specifically invoked, even though it had by that time been invented.

Rosenmund's[5] employment of suitable " poisons " to modify the action of catalysts is referred to, and this seems to be a field of which the potentialities are by no means yet fully explained.

[5] Ber., 1921, 54B, 435, 638, 1092

Other subjects which are dealt with are the mixed oxidation catalysts devised by Lamb, Bray and Frazer,[6] Rideal's attempted connexion between overvoltage and catalytic power,[7] and the apparent stimulation of some catalytic hydrogenations by small quantities of oxygen.[8]

Whilst the report gives a very full account of the present knowledge of the procedure of contact catalysis, we feel that the lines on which further work is apparently recommended to be undertaken are somewhat restricted in scope. In our opinion more attention should be paid to the characteristic side actions which proceed during most cases of catalysis.

Although we have handled the report critically, we do not wish in any way to detract from its great value at the present juncture. The more fully and frankly such problems are discussed the better for chemical progress; all hypotheses are of value provided they are put to the test of experiment and even in catalysis an ounce of practice is worth a great deal of theory. The thanks of all chemists are due to Prof. Bancroft and his colleagues for the labour they have expended on their report.

ASSOCIATION OF BRITISH CHEMICAL MANUFACTURERS

THE sixth annual report of the Association covers the most difficult period, from the trade point of view, which has yet been experienced; but, despite the adverse circumstances, the Association has firmly maintained its numerical strength, improved its finances, and established its position.

For the first time in the history of the Industry a thoroughly representative chemical exhibition was organised by the Association as a section of the British Industries Fair, held at the White City early in 1922. The exhibition created great interest, both in trade and official circles, about fifty members of the Association participated, and although, as was to be expected, they were not overwhelmed with orders, a certain amount of business was done; the real value of the exhibition lay in the education of the public mind as to the scope and possibilities inherent in British chemical industry.

The revision of the Association's Directory has proved to be more complicated and difficult than was anticipated. The Russian and Japanese languages have been replaced by German, and the lists of products and proprietary trade names have been extended. The publication should be ready for distribution at an early date. During the year the Association's pamphlet on "British Research Chemicals" was revised and greatly enlarged to cover about 1800 fine-chemical products, including inorganic chemicals, indicators, and microscopic stains; many thousand copies were distributed to chemists, Trade Commissioners and others interested, in all parts of the world. Information concerning the industry has been contributed to the Press throughout the year, and the public has been kept informed of the progress of the industry.

The Council, having felt that the time had come when an effort should be made to get the terms of contracts with public authorities so amended as to be just and reasonable to both the contracting parties, approached the Federation of British Industries, and this body has set up a committee for the purpose of revising the conditions of forms of contract, tender and specifications in use by Government departments, municipalities and other public bodies. Mr. H. Ferguson represents the Association on this Committee.

Since the conclusion of the war many countries have revised their customs tariffs, and those of Spain and the United States have in particular engaged the attention of the Council. Mr. R. G. Perry has represented the Association on the advisory board nominated by the Federation of British Industries to assist the Board of Trade in its negotiations with the Spanish Government.

Much useful work has been carried out by the Joint Research Committee of the Association and the British Chemical Plant Manufacturers' Association, and an understanding has been reached with the British Engineering Standards Association whereby overlapping of activities will be avoided; the latter Association has issued a Directory, which supplies a long-felt want. The report on the Standardisation of Steam-Jacketed Pans (*cf.* J., 1922, 52 R) aroused great interest throughout the industry, and its excellence is shown by the adoption of the specification by the British Engineering Standards Association as the official British standard. A similar report on standard covers for jacketed pans will be issued shortly. Preliminary reports on the standardisation of cast-iron filter-presses have been issued for criticism (*cf.* J., 1921, 401 R, 1922, 210 R), and the final report is nearly ready for publication. The use of nickel, Monel metal and chromium steel in chemical plant has been investigated.

The Association has taken a sympathetic interest in the inauguration of the Institution of Chemical Engineers, of which the General Manager is vice-chairman. This new organisation should be of considerable benefit both to chemical and plant manufacturers.

Throughout the year the Council has been constantly engaged on the problem of transport. The Railways Bill, which received the Royal Assent in August, 1921, is of great importance to the chemical industry in that, for the first time in the history of railways, it takes away from the railway companies the power of finally deciding what are dangerous goods and invests it in the Railway Rates Tribunal. Further, the rates charged on dangerous goods are in future to be subject to analysis in precisely the same manner as the rates for ordinary merchandise, so that chemical manufacturers will not have to pay for services which are not provided, as hitherto.

Apart from the Railways Act, the Traffic Committee has been fully occupied in dealing with the consequent revision of the General Railway Classification of Goods. Many objections were sent in by various members to the proposals of the railway companies in connexion with the classification of non-dangerous goods, and as the result of meetings held with the companies a number of concessions were obtained (*cf.* J., 1922, 73 R). It was, therefore, only necessary to ask the Rates Advisory Committee to adjudicate upon 20 cases, with the result that decisions favourable to members were given in no less than 15 cases. It is fair to say that no other industry received more concessions than were obtained for the chemical industry.

The classification of dangerous goods has entailed much detailed work by the Traffic Committee, as that body formed the nucleus of the Dangerous Goods Sub-Committee of the Traders' Co-ordinating Committee. The proposals of the railway companies consisted of 49 foolscap pages of printed matter, and some 150 objections were lodged. The Committee has held meetings with the railway companies extending over six days, and the result is that the Rates Advisory Committee will only be called upon to adjudicate in about 30 cases. The work of the Association, through its Traffic Committee, will lead to a very substantial saving in the cost of rail transport when the new rates and charges come into operation.

The railway companies have recently submitted their new general conditions of carriage for the approval of the Railway Rates Tribunal, and these proposals are being carefully examined in conjunction with other traders' organisations, in order that the interests of members may be fully protected. The Council has associated itself with the Federation of British Industries in opposing the Bill presented to Parliament by the North-Western and Midland and West Scottish Group of Railways asking for powers to enable the group to become carriers by road.

In December, 1920, the Home Office circulated a draft of proposed new regulations for factories and workshops. The original draft was severely criticised by members of the Association. The Council took the matter up and, after protracted negotiations, secured the issue of an amended draft, in which all the points raised by the Association were given the fullest consideration.

The Council has also considered the bearing of the following Parliamentary measures upon the interests of chemical manufacturers:—Rating of Machinery Bill, Salmon and Freshwater Fisheries No. 2 Bill, Alkali Works and Registration Acts 1906, Safeguarding of Industries Act, and the Dyestuffs (Import Regulation) Act. In connexion with the last-named, a committee has been appointed to inquire what action, if any, the Council can take to promote co-operation among the interests involved, so as to cheapen the cost of dye production in this country.

THE ANNUAL MEETING

The sixth annual general meeting was held in Burlington House, London, W., on July 13.

Sir John Brunner, Bart., presided, and in moving the adoption of the Report said:—The Association is to be highly congratulated upon the fact that it has secured the services of Mr. Woolcock upon mutually satisfactory terms for a further period of five years. Mr. Woolcock is, to a very large extent, the Association, and we cannot do without him.

There is acute difference of opinion in this country whether a tariff is good for our country or whether it is not; but I think we are all agreed that a tariff in a foreign country is not a good policy, and, unfortunately, since the war all the countries of Europe have set up almost prohibitive tariffs which have done a great deal of mischief in retarding the revival of trade. A new proposal has been presented to the United States Senate, not only with regard to tariffs, but with regard to subsidising the American shipping industry, and I am very pleased to see in the Press that they have found very great difficulty in carrying this almost prohibitive Fordney Bill, and that apparently the whole matter is again going to be dropped, as it was last year. We will, I am sure, keep our eyes upon this matter, and if anything can be done by the Council to mitigate the operation of the American tariff, I am certain the Association will do it.

In the matter of transport we are greatly indebted to Mr. Malacrida and his department. You will have seen in the papers this morning that the railway rates in this country are shortly to be reduced to 75 per cent. above pre-war figures, instead of 100 per cent., and the flat-rate increases are to be reduced from 1s. to 6d., from 9d. to 4d., and from 6d. to 4d. per ton, the flat rate of 3d. being unaffected. The rate for small parcels is to be reduced from 150 per cent. to 100 per cent. I would like to bring to your notice a sentence in the Report which says: "The constant bringing together of industrialists and railway officials has created a new atmosphere, and the relations between them are now on a very satisfactory footing," which is, I think, a great deal more than can be said of the relations of traders and railway companies in the past. It says a great deal for the tact of our officials who have been able to create this friendly feeling with the railway companies. It not only saves traders a great deal of expense but also the railway companies, and if both sides get what they want without expense it always tends to the reduction of rates.

With regard to the Home Office Regulations under the heading "Dangerous and Unhealthy Industries," a term which I personally object to, because there are a great many chemical operations which are no more dangerous to health or to life than working in a cotton factory or even sitting at a desk in the Home Office, I think it is begging the question to call the whole of the chemical industry a dangerous and unhealthy industry. It is one of the difficulties under which legislation of the present day labours that Parliament is so overwhelmed with work that regulations of this character have to be left to the various Departments. However, we have succeeded in this instance in arriving at an agreement with the Home Office which, although it is not entirely satisfactory to us, is one in which we can acquiesce, and one which has practically entailed no expense to the chemical industry of the country.

I think you can be very highly congratulated upon the continued usefulness of this Association to the trade of chemical manufacturers in this country, and so long as the members of the Council continue to work in entire harmony, that state of things will persist. In founding this Association I think that we have done a great stroke of work for the chemical industry, and I trust it will be as prosperous in the future as it has been in the past.

The motion for the adoption of the Report was seconded by Mr. Max Muspratt (vice-chairman).

In the subsequent discussion Dr. E. F. Armstrong said that the subjects of tariffs, licences, and of the whole mechanism of safeguarding industries were extremely complex but unfortunately brought in politics. Those who believed that any other policy than that of Free Trade led to destruction had been able in the case of the chemical industries to sacrifice that view for the greater end of establishing the chemical industries of this country. The heavy chemical industry had, fortunately, perhaps partly for geographical reasons, been able to stand on its own. The dyestuff and fine-chemical industries had found themselves in a more difficult position. To have an industry of that type there must be trained technical men to carry out the work. The most brilliant finance, the most original and remarkable organisation, and even cheap transport were all unavailing in the absence of technical ability, but he felt sure that such ability was plentiful in this country. The chemical industries were of national importance, not only for the products they gave and which surely should be made in this country rather than be brought from abroad, but as training grounds for chemists, the chemist being regarded as a very important servant of the State. If they reviewed the technical men holding more or less responsible positions throughout British industry, ignoring those who were connected with the heavy chemical industry, they would find a great many came out of one or two industrial schools, possibly out of the laboratories of a firm like Nobel's, and the necessity of having such industrial schools was obvious. Unless we established our fine-chemical industry and our dye industry we should have no industrial schools in which to train those chemists who would be at hand in the hour of need, whether in peace or in war.

Mr. E. V. Evans said he thought they must face the fact that the Dyestuffs Act did not afford the measure of protection that the industry really required. That Act was designed to promote the dye industry without prejudice to the textile industry, a matter which Euclid would have shown to be entirely absurd. They would remember that in order to assure that the interests of the textile industry should not be adversely influenced during the growth of the British dye industry, the Act provided that the representatives of the users should be in a majority on the Licensing Committee. The users had not taken undue advantage of their numerical superiority, but the fact was that they possessed this potentiality. Were it not that they were men honestly desiring the dye industry to be harboured in this country, the position would be an impossible one. The question of price was at the moment acute. The position was that if a consumer of dyes could show that he had to pay more than three times the amount for his British dye than he paid for his foreign dye before the war, that was sufficient justification for the importation of the foreign dyestuffs, provided, of course, that the foreign dyestuff was itself sold at a figure which was not more than three times the pre-war foreign price. This factor of three was an exceedingly serious matter to the dye industry at the present moment. He could well understand that some simple colours could be made at this price, but he was certain that the whole dye business could not be worked on that basis, and it was even more impossible to imagine that new ventures could be undertaken with this price factor in operation. It would be a totally different thing if the sales of the dye industry and the output of plant were normal. They had been forced to the conclusion that the best way to resuscitate business in this country was to labour temporarily under this disability; although their representatives had fought strenuously against the acceptance of the price factor, they had been forced to accept it for the present.

Dr. Seligman referred to the work of the Joint Research Committee of the Association and the British Chemical Plant Manufacturers' Association, of which he is chairman. He said that there had been a tendency in the past to standardise everything, irrespective of whether it was amenable to standardisation or not, and the Committee had put the brake on where it was felt desirable, and had probably contributed to more practical results in that way. The Joint Committee had before it a suggestion that it should undertake an investigation into the education of engineers for chemical works. Many members of the Committee hesitated to accept that task. They were not unanimous on the subject, and he thought if it were possible for some of the leading members of the Association to express their views whether it was desirable that the Committee should deal with this subject, it would be a great help to the Committee in reaching a decision. The whole question bristled with knotty points, and many were frankly afraid of it. Members of both the Committee and the Sub-Committees, which it had formed, had worked extremely hard, but he felt that they wanted a little more inspiration than they were getting. If only the members of the Association could give them more problems to tackle, more things which they could look into in a preliminary way, he would feel happy about the future utility of the Joint Committee.

Sir William Pearce said he was afraid that neither the nation nor the House of Commons really realised the enormous importance of synthetic organic chemistry and the great future before it in dyes and fine chemicals. He supposed they would be suspect if they went in for propaganda, but outside and inside the House of Commons the importance of these two branches of their industry was really not properly recognised, and it was a question of education. The dyestuff and fine-chemical industries would be the two great industrial successes of the future, and no nation could afford to do without them. If that view were instilled into the minds of the public and of Parliament the two industries could be secured. The Germans took that view. He had had a remarkable interview with one of the directors of the German "I.G.," who told him that the German Government and people regarded synthetic organic chemistry as the best asset they possessed and the best hope they had of recovering commercial prosperity or supremacy. That was not realised in this country. It would be a good thing if the Council could put the facts of the progress of these industries before the public. It would be welcomed by the members of the House of Commons, very few of whom really understood the great importance of those two industries. They complained to him of lack of information; they did not know the progress of these industries or understand the difficulties, which were stupendous to-day, because not only had they the enormous combination of the German I.G. to contend against, but they had to meet an unexampled slump in the textile trade.

The Rt. Hon. J. W. Wilson said he thought that one of the most important pieces of work during the year was that done at the British Industries Fair. He thoroughly agreed that they had a good deal to learn from Grmany both in unifying interests in different chemical manufactures and in educating the public and, indirectly, the buyers. He was satisfied from what he saw of the Fair that it did a great deal of good in educating the public and in bringing the members and staffs of the various chemical firms and manufacturers together to compare notes and realise that more could be gained by interchange of views than by following the traditional British attitude of looking suspect on everybody who asked a question. He thought there was a great deal more to be done by cultivating friendly relations between buyer and seller than in artificial or temporary barriers and hindrances.

The resolution was adopted and Messrs. Feasey and Co. were reappointed auditors for the ensuing year. Mr. T. Miller-Jones presented the report of the scrutineers, which was received and adopted.

A special general meeting of the Association then followed, at which the Chairman moved and Sir W. Pearce seconded a resolution to reduce the amount of the annual subscription payable by members by 20 per cent. for the year 1922–23. This was carried unanimously.

The meeting terminated with a vote of thanks to Sir John Brunner for his services as chairman during the past two years.

SAFEGUARDING OF INDUSTRIES ACT

SODIUM HYPOSULPHITE "R"

On July 7 and 8 Mr. Cyril Atkinson heard the complaint of R. W. Greeff and Co., Ltd., that "sodium hyposulphite R" had been improperly classified among the articles dutiable under Part I. of the Act. The United Alkali Co., Ltd., and the Board of Trade opposed the complaint.

In his opening speech, Mr. K. Swan, counsel for the complainants, detailed the uses of sodium thiosulphate and then referred to the counter-statement of the Board of Trade, according to which this substance is no longer made from alkali waste but by the action of sulphur dioxide on sodium sulphide, and by boiling sodium sulphite solution with sulphur. None of these processes can be described as fine-chemical. The Board intended "sodium hyposulphite R" to include the substance used for photographic and analytical purposes, which is undoubtedly a fine chemical, being made by fine-chemical manufacturers and classified as such by the Association of British Chemical Manufacturers. The "commercial" quality is less pure and is sold at prices about 50 per cent. lower than those of the "R" quality.

Mr. Swan said his case was that the methods of manufacture were not fine-chemical methods; sodium thiosulphate was used only in negligible quantities as an analytical reagent; it was a well-recognised heavy chemical and made by heavy-chemical manufacturers; the purest qualities were used for industrial purposes (chiefly photography and tanning); and that it was not an analytical reagent within the meaning of the Act. Most of the material consumed in this country came from abroad and was marketed in 1—10 ton lots. He contended that the degree of purity of a substance could not determine its classification as "fine" or "heavy," and that the Board of Trade was not justified in affixing "R" to an admittedly heavy chemical. The "pea" crystals of "hypo" used in photography were not purer than the "commercial" quality.

Evidence for the complainants was given by five trade witnesses, all of whom maintained that there was no appreciable difference in quality between the pea crystals and the larger crystals known as "commercial," and that the difference in price (about £3—£4 per ton) was mainly accounted for by the different methods of packing. Importation, which was large before the war, had practically ceased since the Act came into force.

In reply to Sir Arthur Colefax (counsel for the United Alkali Co.), who adduced prices of £12 10s. and £18 a ton for the two grades quoted in a trade journal for May 5, 1922, Mr. A. H. Gilbert, a chemical dealer, said that price quotations in all the trade papers were most erratic. It was only extreme folly which made purchasers pay the higher price for what was substantially the same article. A great deal of the "hypo" he had sold came from Germany. The term "hypo, photographic" was not recognised by dealers.

Mr. A. F. Butler, director of R. W. Greeff and Co., also affirmed that sodium thiosulphate was regarded by the trade as a heavy chemical. In his firm's price-list it was classified both under "technical" and "photographic" chemicals. When both forms (pea and large crystals) were packed in the same manner, the difference in price was only about 12s. 6d. per ton. Asked by Sir A. Colefax why "sodium hyposulphite, Rhodia brand," was priced in his firm's list of January, 1922, at 20s. per cwt., and classified, not under "Technical Chemicals" but under "Fine Chemicals and Pharmaceutical Products," witness said that Rhodia crystals were a special brand; the list was the only one issued to heavy-chemical manufacturers at the present time, and it contained other heavy chemicals, *e.g.*, oxalic and citric acids.

Mr. R. J. Kindon, of Chas. Zimmermann and Co., (Photographic), Ltd., quoted trade journals in which "hypo" was referred to as a heavy chemical. For about 20 years his firm had sold the "Agfa" brand, which was made by the A.-G. für Anilinfabrikation, of Berlin. The qualities demanded of photographic "hypo" did not include very great purity, but great whiteness, clearness, regularity of size of crystals, and freedom from dust.

Mr. O. F. C. Bromfield, secretary of the British Chemical Trade Association, said that he compiled the London market reports in the *Chemical Trade Journal*, and he contributed market news to the *Chemist and Druggist*, but in the latter case he was not responsible for the classification adopted. He had only been connected with the chemical trade since 1919, and he obtained his information from merchants, not from manufacturers. The classification he adopted was based on trade custom, and he regarded the terms "industrial" and "heavy" as substantially synonymous, and also the terms "fine" and "pharmaceutical."

Mr. E. J. Parry said that the pea crystals and the large crystals were practically identical in chemical composition; he had never seen a sample of "commercial" hypo of less than 98·5 per cent. purity, and the average difference in purity between the two forms was about 0·5 per cent. There was a third form, purified by repeated crystallisation, which was sold at about 2s. 3d. per lb., but it was quite a rarity; its use as an analytical reagent was foolish, because the "commercial" form was as good as the best for that purpose. Its use for analytical work was so small (a small fraction of 1 per cent. of the entire consumption) as to be negligible. Sir A. Colefax mentioned analyses covering 12 years, supplied by the United Alkali Co., and showing that the purity of the commercial quality varied from 93·79 to 97·46 per cent. Mr. Parry said that English manufacturers produced an article analysing 98 to 99 per cent. He admitted that sodium thiosulphate was an analytical reagent in common use and that many important industrial analyses depended upon it. In common with many other photographic chemicals, it was not a fine chemical. The Continental fine-chemical manufacturers who made and sold it, probably did so to keep their trade in photographic chemicals together.

Mr. Whitehead, for the Board of Trade, said that "hypo" of photographic quality was a perfectly well-known commodity. Before the Act came into force, the pea quality was the photographic quality, and would still be if properly and genuinely prepared; but it was now being imported in an impure state, in order to avoid duty.

Sir A. Colefax argued that the words in the Act "analytical reagents, all other fine chemicals," implied that all analytical reagents were fine chemicals. The use in photography of an admittedly heavy chemical justified its classification as a fine chemical, because it was of the definite degree of purity demanded for that purpose. Those who sold the pea quality for photographic purposes were impressed by the necessity for special tests. But there was no need to discuss the claims of "hypo" to be regarded as a fine chemical because it was admitted that the pea quality was a typical, well-known and widely-used analytical reagent.

Mr. E. B. Cook, managing director of Johnson and Sons, Manufacturing Chemists, Ltd., said that his firm sold practically only the fine pea form and the cubic crystals, both of photographic quality. These crystals were clear, of good colour (not yellow), free from moisture, and always analysed over 99 per cent., usually 99·5 per cent. and upwards; any material below 99 per cent. was rejected.

Mr. Swan expressed the opinion that "analytical reagents" meant those analytical reagents which were fine chemicals. Mr. Whitehead said that the view of the Board of Trade was that every analytical reagent was a fine chemical.

The Referee's award, signed on July 17, was as follows:—

Sodium hyposulphite is put on the market in two forms and under two descriptions. There is the ordinary quality known as commercial, which is in the form of large crystals of different shapes and sizes. There is no standard of purity or colour to which it is expected to conform. There is also the quality known as "pea crystals." The material is in the form of small crystals uniform in shape and size. Again there is no fixed standard of purity or colour to which it must conform, but it is expected to be clear, dry, and a very good white. In practice analysis shows that the percentage of purity varies from 99 to 99·5 per cent. At times even a higher degree of purity is obtained. The material is very largely used in photography, and the demand for this purpose has led to the introduction of the description "photographic quality." That description implies that the material is of the highest quality put on the market. To answer that description the material must be in the small crystal form, of very good colour, dry, and of a purity not less than 99 per cent.

There is no dispute but that sodium hyposulphite is an analytical reagent. It is in common use. It would find a place in any list of analytical reagents. The quality used for this purpose is the best obtainable, *i.e.*, the photographic quality.

Sodium hyposulphite has been included in the list published by the Board of Trade with the letter "R" against it, meaning thereby that only the highest quality, viz., the photographic quality, is to be dutiable under the Act. This inclusion in the list is justified by the Board of Trade on the ground that sodium hyposulphite of photographic quality is (1) an analytical reagent and/or (2) a fine chemical.

The complainants concede that it is an analytical reagent, but deny that it is a fine chemical. They contend that as a matter of construction the words in the Schedule only include such analytical reagents as are fine chemicals. They rely strongly on the word "other" in the Schedule. The relevant words to be construed are "synthetic organic chemicals, analytical reagents, all other fine chemicals."

I do not see how the complainants can be right. To hold that synthetic chemicals and analytical reagents are in the Schedule only if they are fine chemicals, quite apart from their claims to that description as being synthetic in the one case or analytical reagents in the other, would be to give no effect to the words preceding "all other fine chemicals."

Some weight must be given to the word "other," and in my opinion the interpretation which gives effect to all the words used is this:—The Legislature intended to protect the fine chemical industry, but the expression "fine chemical" was very vague. It was without any definite meaning. The Legislature deliberately avoided attempting to define fine chemical, but it intended that there should be no mistake about the inclusion within that phrase of synthetic organic chemicals and analytical reagents. The specific inclusion of these chemicals indicates in my opinion that the words "fine chemicals" were intended to be used in a sense wide enough to cover the classes mentioned. Parliament was content to leave the further application of the expression "fine chemicals" to the Board of Trade, and to a Referee, but their hands were to be tied in respect of such chemicals as could with reasonable certainty be described as synthetic organic chemicals or analytical reagents.

As this view seems to me the right one I thought it unnecessary to determine whether or not sodium hyposulphite was a fine chemical independently of its being an analytical reagent.

In my opinion, once it is conceded that sodium hyposulphite is an analytical reagent in regular use, the complainants' case falls to the ground, and I have no option but to award that the substance in question in its purest form is rightly included in the list as an analytical reagent. Only the purest form of the chemical is within the Schedule. It is only that form which is used as a chemical reagent.

I think that it is advisable to be a little more definite as to what is meant by the letter "R" in this particular case. It is stated on behalf of the Board of Trade that only the quality known as "photographic" is intended to be included, and I think that it would be wiser to state that in the list.

I wish it to be clearly understood that the mere fact that sodium hyposulphite is in pea-crystal form does not prove that it is of photographic quality. In my opinion photographic quality indicates that the chemical is in the form of small uniform crystals, that it has great purity of colour, and is of 99 per cent. (or thereabouts) purity and upwards. No objection is offered by the Board to the addition of the words "photographic quality."

I therefore award that the list be amended by inserting after the words "sodium hyposulphite" the words "photographic quality." The complaint fails. No order as to costs.

PERSONALIA

Dr. J. C. Drummond has been appointed to the chair of biochemistry at University College, London.

Mr. Max Muspratt has succeeded Sir John Brunner as chairman of the Association of British Chemical Manufacturers.

The honorary degree of D.Sc. of the University of Oxford has been conferred on Prof. J. Perrin of Paris and on Prof. F. Gowland Hopkins of Cambridge.

Mr. S. Pexton has been elected to the gas research fellowship founded by the Institution of Gas Engineers, and Mr. W. H. B. Hall, of the South Metropolitan Gas Co., to the Corbett Woodall Scholarship, both tenable at the University of Leeds.

The Commissioners of the Exhibition of 1851 have awarded a Senior Studentship to Mr. J. S. Buck, research student in chemistry, Liverpool; and on their nomination Mr. D. F. Stedman, University of British Columbia, and Mr. J. C. Smith, University of New Zealand, have been awarded Science Research Scholarships (Overseas) for physical chemistry and chemistry, respectively.

Dr. Lennart Smith has been appointed professor of chemistry in the University of Lund, Sweden.

Mr. L. M. Tolman, chief chemist to Wilson and Co., Chicago, has been elected president of the American Oil Chemists' Society.

Prof. A. Pictet, professor of chemistry in the University of Geneva, has been elected a corresponding member of the French Academy of Sciences.

Prof. C. H. Warren, professor of mineralogy in the Massachusetts Institute of Technology, is to succeed Mr. Russell H. Chittenton as director of the Sheffield Scientific School.

Mr. H. G. Tanner, chief chemist at the Experimental Potash Plant, Summerland, Cal., U.S.A., has been appointed to a professorship of chemistry in the University of Oregon.

Dr. Max Volmer, extraordinary professor in the University of Hamburg, has been appointed ordinary professor of chemistry in the Berlin Technical *Hochschule*. Professor M. Volmer has been appointed professor of physical chemistry and director of the Institute of Physical Chemistry in Berlin. Doctors A. Gutbier and R. Stoermer have been appointed to the chairs of chemistry in the Universities of Jena and Rostock, respectively.

NEWS AND NOTES

UNITED STATES

The Sequestrated German Patents

President Harding has ordered the Alien Property Custodian to demand the return of the sequestrated German patents that were sold to the Chemical Foundation, Inc. The demand, which affects 4000 patents and other property, is said to be based on the ground that the German patents were sold at prices insufficient to protect the interests of the former German owners for whom the Alien Property Custodian acts as trustee. The patents were sold in 1919 to the Chemical Foundation for $250,000, but their value is problematical, as the policy of the Foundation has been to issue non-exclusive licences for working them; and it is also said that less than 2 per cent. of them had been found of use. Mr. Francis P. Garvan, president of the Foundation, stated in an interview that the action was taken without giving any notice to the United States organic-chemical industry or to the Chemical Foundation, and was begun, so he was informed, after the representatives of the German "Interessengemeinschaft" and the German Government, but not American interests, had been heard by the United States Attorney-General. It is stated that the demand will be refused and the issue decided in the District of Columbia Court.—(*Oil, Paint and Drug Rep., July* 10, 1922.)

Lethal Gases for Exterminating Pests

Experiments on the use of poison gases for exterminating obnoxious birds, rodents and insects are to be undertaken in the autumn by the U.S. Chemical Warfare Service and the Biological Survey. Chlorine, when handled properly, has already given good results against "pocket gophers" and ground squirrels, and phosgene has been used successfully against rats in Porto Rico. The effects of various gases on the insect pests of growing plants and stored grain have been tested, but a substitute for hydrogen cyanide or carbon bisulphide has not yet been found.

Stone in 1919

The U.S. Geological Survey states that about 65,539,000 short tons of stone was sold in the United States in 1919, or 4 per cent. less than in 1918 and 22 per cent. less than in 1917. A total of 21,315,300 t. of limestone and marble was sold as furnace flux, 1,060,741 t. of ganister (quartzite), mica schist and dolomite as refractory stone, and 4,370,936 t. for other industrial uses. The industrial consumption of limestone was as follows:—Alkali works, 2,215,660 t.; sugar factories, 503,835 t.; glass factories, 166,106 t.; paper mills, 92,421 t.; agriculture, 1,392,914 t. In addition, 864,441 t. of limestone was sold as a filler for asphalt, paint, rubber, soap, for making basic magnesium carbonate, to alcohol and calcium-carbide factories, and for making refractories.

FRANCE

Industrial Notes

Chemical Industry.—The chemical market is firm and the demand for sulphuric acid and for fertilisers is brisk. The price of sodium nitrate tends to rise, but that of ammonium sulphate has declined to 90—92 fr. per 100 kg. There is a keen demand for cyanamide, owing to the fall in price, and most of the cyanamide factories will be occupied for some weeks ahead. Prices of turpentine oil remain firm but may increase as there is a good demand from London and supplies are not coming from the United States. The demand for synthetic perfumes has improved slightly, but the prohibitive prices of the natural products are not conducive to business. The weather remains favourable for the next sugar-beet crop, which is estimated at 500,000 t., *i.e.*, 200,000 t. more than last year's crop.

CANADA

Production of Chemicals

According to a return of the Dominion Bureau of Statistics the production of chemicals and allied products in Canada for the years 1919–20–21 was valued as follows:—$94,000,000, $118,000,000 and less than $76,000,000. The following is a summary of the principal statistics for the three years:—

	1919	1920	1921
Plants	425	450	442
Capital	$109,268,000	$116,056,000	$106,525,000
Employees	14,946	16,526	12,139
Salaries and wages	15,948,000	21,148,000	15,463,000
Cost of materials	47,216,000	58,754,000	35,148,000

Platinum, etc. in Northern Ontario

There has recently been discovered at Shebandowan Lake, Northern Ontario, an interesting occurrence of a nickel-copper-cobalt mineral relatively rich in the metals of the platinum group. The above lake is situated 70 miles west of Port Arthur, Ont., and five miles north of the Canadian Northern Railway. Some of the massive ore carries 8 to 12 per cent. of nickel, and the average rocky material, not hand-sorted, about 6 per cent. nickel, copper and cobalt. The analysis of a sample submitted to the Geological Survey, Ottawa, gave 16 oz. of platinum metals to the ton, and iron, 24·8%; nickel, 3·3%; copper, 5·5%; and sulphur, 20·6%.

Pulp and Paper

The Belgian Industrial Co. at Shawinigan, Que., is extending its paper mill at a cost of $1,500,000 to $2,000,000, exclusive of the cost of machinery.

The plant of Kaministiquia Pulp and Paper Co., at Port Arthur, Ont., has been sold to the Consolidated Water Power and Paper Co. of Wisconsin Rapids, Wisconsin. The mill makes ground woodpulp.

Production has been started by the International Paper Co. at its new plant located at Three Rivers, Quebec. When in full operation the plant will have a daily output of 384 tons of paper.

Construction upon the large pulp and paper mills at Prince George, Northern British Columbia, was due to begin in June. Initially the capacity will be 150 tons daily, but provision is being made to increase the output. The company, to be known as the Bathurst Co., Ltd., has an initial capitalisation of $3,000,000. Over 200 sq. miles of timber land have been secured east of Prince George, on the Fraser River. The promoters of the company include Lord Beaverbrook, Sir Chas. Gordon, Montreal, Mr. Frank Jones, president of the Canadian Cement Co., Peck Bros., Pennsylvania, and others. Angus McLean, of Bathurst, N.B., is president.

Metallurgical Industries

Nickel.—The mines and smelter of the International Nickel Co., at Copper Cliff, Ont., which have been closed down for many months, will be started not later than September 1. The sales of nickel by this company last year were less than in any year since 1904. The new plant at New Hunnington, W. Va., will cost $3,400,000, inclusive of equipment. The company's plant at Port Colborne, Ont., has restarted operations. Orders have been coming in freely and stock on hand is being depleted. One million pounds of nickel will ultimately be refined monthly. The smelter at Sudbury, Ont., is expected to recommence operations this autumn.

The largest shipment of nickel matte ever forwarded from Northern Ontario was recently sent to the Mond Nickel Co., at Clydach, S. Wales, from its works at Coniston, Ont. The shipment exceeded 1000 tons and the matte contained about 55 per cent. nickel and 45 per cent. copper.

The British America Nickel Corporation, Deschenes, Que., has a large stock of refined metals on hand, and it is questionable if this refinery will operate on any extensive scale this year. The British Government is holder of £3,000,000 "A" income bonds of this concern.

Iron and Steel.—There is a very marked improvement among the factories engaged in the manufacture of iron and steel and their products. A few months ago the majority of these works were working at less than 25 per cent. capacity, but to-day some are in full operation and others are working at half capacity. It is expected that another extension will soon be made to the plant of Baldwin's, Ltd., Toronto, which manufactures tin and galvanised plates. Two mills have been installed since January, making a total of five now in operation. The construction of the $20,000,000 steel plant at Ojibway, near Windsor, Ont., is being pushed with greater activity.

The plant of the Electric Steel and Metals, Ltd., at Welland, has been sold to a United States organisation. This plant, which was erected at the beginning of the war to make munitions, has been standing idle since this remunerative business ceased. The new management proposes to convert the plant into a steel rolling mill.

BRITISH INDIA

Forecast of Winter Oilseed Crops

The final general memorandum forecasts the winter-oilseed crops for 1921–22 as follows:—Linseed: acreage 2,993,000, yield 434,000 tons; rape and mustard: acreage 6,104,000, yield 1,142,000 t. Compared with the estimates of the previous year the linseed crop shows an increase in yield of 61 per cent. and the rape and mustard crop an increase of 33 per cent.—(*Ind. Tr. J., June* 8, 1922.)

GENERAL

The Federal Council

The hon. treasurer of the Federal Council for Pure and Applied Chemistry notifies that the Council has appointed a committee to raise funds for the expenses of the meeting of the International Union to be held in Cambridge next summer, and for the general purposes of the Council, including a nucleus for a fund to provide better accommodation for the various chemical societies. The committee consists of Sir William Pope, Dr. E. F. Armstrong, Mr. E. V. Evans, Dr. S. Miall, Mr. Emile Mond, and Mr. W. J. U. Woolcock.

New Photographic Desensitisers

World-wide interest was aroused by the announcement some two years ago that Phenosafranine, and its slightly more soluble homologue Tolusafranine, could be successfully employed in dilute aqueous solution as desensitisers, their action being so effective as to allow of panchromatic gelatinobromide emulsions being developed in bright orange light—or even by candle light—without the production of light fog. Both the above-mentioned safranines, however, exhibit an undesirable affinity for animal membranes—a property which led to pronounced staining of the sensitive surface of photographic plates. Somewhat protracted washing was necessary to remove the stain; in fact, the difficulty of removing the dye from emulsion coated on a film base practically ruled the dyes out of court. Research has naturally been directed, therefore, to the discovery of efficient colourless, or at least non-staining, desensitisers, and a gratifying measure of success has attended the work of Dr. E. König, of the Höchst Farbwerke, who has lately (Phot. Rund., 1922, **59**, 89; B. J. Phot., 1922, **69**, 351) introduced two products, *Pinakryptol*, a mixture of a colourless compound with a small proportion of the green dye issued in the pure state as *Pinakryptol Green*.

The colourless component of Pinakryptol is relatively insoluble, a 1:5000 aqueous solution of the mixture being difficult to prepare. If such a solution—of a muddy green colour—be allowed to act for 1½ to 2 minutes, it reduces the sensitiveness of a modern super-speed emulsion to approximately 1-1100th of its original value. As a general desensitiser it thus rivals phenosafranine, showing even more pronounced desensitising powers on orthochromatic or panchromatic emulsions, and, were it not for the drawback that marked alterations in the speed of action of various developers result from the bathing, Pinakryptol would be a most useful desensitiser. Its velocity of action during the desensitisation is not as high as is desirable, and it does not lend itself, therefore, to the method of application in which it is combined with the developing solution, except under "stand" or "tank" development conditions.

Pinakryptol Green, in spite of its strong family resemblance to the basic dyes, is practically devoid of affinity for gelatin, and, because of its relative ease of solution—a 1:500 stock solution being readily prepared in the cold—it is to be preferred to Pinakryptol. A 1:5000 solution desensitises in one minute, giving a reduction, in the case of super-speed emulsions, to a value of 1-1500th that of the original sensitiveness. The depression of sensitiveness to the longer wave-lengths is remarkably great, and the green colour of the solution, mechanically retained by the film after the bathing operation, allows of the fogless development of the most highly sensitive panchromatic emulsions, in the comfort of a bright yellow-orange light.

Very slight disturbance of the characteristics of the various developers occurs in the presence of Pinakryptol Green; and since, as is also the case with Pinakryptol, no destruction of the latent image occurs when this desensitiser is used, an extended application of the process, particularly by panchromatic workers, may be confidently anticipated.

The Colour Users' Association

The report for the year ended April 30 states that the membership is now 240 and that it represents 90 per cent. of the colour consumption of the country. Colours imported under the Peace Treaty are now selected by the Association in co-operation with the Board of Trade and are reserved for purchase by members for 14 days after arrival. By personal applications to the Board of Trade, the Vigilance Committee has secured the removal of certain chemicals from the Schedule to the Safeguarding of Industries Act. The membership had been classified into twelve trade groups, each group comprising members having common interests. Receipts during the year amounted to £3336, and disbursements to £2765, and there is a balance of £6620 in the bank derived mainly from commissions paid by the Central Importing Agency on sales of the Association's stock.

Carbonic Oxide in Tobacco Smoke

Prof. H. E. Armstrong, who is reported to sympathise with the view of King James I that tobacco "is the lively image and pattern of hell," has recently been investigating the carbonic-oxide content of tobacco smoke and the results of his "little experimental excursion" in the laboratories of the South Metropolitan Gas Co. are given in the issue of the *British Medical Journal* for June 24.

Four sorts of tobacco were smoked in a pipe or as cigarettes, which were attached to a gas-sampling bottle from which mercury was allowed to run out in "puffs," and the smoke was found to contain from 4·24 to 10·15 per cent. of carbonic oxide; the smoke from a cigar treated similarly contained 5·8 per cent., but the ratio of carbon dioxide to monoxide was much higher in the latter case. Determinations were then made by Gautier's method, viz., by estimating the monoxide by passing the purified gas over heated iodine pentoxide and titrating the liberated iodine. The percentage of carbonic oxide was found to vary between 0·6 and 0·875 in cigarette smoke, and between 0·7 and 1·14 in pipe smoke. Rapid smoking considerably increased the content of carbonic oxide.

Prof. Armstrong then resorted to natural smoking—by deputy—the fume from cigars of various qualities and ages being expelled from the mouth into a mercury receiver and then analysed. Under these conditions the average content of carbonic oxide was 4·7 per cent., compared with 2·6 per cent. in smoke obtained by mercury suction, and the ratio of carbon dioxide to monoxide was much lower. The results were little affected by make or quality; closeness of packing and rate of smoking appeared to be the determining factors. Although South Metropolitan gas was found to contain as much carbonic oxide as the smoke of an average cigar, it is not suggested that the one is an economical, or even a hygienic, substitute for the other.

What is a Chemical Engineer?

The Provisional Committee of the Institution of Chemical Engineers has provided a solution of this well-known problem. "The chemical engineer is a professional man experienced in the design, construction and operation of plant in which materials undergo chemical or physical change." This definition is commendably short, but is it sufficiently precise? Are those who design, construct and operate mining-plant or kitchen-ranges chemical engineers? Is conveying machinery within their province? And does "man" in this case include woman?

Artificial Silk in Italy

There are now five artificial-silk factories in Italy, and their total output is about 8 metric tons (? per day). All these plants are in Northern Italy, but a company which owns a factory in Venetia with a capacity of 2 tons, is erecting one new works in Rome and another in Naples. The viscose process of manufacture has entirely supplanted the expensive and dangerous alcohol process, and the necessary wood-pulp is imported from Norway. Whereas imports were formerly considerable, the Italian factories are now well able to meet any normal increase in the home demand, as well as to export considerable amounts. In 1921 the export was 588·8 t., of which 173·9 t. was shipped to the United States.—(*U.S. Com. Rep., May* 15, 1922.)

New Salt Deposit in Holland

Borings for minerals conducted on behalf of the State have revealed the presence of a deposit of salt at Corle, near Winterswijk. Previous borings in the same district had shown the existence of a deposit at great depths, but it was irregular and discontinuous. The new deposit was struck at a moderate depth—a point of great importance for eventual exploitation. The new deposit is very regular, and it is hoped that potash salts may also be found.—(*Chem. Ind., May* 29, 1922.)

The German Potash Industry

According to a report of the general meeting of the Burbach potash group, conditions in the potash industry improved considerably during the past year and sales during the first five months amounted to 561,000 tons of potash (K_2O), an increase of 60 per cent. over sales in the same period of the previous year. Sales of manufactured salts showed the largest increment, but the demand for crude salts was only moderate. Many potash works are now (June, 1922) unable to fill current orders for manufactured products, the demand having been stimulated by the liberal discounts granted to agriculture by the Potash Syndicate and the introduction of special railway rates. These increased summer sales will probably lead to still bigger sales in the autumn. So far it has been possible to keep inland prices low by charging higher export prices, and the attempt of the Government to levy a special tax on the receipts from exports is regarded as dangerous, for such a tax would inevitably result in an increase in inland prices.—(*Deutsche Bergwerks-Z., June* 23, 1922.)

Wages in the German Chemical Industry

Labour in the German chemical industry is classified under three heads, viz., general workers, technical workers (including laboratory workers, constructional engineers, chemists, and pharmacists), and office workers, each group being organised under a trade union. Of the 350,000 employees in the German chemical industry, 90 per cent. belongs to trade unions. Wages per hour paid to general workers in the Berlin district (where the highest rates prevail) at the end of 1921 were as follows:—Factory hands 8·50 mk., transport workers 8·96 mk. to 9·35 mk., boiler men and machinists 8·65 to 9 mk., labourers 8·70 to 9·10 mk., coppersmiths 9·30 mk.; apprentices 1·50 to 4 mk. The minimum rates are 33 per cent. less than those paid in the Berlin area. In addition, a family allowance of 14·4 mk. per week is made for dependents of the workers.

The average monthly wages of untrained technical workers at the end of 1921 varied from 1092 mk. in the Leipzig district to 1310 mk. in the Berlin district, and workers with technical education but no practical training were paid from 1495 mk. (Berlin) to 1890 mk. (Cologne), trained technical workers from 1650 mk. (Bavaria) to 2542 mk. (Cologne), and managers, industrial engineers from 2084 mk. (Posen, Silesia) to 2600 mk. (Berlin). The agreement controlling the labour conditions of technical and office workers in the Berlin district provides that employees shall be paid according to length of service at rates reaching a maximum in the eleventh year, that the working week shall be 46 hrs., that employees, when ill, shall be paid for 6 weeks and, after 8 years' service, for 13 weeks. A supplement of 100 mk. per month is paid for each dependent of the worker. The working hours per week vary from 45 in Central Germany to 46 in Bavaria and 48 in Leipzig (*cf.* J., 1922, 26 R).

In May, 1922, wages throughout the chemical industry were increased by 75 to 80 per cent. over those holding in January, in order to compensate for the depreciated value of the mark, and on May 26 the employers and unions agreed to fix wages during June at an average of 23 mk. per hr., 184 mk. per day, 1058 mk. per week, or 4585 mk. per month, the family bonus remaining unaltered. This represents an increase of 100 per cent., but it provides only an approximate evaluation of the wages now paid to each class of workers, as it is not known whether the increase has been evenly distributed among technical, office, and general workers.—(*U.S. Com. Rep., June* 19, 1922.)

Sugar Production in Czechoslovakia

It is estimated that the sugar-beet crop for the season 1921–22 was 3,475,000 metric tons, and that the yield of raw sugar was 640,000 t., of which 560,000 t. has been refined to white sugar. In 1920-21 the beet crop was 4,200,340 t., and the production of sugar 717,240 t. During the six months ended March 31, 1922, the consumption was 168,835 t. and exports 257,141 t., leaving 262,364 t. on hand at April 1, 1922. Trade in sugar is now unrestricted, but Government control of profits is continued because of the difference between the home and foreign prices. Prices of raw and refined sugar were fixed at 338 and 650 kronen per 100 kg., respectively, during the 1921–22 season, as compared with 79 kr. in 1914-15 (kr. = 10d. at par, now about 1·1d.).—(*U.S. Com. Rep., May* 22, 1922.)

Copper in 1921

The following statistics have been compiled by the Imperial Mineral Resources Bureau:—

			Long tons
United Kingdom	Imports	Bars, blocks, etc.	84,320
	Exports	Bars, blocks, etc.	10,885
Northern Rhodesia	Production	Finished copper	196
Southern Rhodesia	Production	Blister copper	2,750
	Exports	Bar, blister and ingots	3,016
Union of S. Africa	Production		141
		Metal content	92
	Imports	Bar, rod, ingot	20
	Exports	Ore and regulus	183
South-West Africa Protectorate	Production	Copper, lead-ore	72,643
	Exports	Copper-matte	1,414
Canada	Production		23,867
	Imports	Ore and concentrates	1,228
		Blocks, pigs or ingots	413
	Exports	Fine copper in ore, etc.	4,692
		Blister copper	14,767
		Pigs, bars, sheets, etc.	1,453
India	Imports	Unwrought copper	504
	Exports		77
Australia	Production		10,971
		Refined copper produced in Australia, and metal in blister, matte, ore, etc., exported	18,634
	Exports	Refined copper	12,082
		Copper in blister, matte, ore, etc.	34
Belgium	Imports		15,296
France	Imports	Ore and concentrates	6,459
		Cement, crude, ingots, anodes	48,029
	Exports	Ore and concentrates	1,492
		Cement, crude, ingots, anodes	3,779
Italy	Production	Ore	22,300
		Metal	97
Norway	Exports	Ore	561
		Crude and refined	1,016
Russia	Production	Ore	4,600
Belgian Congo	Production		29,978
Madagascar	Exports	Copper	4

PARLIAMENTARY NEWS

House of Commons

British Dyestuffs Corporation

Mr. Baldwin, replying to Major Barnes, said he was aware of the financial position of the Corporation, but no proposals had been made respecting the Government's holding in it.—(July 10.)

Sales of Coal to Germany

In answer to Lieut.-Com. Kenworthy, Mr. Bridgeman stated he had no information that British coal sold to Germany was being transferred to France as "reparation" coal. During the first half of 1922, 6,616,992 tons of British coal was exported to France and 2,882,655 t. to Germany.—(July 12.)

Applications for Patents

Sir W. Mitchell-Thomson informed Capt. W. Benn that the delay in dealing with applications for patents was largely due to arrears of work caused by war conditions and depletion of staff for military service. Since the war the number of applications had increased to an average of 35,000 yearly, as compared with 30,000 in 1913. Every effort was being made to return to normal conditions.—(July 14.)

Norwegian Cement

Replying to Mr. J. Wilson, Mr. Baldwin stated that the prices quoted during 1921 for bulk consignments of British cement were slightly below the average declared value of imported Norwegian cement. The price of British cement and the average value of imported Norwegian cement had both fallen during the present year, but continued to approximate closely. The Board of Trade had no power to ensure the continued consignment of Norwegian cement to this country.—(July 17.)

Railway Rates

In answer to Mr. Gilbert, Mr. Neal said that the railway companies in England and Wales had announced general reductions in railway rates for goods traffic from August 1. The rates were not fixed for any definite period, but the Federation of British Industries and the companies had agreed not to apply for a general alteration to come into force before July 31, 1923.—(July 17.)

Export Duties in African Colonies

Answering various questions, Mr. Churchill said that the duty on palm oil exported from Sierra Leone had been reduced to 20s. 10d. per ton, which was a little more than 4 per cent. of the price at Freetown at the end of May. Recently the export duties on palm oil and palm kernels in Dahomey were 49·5 francs. and 24·75 fr. per metric ton, respectively, the corresponding rates in Nigeria being £3 and £2 per ton and in Sierra Leone 20s. 10d. and £1 per ton. The export tax imposed on cotton from Uganda was designed to raise revenue for developing the cotton-growing districts; since the tax was applied the export had increased from 6300 tons in 1919 to 14,500 t. in 1921. The reason why it had not paid to export hides and skins from Nigeria was the fall in value of the hides from 1s. 3d. to 5d. or 6d. per lb. and not the export duty, which had been reduced from 2d. to ½d. per lb.

The export duty on cocoa in the Gold Coast had not prevented a continuous increase in the shipments of cocoa, but the possibility of a reduction would be considered.—(July 17, 18.)

Smoke Abatement Bill

Sir A. Mond informed Mr. Betterton that he hoped to introduce the Smoke Abatement Bill at an early date.—(July 18.)

Cocaine

In reply to Mr. Lyle, Mr. Shortt said that no cocaine was produced in this country and that no statistics of consumption or trade were kept.—(July 18.)

Measuring Instruments Bill

A Bill to extend the powers of the Board of Trade, to make regulations with respect to measuring instruments used for trade, and to amend the law with respect to instruments used in ascertaining wages, and for purposes connected therewith, was presented by Sir W. Mitchell-Thomson and read a first time on July 19.

Safeguarding of Industries Act

Refund of Duty.—A motion, moved by Mr. Kiley, to insert a new clause in the Finance Bill providing for the repayment of duty collected on scheduled articles that have afterwards been removed from the lists, was rejected by 208 to 95 votes. Sir R. Horne observed that the Act specifically excluded the possibility of claims for refund of duty, and in any case it would be impossible to discover the person who in the end had paid the duty, as the article was usually sold before the inquiry was held.—(July 12.)

The following are summaries of answers given by the President of the Board of Trade to questions relating to the operation of the Act:—

Dumping.—Since Part II came into force in August, 1921, less than 120 trades or branches of trades have communicated with the Board of Trade. Of 45 complaints relating to goods made in Germany, 13 were referred to committees; in 29 cases complainants failed to establish a *primâ facie* case or withdrew the complaints, or have been asked to supply further information; and 3 complaints are now being considered.—(July 10.)

Glass Bottles.—The Board of Trade is aware that, at the inquiry under Part II, a witness stated he supplied from his own factory 75 per cent. of the glass bottles used by the perfumery manufacturers in this country, and that the perfumery manufacturers deny this. No action need be taken as the Committee can call for further evidence if this is considered necessary.—(July 10.)

Questions in Parliament.—Approximately 300 questions relating to the Act have been addressed to the Board of Trade, and in addition a large number to the Treasury. No reliable estimate of the cost of these answers can be given.—(July 11.)

Procedure.—It is intended, when the reports of the Committees now sitting have been received, to review the position with a view to seeing what alterations, if any, can usefully be made in the procedure under the Act.—(July 17.)

Opal Glass Shades have been made in large quantities in the Birmingham and Stourbridge districts, but several factories have shut down owing to trade depression and the output is now small.—(July 17.)

Complaints.—Since October 1, 1921, no complaints under Part II of the Act have been received that goods are being dumped from Germany.—(July 17.)

Synthetic Perfumes.—The Board of Trade is aware that toilet soap containing synthetic perfumes and dyes is being imported duty free into England, whereas when imported separately these perfumes and dyes are either prohibited or duty is demanded on them. It is not intended to introduce legislation to admit these chemicals free of duty.—(July 17.)

Glassware.—The case for making an Order (under Pt. II) relating to German-made glassware has been established. The question of Czecho-slovakian glassware will be considered during the debate on the Act which must take place before the summer recess.

On June 5, 5010 glass-bottle makers, including 1336 labourers, were registered in Great Britain as unemployed, as compared with 4357 (including 1345 labourers) on December 2, 1921. Separate figures for machine workers are not available.—(July 17.)

Reports.—The reports of the Committees on scientific and optical instruments, glass bottles, and gas mantles, have not yet been received.—(July 17.)

REPORTS

FIFTY-EIGHTH ANNUAL REPORTS ON ALKALI, ETC. WORKS. 1921. *By the* CHIEF INSPECTORS. *Pp.* 32. *London: H.M. Stationery Office*, 1922. *Price* 1s.

Plants have been working under quite abnormal conditions during the year, and the work of the Inspectors has been unusually difficult. The number of complaints received regarding nuisances has not been large, and fifty per cent. of those received related to the refining of petroleum and tar-oil, the manufacture of fish manure and organic acids, and other works over which the Alkali Inspectors have no jurisdiction.

The total number of registered works in England, Wales and Ireland during 1921 was 1342, a decrease of 41 during the year. The number of separate processes of manufacture under inspection was 2150, a decrease of 91. The tabulated results of determinations of acid gases escaping show that reductions have been effected during the year in all classes of works.

Alkali Works.—In all districts the percentage condensation of muriatic acid gas was good. Alterations of plant at one works have resulted in a reduction of 50 per cent. of the acid escape. One of the complaints received was due to a temporary insufficiency of draught.

Cement Works.—Rotary kilns have now attained a length of over 240 ft., and have not, apparently, reached their final stage of development. Although black smoke is seldom seen, attention is directed to the necessity for careful control of combustion, as in one case hydrogen sulphide was emitted owing to a deficiency in the air-supply. In connexion with the recovery of potash salts, further investigation is needed upon details in each particular installation, and especially as regards the choice of filtering material.

Sulphuric Acid Works.—The demand for sulphuric acid has been comparatively small and has resulted in an accumulation of stocks of spent oxide. At a number of works where pyrites has hitherto been used, plant suitable for the burning of spent oxide has been installed. American sulphur, either alone or mixed with spent oxide, is also being used, thus eliminating the difficulty of dealing with the cupreous-pyrites residues and obtaining directly a practically non-arsenical acid. The best possible means of dust deposition should be adopted when burning oxide, particularly when mechanical furnaces are employed. Filtration presents difficulties and the passage of the gases through a large unpacked chamber, although most efficient, involves loss of heat. The provision of baffles in flues often results in little deposition of dust owing to the locally increased velocity. More attention should be paid to the use of sumps in flues, the introduction of secondary air after the burners, and the electrical deposition of dust. The provision of oxides of nitrogen for the chambers by means of the ammonia-oxidation process is extending. A further substitution of fans for steam jets for the purpose of draughting chamber sets is recorded. Attention is dircted to the need of maintaining the efficiency of scrubbers attached to concentration plants.

Chemical Manure Works.—The average acidity of the gases escaping from scrubbing towers was equivalent to 0·06 grain SO_3 per cb. ft., as compared with 0·2 grain in 1903. Condensing flues play an important part in removing noxious compounds, and should be particularly considered where newer types of mixing plants are installed. An efficient scrubbing plant mentioned consists of a number of unpacked tower-chambers, each fitted with high-pressure water sprays, followed by two closely-packed water scrubbers, the latter being of considerable importance.

Sulphate and Muriate of Ammonia Works.—Owing to the coal strike, the high price of sulphuric acid and the low value of sulphur in spent oxide, these manufactures have been carried on under adverse conditions. The total quantity of ammonia products (expressed in terms of sulphate containing 25·75% NH_3) manufactured in the United Kingdom amounted to 253,253 tons, as compared with 397,937 tons in 1920. Activity is being displayed in the production of sulphate in a dry and neutral condition and in the recovery of muriate at coke-oven works. The heap system of purifying the foul gases from sulphate plants is found to be more satisfactory than the use of box-purifiers.

The increasing difficulties in disposing of spent liquors from the distillation of ammoniacal liquor have been specially investigated. The liquor is usually passed through settling pits in order to remove suspended matter, but phenoloid and other offensive vapours are evolved with the steam rising from the hot liquor, and local authorities often object to deal with the remaining effluent. The total volume of spent liquor to be handled in gas-works' practice is about 4000 galls. per ton of sulphate, and larger volumes are involved in coke-oven practice. In an appendix to the Report, methods of analysis are described, and it is shown that an average sample of effluent from the settling pits of a gas-works' sulphate-plant contains phenols equivalent to 0·8—1·5 g. $C_6H_5.OH$ per litre, in addition to thiocyanate and thiosulphate (*cf.* J., Skirrow, 1908, 58, Fowler and others, 1911, 174, Frankland and Silvester, 1907, 231). Devil liquors also contain hydrogen sulphide and hydrocyanic acid, and, as they are much richer in phenols, the practicability of submitting them to special treatment should be considered. The spent liquor from the stills has a high oxygen-absorptive power and develops a brown coloration which can be discharged by the addition of acid. It was found that by bringing the liquor into contact with waste combustion gases at a temperature near the boiling-point, a large proportion of the phenols together with any residual ammonia and pyridine could be volatilised. Further, the alkalinity of the liquor can be neutralised by the acid in the waste gases. A large-scale experimental plant has been erected, and further trials are being made; it is anticipated that by this means a deodorised and almost colourless effluent suitable for admission to the sewers will be obtained.

Tinplate Flux Works.—The preliminary cold-water treatment of scruff is being more widely adopted and analyses of chimney gases show considerably improved results.

Tar Works.—Abnormal conditions in the manufacture of coal gas have affected the character of the tar at some works, and in one case increased amounts of foul gases were produced. At several works the escape pipes from pitch coolers were inefficiently sealed. The tar distilled in the United Kingdom during 1921 amounted to 1,013,245 tons and the pitch to 384,416 tons.

Report on Scottish Works.—During 1921 there were 167 registered works in Scotland which operated 319 scheduled processes. In no case did the results of the chemical tests exceed the statutory limits. The depressed state of trade in comparison with the previous year (*cf.* J., 1921, 279 R) is shown by the following data:—Pyrites and spent oxide burned 71,416 tons, phosphates and bones dissolved 51,796 tons, salts of ammonia made (expressed as sulphate) 62,343 tons, tar distilled 148,608 tons, pitch produced 58,833 tons.

The condensation of noxious gases in chemical manure works has been improved as a result of the provision of additional condensing flues and careful control of the exhaust-fan. A market is required for the snowlike deposit of hydrated silica obtained. In the newer types of dens the acid steam evolved from freshly-made superphosphate is a cause of irritation. An improved quality of ammonium sulphate is being made, and the larger size of individual crystals now demanded is being obtained with vacuum saturators. For the dehydration of tar for road-making, additional stills of the continuous pattern have been erected.

Third Annual Report of the Governors of the Imperial Mineral Resources Bureau. *Pp.* 72. *Published by the Bureau, 2, Queen Anne's Gate Buildings, London, S.W.* 1. 1922.

This report, covering the calendar year 1921, relates to changes in personnel, the collection and dissemination of information, the staff, the forthcoming British Empire Exhibition, the unification of mineral statistics, and financial matters. The greater part of the pamphlet is occupied by appendices, one of which, filling 36 pages, presents very valuable review of the principal mineral dustries of the British Empire and foreign untries for the year 1921; another explains the forts the Bureau is making to unify methods returning and recording mining and metalrgical statistics. In the latter connexion it is orthy of note that, with but very few exceptions, e Bureau has adopted the British statute ton of 240 lb. as the standard of weight and the £ sterling the standard of value. The ambiguity of the rms "production" and "consumption" is iscussed, and generally this part of the Report ill prove very useful to those who have to deal ith statistical information.

During the past year the Bureau has issued a rge number of publications, many of which have een in great request. The series on the mineral dustry during the period 1913—1919 is now early complete. A statistical summary of production, imports and exports of minerals from 1913 1920 was also published. The valuable work on he iron resources of the world is nearing completion (Pts. I to V have just been issued). olumes on the mining laws of the Transvaal and ritish Columbia will be published shortly. A pecial compilation on the laws and regulations overning the employment of persons in lead mines nd lead manufactories in all parts of the world, nd a model code of mining ordinance for Kenya olony, were issued during 1921.

In the interest of economy the paid staff of the ureau has been reduced from 46 to 36, and other rrangements have been made to effect a total aving of £4000 per annum. Grants amounted to 16,800, of which £10,000 was contributed by the mperial Government.

REPORT ON THE ECONOMIC SITUATION OF BELGIUM AT THE END OF 1921, REVISED TO MARCH, 1922.

By R. F. H. DUKE, *H.M. Commercial Secretary, Brussels. Department of Overseas Trade. Pp.* 134. *London: H.M. Stationery Office,* 1922. *Price* 3*s.* 6*d.*

Before the war Belgium possessed many flourishing industries—chiefly coal-mining, metallurgy, textiles, glass-making, industrial chemicals, cement, bricks—and a comparatively small national debt. The war destroyed all these industries except coal-mining, deprived Belgium of her export trade and the assistance of German capital, and increased the national debt enormously. Economic recovery has, however, been wonderfully rapid, and the formation of combines, particularly in the metal, glass, textile, cement and building-material industries, has enabled the manufacturers to develop the export trade and to resist the economic stagnation more successfully.

By the end of 1920, 27 out of the 54 blast furnaces which existed before the war had been relighted, and the output of iron and steel was over one-half that of 1913. During 1921, however, owing to the steady fall in prices of metallurgical products and severe foreign competition, production declined, and manufacturers restricted themselves to working up imported raw steel. At the end of the year only 14 blast furnaces were in operation, but subsequently the receipt of foreign orders improved the outlook. The zinc industry, which suffered little during the war, was short of raw material, and owing to the high cost of coal and labour, production declined from 84,252 tons in 1920 (41 per cent. of the output in 1913) to 66,470 t. in 1921. Reconstruction has not been so rapid in the lead industry, which is of lesser importance (*cf.* J., 1922, 266 R). The commercial agreement with Luxembourg (*cf.* J., 1922, 202 R) has been opposed on the ground that pig iron can be produced more cheaply in that country than in Belgium, which has to import the ore, and it has been proposed to form a Franco-Belgian-Luxembourg cartel to control the output of Alsace-Lorraine, Belgium and Luxembourg.

An approach to the pre-war level of prosperity was made in 1920 by all branches of the glass industry except that of table-glass, but in 1921 conditions were less favourable, labour and export difficulties proving serious, and attention was turned to the establishment of a special export sales-organisation. The chief producers are to participate in erecting a large glass factory to utilise the Foucault process in the Kaiping coal-mining district of China. Like other textile industries, the artificial-silk industry has suffered during the past year, but demand is now said to be in excess of supply; the export in 1921 was 153 t. and the daily output is now about 12 to 13 tons. The cement industry has been prosperous and the export trade considerable; the product has been improved by adopting the British standard specification, but packing is still faulty.

In the chemical industry the situation is not good, consumers are holding stocks, and the wage question and German competition are causing difficulties. The output of superphosphate fertiliser is still below the pre-war level of 230,000 t., but that of ultramarine has increased, so that sales of the British article have declined. The Fours à Coke Semet-Solvay and Piette (capital, 40 million francs), which is the chief manufacturer of coal-tar products in Belgium, has been working on only a small scale since the armistice. Many of the Belgian companies formerly under German influence have been acquired by the Compagnie Belge pour les Industries Chimiques (capital 50 mill. fr.), which is closely connected with French interests.

Among minor industries the match industry has been most successful since the war, both in the home and export trade. The paper industry, centred in the Ardennes and in Brabant, reduced production during 1920 on account of German competition. In 1920 the output of coal was 22·5 million t., compared with 18·5 mill. t. in 1919 and 22·8 mill. t. in 1913; production, however, is insufficient to meet the demand and importation is necessary. Developments are in progress in the coal-mining industry to improve materials, methods, etc.

Exports from Belgium in 1920 amounted to 10,548,593 t., valued at 8,708,082,000 fr., and 17,160,355 t., valued at 7,147,327,000 fr. in 1921, 15·5 and 17·6 per cent. by value being directed to the United Kingdom in the two years, respectively. The chief exports to the United Kingdom in 1921 were as follows (in 1000 fr.):—Copper, raw, 8497 iron and steel 61,301; lead, crude, 7121; lead 3107 zinc, crude, 15,030; zinc 9915; cement 15,010; basic slag 6055; superphosphate 11,994; chemicals 8478 vegetable oils (not olive or groundnut oils) 17,005 dyes and colours 7074; pottery 2056; glass 49,296 iron and steel 149,619. In 1920 the imports were 11,946,448 t. (11,171,467,000 fr.) and in 1921

17,511,863 t. (10,054,583,000 fr.), the percentage supplied by the United Kingdom being 17·2 and 11·17, by value, in these two years. Values (in 1000 fr.) of some of the principal imports from the United Kingdom in 1921 were:—Salt 1481; olive oil, groundnut oil 1707; edible fats 1908; non-edible fats 6670; vegetable oils 11,946; hides 28,744; ores 6857; copper, raw, 4454; copper 2800; tin, raw, 5069; coal 39,958; iron and steel, raw, 17,350; iron and steel 21,902; tar, tar oils, mineral oils 27,097; soap 1050; chemicals 17,249; dyes and colours 6811; paper 2644; pottery 3375. The fluctuating value of the franc has adversely affected British trade with Belgium. British goods still retain a reputation for superior quality, but if prices are not considerably reduced, better terms of credit given and more punctual deliveries made, trade will diminish.

The natural resources, trade and industry of the Belgian Congo are discussed and the opportunities for British enterprise outlined.

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for July* 13 *and* 20)

TARIFF CUSTOMS EXCISE

Australia.—The operation of the duties on citric acid, chamois leather, metal cordage (not including aluminium cable) has been postponed until September 30. Negotiations are in progress with Canada and New Zealand for reciprocal tariff arrangements.

Belgium.—Export licences are now required only for sugar, syrups of all kinds other than pharmaceutical syrups, and molasses.

Chile.—It is proposed to apply an export duty on ores of copper and iron.

Egypt.—A list of import valuations for iron and steel goods is given in the issue for July 20.

France.—By a recent customs decision nickel pellets are admitted duty free.

French Colonies.—The export or re-export of opium, morphine, cocaine and their salts is prohibited. Opium and opium products directed to France or in transit through French Somaliland are not affected.

Germany.—Artificial honey, cocoa butter, cocoa products, and other food products no longer require an import licence. In future the surtax leviable when customs duties are paid in paper currency will be fixed weekly on the basis of the dollar exchange for the previous week.

Lithuania.—Export licences are now required for, *inter alia*, cast iron, brass, silver, gold, fuel, bones, hemp, explosives, and malt.

Mexico.—The export duty on beans has been reduced to 1 cent per kg. The internal taxes on petroleum and its derivatives have been modified.

Newfoundland.—A Commission has been appointed to revise the customs tariff.

Poland.—An export duty of 15 Polish marks per kg. has been imposed on crude mineral oil.

South Africa.—Special duties have been adopted to prevent dumping from countries with depreciated currencies. The Board of Trade and Industries recommends that certain materials used for manufacturing goods within the Union be admitted duty free. The duty on starch has been fixed at 1d. per lb. A Bill has been introduced to prohibit, regulate or restrict the importation of boots and shoes, and sugar.

Spain.—A customs duty of 85 pesetas per 100 kg. on sugar, glucose, liquid caramel and similar products and consumption duties of 45 pesetas per 100 kg. on sugar made in Spain and 22·50 pesetas per 100 kg. on glucose have now been enacted. The import duty may be reduced temporarily by 15 pesetas per 100 kg. if Spanish manufacturers raise their prices unduly. A schedule of modifications in the customs tariff is given in the issue for July 20.

Switzerland.—The temporary reduction of the export duty on scrap iron to 40 centimes per 100 kg. has been extended until further notice.

Tanganyika.—The export duty on hides and skins is suspended until December 31.

United States.—A copy of the Narcotic Drugs Import and Export Act may be consulted at the Department of Overseas Trade.

Yugoslavia.—A new scale of monopoly duties has been fixed for explosives.

OPENINGS FOR BRITISH TRADE

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence), 35, Old Queen Street, London, S.W.1, from firms, agents, or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

LOCALITY OF FIRM OR AGENT	MATERIALS	REFERENCE NUMBER

* Official Secretary, Australia House, Strand, W.C.2.

TRADE NOTES

BRITISH

Seychelles in 1920

Considerable progress was made during 1920 in the distillation of essential oils, the exports being valued at Rs. 420,104. Towards the end of the year the European demand for cinnamon-leaf oil practically ceased, the price fell from Rs. 12 to Rs. 4 per kg., and many distilleries had to close down. Only three tons of vanilla was exported, and the crop was the smallest on record. The vanilla vines suffer severely from a disease, which is now the object of investigation. The crop of coconuts reached the estimated total of 23,159,172 nuts, of which nearly 18 million was converted into copra; the increased crop, compared with 1919, was due to the enforced cleaning of the plantations. The manufacture of soap, for which much coconut oil is used, was discontinued owing to the difficulty of importing soda. Exports of rubber declined from 13·4 t. to 10·7 t.; progress was made in extending the coffee crop and in reafforestation; and the guano industry was restarted. Exports from the colony decreased in value by Rs. 389,422 to Rs. 1,711,955, owing to trade in copra re-attaining a normal level. Imports, valued at Rs. 1,716,408, increased, and a larger proportion than usual was derived from the United Kingdom.

FOREIGN

The New Bakelite Corporation

Following the legal action which resulted in the upholding of the Bakelite patents for the manufacture of phenolic condensation products, the Redmanol Chemical Products Co. has decided to combine with the General Bakelite Co. in order to prevent loss of goodwill, plant and organisation. The Condensite Co., controlled by the Redmanol Co., is also entering the new combine, which has been taken over by the Bakelite Corporation. The three companies will continue separately to manufacture and market their products, which supplement one another; thus galalith and "hexa" are made only by Redmanol, chlorine substitution products only by Condensite, and transparent material by Bakelite and Redmanol.—(*Chem. and Met. Eng.*, *June* 31, 1922.)

German Chemical Trade during May

H.M. Commercial Secretary at Berlin reports a slight improvement in the inland trade in coal-tar dyes. Foreign sales were satisfactory, and business remained at the level of the previous month in the Austrian Succession States, Holland and North Europe, but declined in Czechoslovakia, Finland and Belgium. Business was hampered in Northern Europe by offers of dyestuffs illegally exported from Germany, and by keen competition from many countries. The demand for pharmaceutical products increased, but that for chemicals continued to decline without, however, restricting full employment in the factories. Exportation was affected by fluctuations in the value of the mark and the world-market prices of certain chemicals were often reached and even exceeded. Supplies of raw materials improved, but soda had to be imported in bulk from France and Switzerland. Large orders for tinplate were placed in England and difficulties were experienced in obtaining supplies of packing paper, carboys, carbons, iron bars, etc.

Caustic Soda in Brazil

Owing to difficulties in obtaining supplies of caustic soda during the war, the Brazilian Government offered loans and concessions to encourage the manufacture in the country. This action resulted in the formation of the Cia. Brazileira de Productos Chimicos, which has erected a plant near Rio de Janeiro with a capacity of 5 metric tons of caustic soda solution (76°) and 10 t. of calcium chloride solution (35°) per 24 hrs. Since these products have been marketed imports of caustic soda have declined from 12,036 t., valued at 8,523,000 milreis, in 1920 to only 2899 t., valued at 2,567,000 milreis, in 1921 (milreis = 2s. 3d. at par, now 7·4d.). Although this heavy decrease was undoubtedly due largely to trade depression, the Brazilian demand for foreign caustic soda will probably be much restricted in future.—(*U.S. Com. Rep.*, *May* 22, 1922.)

REVIEWS

BASIC SLAGS AND ROCK PHOSPHATES. *By* GEORGE SCOTT ROBERTSON, *with a preface by* SIR EDWARD J. RUSSELL. *Cambridge Agricultural Monographs. Pp. xiv*+120. *Cambridge: The University Press*, 1922. *Price* 14*s. net.*

Much interest is being taken at the present time in the production of basic slags and in their value as fertilisers, and at the same time the not less important question of the manurial value of ground rock phosphates, and of the extent to which they can replace basic slags as fertilisers, is receiving much consideration. The monograph by Dr. Scott Robertson on basic slags and rock phosphates, which has been issued as one of the Cambridge Agricultural Monographs, appears therefore at a particularly appropriate time, and should be very useful to all agricultural teachers and agricultural chemists.

For a long time basic slag was not very popular with the British farmer. Whereas Germany, the largest producer, consumed at home nearly the whole of her millions of tons, it was not sufficiently appreciated in this country, in spite of the evidence obtained at Cockle Park and elsewhere, to prevent a considerable proportion of our relatively small production being exported. Under the stress of war necessities the British farmer at last learnt to appreciate basic slag, and during the years 1917 and 1918, though the home production was greater than ever before, it was all used at home. It was through experiments made with slag produced by the basic Bessemer process that the reputation of basic slag as a manure was established, and it seems almost tragic that when British farmers had at last learned to appreciate and use this fertiliser, changes in the steel industry have made it necessary again to undertake the whole process of determining by field experiments the value of basic slag relatively to other phosphatic manures. Most of the basic slag now on the market is not the same substance as the old Bessemer slag, from which it differs both in the phosphate percentage and in the solubility of its phosphate.

Closely related to the slag question is that of the fertilising value of ground rock phosphates, and this also has recently assumed new importance. The orthodox agricultural chemistry of the past taught that rock phosphates are of little or no value as manure until they are dissolved to form superphosphate. There have always been a few unorthodox persons who have maintained that ground rock phosphates have in themselves a high value, and during the past twenty years opinion has gradually been coming over to their side, as evidence has accumulated showing that, weight for weight of phosphate, nearly as good a result can in many cases be obtained from ground rock phosphate as from superphosphate, and that therefore, to a large extent at any rate, it is unnecessary and wasteful to use superphosphate.

Dr. Scott Robertson's little book is mainly taken up with a record of field experiments carried out on grassland in Essex with basic slags of different kinds, and with ground rock phosphates from North Africa, Florida and elsewhere. Sir E. J. Russell, the director of the Rothamsted Experiment Station, who is chairman of a Departmental Committee appointed to consider the question of the supply of basic slag, provides an introduction.

The opening historical statement and the review of previous experiments are short and might usefully be enlarged in a new edition. These sections are so incomplete that they hardly give a fair and balanced impression of the development of the use of slag and rock phosphates.

The really valuable part of the work is the account of Dr. Robertson's own experiments on grassland in Essex, which occupies by far the greater part of the book. These experiments were carried out on eight different farms on soils of three different types and are characterised by certain distinctive features. The improvement obtained is not measured merely by weighing the crops of hay, but careful botanical analyses were made, and the effect of the manure in changing and improving the kind of plants in the pasture is carefully discussed. The relation of the phosphatic dressings to the accumulation of nitrogen in the soil, and their effect on the soil bacteria, and on the soil acidity, moisture and temperature, are all critically examined in a scientific manner, and conclusions of much interest are drawn. The results in general show that rock phosphates "give results approximately equivalent to those secured from the high citric-soluble types of basic slag" and that whilst the low-soluble fluorspar basic slags have effected considerable improvement they "have undoubtedly proved to be less effective than either the high-soluble slags or the rock phosphates."

Dr. Robertson states his conclusions moderately, and the economic importance of the questions involved is so great that he might perhaps have been a little more emphatic in stating the conclusions at which he has arrived, even though they may sound unorthodox to those who hold that agriculture cannot prosper without basic slag.

The book has a good index and is illustrated with reproductions of a number of excellent photographs.

L'Azote. *By* L. Hackspill. *Pp.* xii+271. *Paris: Masson and Cie. and Gauthier Villar et Cie.,* 1922. *Price* 14 *francs net.*

This volume, which is one of a series of monographs included in the Encyclopédie Léauté, contains a well-written review of the principal processes of nitrogen fixation by an author who has had considerable opportunity for studying these in actual operation. The fourteen chapters contained in the book include a description of the technical manufacture of the more important nitrides and of calcium cyanamide, of the synthesis of ammonia, and of the fixation of nitrogen by the arc process. In addition, various operations subsidiary to the main process of fixation, such as the preparation of nitrogen and of hydrogen, the absorption and concentration of oxides of nitrogen and of nitric acid, and the formation of various ammonium salts are described; further, constructional details and the number of plants of various types known to be in operation are frequently given. In particular, the account of the Oppau and Merseburg synthetic-ammonia plants, including the methods employed in carrying out many of the subsidiary operations involved, is worthy of note. A special chapter is devoted to the use of abnormally high pressures by Claude, and further sections contain a general economic review of nitrogen fixation, of the utilisation of artificial nitrogenous manures, and of the production and consumption of nitrogen compounds in various countries.

On the whole, Prof. Hackspill is to be congratulated on the production of a very readable and well-arranged work, which appears to be exceptionally free from misstatements and from serious misprints. The statement on page 15 that nitrogen, on being activated by electric discharge at low pressures "devient lumineux pendant un certain temps, plus long si l'on refroidit, plus court si l'on chauffe" cannot, however, be accepted as completely accurate in view of Strutt's observation that an afterglow, which persisted at room temperature for slightly more than a minute, became extinguished in fifteen seconds at the temperature of liquid air. Similarly, misprints occur occasionally in the spelling of proper names. Thus, "Briegler" for "Brieglieb" (p. 17), "Scheffield" for "Sheffield" (p. 73), "Clause" for "Claude" (p. 84), and "Vant 'Hoff" for "Van't Hoff" (p. 156), in addition to other minor misprints, were noticed on reading through the volume, but small inaccuracies of this type do not detract from the general utility of the work, which forms a very acceptable addition to the literature of fixed nitrogen. The diagrams are excellent, particularly since many of them are marked with the actual dimensions of the plant illustrated, thus allowing a far more accurate conception of relative sizes to be obtained than is possible from purely diagrammatic sketches.

Principles of Leather Manufacture. *By* H. R. Procter. *Second edition. Pp. viii+688. London: E. and F. Spon, Ltd.,* 1922. *Price* 33*s. net.*

In 1903 Prof. Procter's "Principles of Leather Manufacture" replaced his still earlier "Text-Book of Tanning," published in 1885. The great advances made since then in the science and practice of leather manufacture have necessitated another edition, and the above volume replaces the first edition as the standard work on the subject and the final authority on all matters within its scope. The second edition contains 170 more pages than its predecessor, and its printing, illustrations and binding are worthy of its high position in technological literature. The general scheme of division into chapters adopted is the same as in the first edition, each chapter being expanded, several new ones added and an appendix inserted containing several original contributions by various authors.

Starting with a brief description of the living cell, the mechanism of putrefaction and fermentation under the influence of moulds, yeasts and bacteria is described. A chapter devoted to a full account of the antiseptics and disinfectants applicable to hides and skins is followed by a description of the origin and curing of the same, special reference being made to the cause and prevention of salt stains and the damage to hides caused by the warble fly. The chapter on the structure and growth of skin is illustrated by excellent photomicrographs by A. Seymour Jones and R. H. Marriott. The section dealing with physical chemistry as applied to the leather industry is greatly enlarged, special attention being given to the measurement and effects of variations of hydrion concentration and a chapter devoted to colloid solutions and the colloid state. A chapter on the chemistry of hide nearly completes the scientific as distinct from the practical part of the book. Henceforward the processes of leather manufacture are dealt with in the order in which they are carried out in the tannery, separate chapters being devoted to softening of hides and skins, depilation, deliming, bateing, puering and drenching, and pickling and depickling.

Of actual tanning processes, those by means of chrome, alum and iron are first considered, the two former in considerable detail. A very complete account of the vegetable tanning materials follows, occupying nearly 60 pages and containing many illustrations, and the tannage of sole leather with these materials is described, combination tannages being briefly dealt with. Accounts of the grinding and extraction of tanning materials and evaporation follow. The chemistry and analysis of oils and fats occupy 30 pages, and chapters on their use in leather manufacture are included. Dyes and mordants as used on leather, evaporation, heating and drying, maintenance of tanneries and disposal of waste products are treated in detail in the last four chapters.

In the appendix, full extracts, with a number of tables and diagrams, from the papers by the author and Wilson on the gelatin equilibrium are given. M. C. Lamb contributes a list of dyes suitable for use on chrome and vegetable-tanned leather, and papers by Atkin and Thompson on the determination and control of acidity in tan-liquors, and by W. R. and J. Atkin on the caustic alkalinity of lime liquors, are included.

Many practical books consist of a monotonous catalogue of processes, good, bad, and indifferent, of the majority of which it is extremely unlikely that the author has any personal knowledge. On the other hand, scientific teaching requires to be presented to the average tanner in a very clear way if [illegible] to listen to it. Prof. Procter, as a practical tanner, can give the manufacturer much valuable advice, and as an eminent scientist his gift of lucid explanation is such that his exposition of the science and theory of the industry can be profitably studied both by the non-practical man unacquainted with the industry and by the manufacturer desirous of understanding more of the principles underlying his processes.

Douglas J. Law.

REVIEW

Vol. XLII] AUGUST 15, 1922 [No. 15

THE TRAINING OF THE CHEMICAL ENGINEER*

R. F. RUTTAN

THE great field for the development of stable chemical industries in Canada is the utilisation of those natural resources which we possess in greater quantity, and more conveniently situated, than other countries. This need not call for original research but rather for adaptation to our conditions, of methods, principles and processes already known and well tried elsewhere. This is obviously the function of the chemical engineer, and it is from the young chemical engineer that we may expect the kind of industrial research which the country needs at present.

The scientific army of Great Britain has always consisted of a brilliant group of staff officers, but before the war England had not learned how to make the most of her mediocre ability. She did not recognise that without the scientific rank and file it would be impossible to staff the industrial research laboratories so as to compete with the more elaborate organisations of Germany and America. The English idea was that the two professions should be kept separate, each specially trained for its field of work, and that a chemical job should be done by a chemist and an engineering task by an engineer. The two, it was thought, should not be combined because the two subjects were too big for one man, save in a few exceptional cases. This is certainly true when the course of training does not exceed three years.

I think that most of the leaders in chemical industry in England are now willing to concede that the engineer should be taught sufficient chemistry to be able to appreciate the chemist's point of view, and that the chemist should know enough of engineering to realise that he can safely leave the practical application of the processes he devises in the laboratory to the engineer thus trained. The principle of "one man, one job," is thoroughly English, but it may be carried too far. One cannot overlook the important rôle played in the chemical industries of America and Germany by a class of scientific men who are neither highly-trained engineers nor highly-trained chemists, but who are recognised as a class, and many of whom have a great deal more in them than a knowledge of chemistry and of engineering.

It has been pointed out that as the engineer and the chemist become more highly trained and specialised, their paths become more divergent, and their points of view irreconcilable; in short, the experience of many heads of works is that the two types are largely incompatible. A works chemist defined the average engineer as "an empyric who has been trained on cotton waste and engine-oil"; and a works chemist has been described by an engineer as "an organic body more liable than any other of similar nature to spontaneous explosions." Chemists and engineers have also been called the physicians and surgeons of industry. On this analogy the chemical engineer would represent the general practitioner of the chemical industries; like the physician, his chemical knowledge enables him to see below the surface, to diagnose from physical signs unseen changes and conditions, and from his experience to find a remedy for any abnormal reaction. Just as there is a limited number of unseen organs in the human body to be studied and observed, so in a chemical works there is a limited number of operations, more or less invisible, going on in chemical units, each with its clinical thermometer, pressure-indicator, etc. attached to give early symptoms of any departure from the normal. The engineer in charge, like the surgeon, has to deal with the adjustment, repair and alterations of the anatomical units, the works, the accessible outward portions. Just as minor surgery constitutes a large part of the activities of the general practitioner, so frequent minor adjustments, alterations, improvements and repairs skilfully carried out form the larger part of the duties of the chemical engineer. Like the general practitioner, the chemical engineer should know his limitations and, when necessary, consult the specialist, the electrical or hydraulic engineer, or the chemist.

No analogy, however, should be carried too far, but it is worthy of note that the best specialists in any field of medicine or surgery are those who have spent years as general practitioners. Therefore knowledge of the general practice of chemistry and engineering in works is a very sound basis on which to build expert knowledge in either branch of science.

---

* The substance of an address delivered at a joint meeting of the Chemical Engineering Group and the Chemical Industry Club in the Savoy Hotel, London, on June 28, 1922.

During the past few years there has been a very prolific discussion regarding the best course of training for the chemical engineer. It has become generally recognised, on both sides of the Atlantic, that progress in industrial chemistry is based upon both engineering and chemistry, and that the Universities have failed to impart just the right type of education. This is due to the fact that the Universities are unable to teach the control of chemical reactions and the handling of materials on a sufficiently large scale. The best that can possibly be expected of the University in a course of four years is to give a broad and scientific foundation. After having once entered upon the work of his profession it is only in very exceptional cases that a man returns to the University for further training in research. Admitting the unsatisfactory and incomplete training which is now being given, the time seems ripe to consider some plan which will provide better-trained chemical engineers. The plan which, in my opinion, gives promise of meeting these requirements, is an adaptation of one which has been developed, and is now being tried, by the Massachusetts Institute of Technology, Boston. This unique scheme of education, which was evolved by a committee of engineers (of which Mr. A. D. Little was chairman) appointed by the Institute, has up to the present time completely realised the expectations of those who introduced it.

We recognise that chemical processes, whether on the laboratory or the factory scale, consist of a series of collected " unit " actions, such as pulverising, mixing, heating, roasting, absorbing, precipitating, condensing, crystallising, filtering, and electrolysing. The number of these basic unit operations is not very large, and only a few of them are to be seen in any particular works. To afford an insight into the real problems requiring industrial chemical research, the Institute mentioned established five or six chemical engineering and research stations in direct contact with important industries. These were selected with a view to bringing to the attention of the engineering student the largest possible number of the unit operations of which chemical processes are generally composed. The stations have a threefold function : (*a*) practical instruction in chemical engineering ; (*b*) instruction of ambitious foremen and others in the works in the fundamental principles governing their operations ; and (*c*) advancement of industrial research in special industries. The equipment of each station consists of a small building of one storey which contains a small reference library and a very complete collection of photographs and drawings of apparatus and machinery utilised in the local industry, but not installed in the locality ; a conference and lecture-room to accommodate fifteen or twenty people ; a small laboratory with benches for the same number an office for the station director ; and a laboratory for specialised industrial research, with space and equipment for five graduate research assistants. The cost of such an equipment would be from 10 to 20 thousand dollars in different industries.

According to the arrangements at the Institute the students leave the University about the middle of their fourth year, and spend the period from January to September in moving from station to station, spending about six weeks at each. An instructor is in charge of each station, and maintains the same strict discipline among the students as is found at the University. Each day's work is carefully planned, and daily lectures on different stages of the process form a part of the system.

The five-year course is designed to fulfil the following objects :—(1) To acquire a first-hand knowledge of the processes, plant and machines in the equipment. (2) To study the chemical control of industrial processes through the laboratory, and to acquire ability in the interpretation of laboratory data in terms of factory practice. (3) To obtain a general knowledge of modern methods of factory management and control, together with methods of apportioning cost of manufacture. (4) To obtain the wider viewpoint which comes from contact with those who are employed to superintend or carry out factory operations, and to acquire the degree of confidence in handling industrial processes and large-sized apparatus which comes from actual participation in the work of the plant. (5) To acquire that inspiration for further work in science and research which intimate contact with large progressive industries inevitably affords. On returning to the Institute to complete his fifth year, the student follows a course of advanced lectures and laboratory work, the value of which he will appreciate as the result of his experience in the works. The above description is the substance of the report of the committee presided over by Mr. A. D. Little.

This, in outline, is the object and method of this new plan of educating chemical engineers. It is our purpose to adopt a modified form of it in Canada, and this will require co-operation among the engineering faculties in Canadian Universities on the one hand, and a successful appeal to the captains of Canadian industry on the other. The Universities must agree upon the necessity for a five-year course in chemical engineering, and be convinced that one year spent chiefly in works' training is the best way of employing the students' time. Success or failure will depend very largely upon the manufacturers ; without their cordial co-operation and assistance the plan is obviously doomed to failure. In the United States every industry invited gladly accepted the opportunity of having a station in the works. The Honorary Advisory Council for Scientific and Industrial Research has appointed a committee to look into this question and to formulate a plan fo putting it into effect next year. It seems to me a very obvious and effective method of bringing into closer relation the Universities and the industries of Canada, enabling the former to ascertain the important industrial problems of the country, and giving the industries an opportunity of utilising in part the teaching and research powers of the Universities. Not only would this scheme give our students in chemical engineering a range of experience impossible to obtain otherwise, but the stations could offer special courses in the technology of their industry to superintendents, foremen, etc., thus forming a sort of university extension in chemical industry. The plan lends itself with peculiar effectiveness to the development of industrial research at each station. The director in charge of the station would obviously be a well-trained chemist or chemical engineer who has specialised, or intends to specialise, along the lines of the particular industry or industries with which he is connected.

The application of this scheme of training to Canadian conditions will not be easy. In the first place, the total number of graduates in chemical engineering and chemistry in Canada is less than is annually turned out by the Institute of Technology; hence the field from which we can select is smaller. The average student at the Institute is financially better able to spend the extra year, with its additional tuition fees and travelling expenses, than is our Canadian student. Again, few industries are on a scale comparable with many in the United States. But these difficulties are not insuperable. There is little doubt that industrial chemistry is offering such a future to our technically-trained graduates that chemical engineering is rapidly becoming the most attractive career for the engineering student, and the required number will soon be available. If the universities gave the Bachelor degree at the end of four years and a Master's degree in Science after five years; if the fees were made as low as possible and substantial Government assistance be given to these training centres, the obvious value of this practical training would soon create a competition among the students for the privilege of being admitted to the course.

The station in each centre would become the scientific bureau of information and research for the local industries, and would go far to introduce an atmosphere of science into those industries in which chemistry plays a part.

Finally, I feel strongly that the chemical engineer so trained is just the type of man to develop our industries. He would be a University man familiar with the engineering problems presented by chemical industries, one whose capacity for initiative and for attacking scientifically an industrial problem would be many times that of the present science graduate, however good his university training may have been.

CONSTRUCTIVE INDUSTRIAL HYGIENE IN THE INDIARUBBER INDUSTRY

C. A. KLEIN

EARLY in 1921 the Home Secretary, under Section 79 of the Factory Act of 1901, certified as dangerous the following processes incidental to the manufacture of indiarubber and indiarubber goods :—

(*a*) Vulcanising by means of the cold cure process or by any other process involving the use of carbon bisulphide, sulphur chloride, carbon-chlorine compounds or benzol (pure or commercial);

(*b*) Any process involving the use of lead or compounds of lead.

This certification by the Home Secretary is a necessary preliminary under the Act when it is intended to institute regulations for the hygienic control of an industrial process.

Shortly after the certification of the above processes as dangerous, the Secretary of State issued draft regulations which it was proposed to institute in connexion with these processes and, as prescribed, the draft regulations were submitted to those concerned and interested in the matter. After mutual criticism and discussion, a final form was agreed and Statutory Rules and Orders, dated March 31, 1922, now known as the "Indiarubber Regulations, 1922," came into operation on May 1 of this year.

The regulations divide the above-named processes into two kinds, viz., "fume processes"—*i.e.*, those referred to under (*a*) as above—and "lead processes," or those described under heading (*b*). The regulations for the two types of processes are almost entirely distinct, but few having dual reference.

In the regulations dealing with "fume processes," the essential feature is protection against the injurious effects of the vapours of volatile solvents used in indiarubber manufacture, the provisions being for minimum age of employment, limitation of hours worked, prohibition of the use of such processes in the open air, the application of exhaust draught or (when only benzene—pure or commercial benzol—is used) of efficient ventilation, the adoption of means to minimise the amount of vapour entering the air, messroom, medical examination at prescribed intervals, maintenance of health register, and rules for the re-employment of persons suspended by the certifying factory surgeon.

These new regulations supersede the Special Rules in operation since May 1, 1898, for "The vulcanising of indiarubber by means of bisulphide of carbon," and are more comprehensive and applicable to processes in which other volatile products are used.

The inclusion of liquids containing benzene and the carbon-chlorine compounds, indicates the increased employment or introduction of such compounds in the rubber industry and implies that the toxicity of the vapours of these compounds has been definitely established by practical experience. The toxic properties of the vapours of such bodies have been known for some time and the new regulations will cause little surprise—in the opinion of some, they were long overdue.

There has recently been much discussion as to the toxic effects produced by the vapours of the volatile thinners used in painting operations, and, as certain of the volatile thinners are common to the paint and rubber industries, the recognition of these vapours as dangerous in the rubber industry has an important bearing on the question under discussion. It has been suggested that the conditions obtaining in the two trades are not comparable, but as yet no evidence has been brought forward in support of this contention. The question at issue, though complicated, as are all questions involving the resistance of the human body, must be studied in its broadest aspect, for in no line of inquiry is the old saying that "one man's meat is another's poison" better illustrated. Personal idiosyncrasy plays a large part in these matters and until the subject has been carefully studied, it would appear as if Rolands and Olivers can be produced in about equal numbers, and the true position will not be known until the many and varying factors involved have been carefully considered.

The regulations for "lead processes" closely follow in principle those which in recent years have become standard in this country for all processes involving exposure to lead compounds, and provide for a minimum age of worker, exclusion of any female under 18 years of age from any lead process, application of exhaust-draught for the removal of lead dust at (or as near as possible to) its point of origin, mess-rooms, regular supply of clean overalls, accommodation for clothing put off during working hours, washing facilities, medical examination, maintenance of health register, rules as to the re-employment of workers after suspension by the certifying surgeon, and finally, facilities for the sampling of materials by Government inspectors.

The final requirement, which refers to the sampling of materials used, follows the practice which has been in vogue for some years in connexion with the use of lead compounds in the manufacture of pottery, and has been recently incorporated in the Women and Young Persons (Employment in Lead Processes) Act, 1920. In the latter case, as in the Indiarubber Regulations, the provision is made in order to afford samples, from the examination of which the process is to be classified as a 'lead process' or otherwise.

The test employed is the Thorpe solubility test by which the solubility (expressed in terms of PbO) of the material in 0·25 per cent. hydrochloric acid, is determined: one gram of the material being shaken for one hour with one litre of acid at common temperature and afterwards allowed to stand for one hour before the solubility is determined. The basis for the classification of operations prior to that of incorporation, is the solubility of the dry material, and, as it has been found that the test cannot be applied to mixtures containing rubber, the incorporation processes are classified on the basis of the solubility of the mixed mass as calculated from the solubility of the dry material and the quantity of the same in the mixture. Materials having solubilities not exceeding 5% when determined by such methods, are regarded as innocuous and processes involving their manipulation are not "lead processes": consequently, the provisions of the Regulations do not apply thereto.

The Lead Regulations, although new to the indiarubber industry, have been in operation in other industries for many years, and embody the principles which experience has shown to be of fundamental importance.

It does not appear to be known, except by those who have immediate interest in the subject, that this country was the pioneer in the study and control of industrial lead poisoning and that the progress made is regarded as a unique demonstration of the successful application of the science of industrial hygiene—a science which, to-day, is making rapid strides in spite of its comparative infancy. In Great Britain there were over 1000 cases of industrial lead poisoning in the year 1900. To-day, the annual figure is about 200, and this remarkable improvement has been effected without any serious interference with the progress of industry.

During the last twenty years, lead and its compounds have been more largely used than hitherto, whilst, as has been shown, the incidence of poisoning has fallen sharply. This progress is due to sympathetic co-operation between the officials of the Home Office, the employees, and the manufacturers. In no single case has it been deemed necessary to prohibit the use of compounds of lead, despite the occasional outbursts of certain well-meaning but uninformed and ill-advised amateurs who have clamoured for prohibition as the only panacea, heedless of any consideration of the economic aspects. Nothing is more conducive to lasting progress in industrial hygiene than harmonious co-operation of employers, employees and Government Departments: fortunately, it i in this way that English industrial hygien is proceeding.

It is not here suggested that the limit o improvement in respect to industrial lea poisoning has been reached, for there is clea evidence to show that further reductions ar possible, and there is little doubt that thes reductions will be made in due course. Th whole of the accumulated evidence goes t show that the problem of industrial lea poisoning is essentially one of dust, or to use the words of Dr. Legge* (H.M. Medical Inspector of Factories):—

"On the practical side little more is to be learned as to how lead poisoning is caused, and it can be taken as axiomatic that all risk lies in the inhalation of dust or fume. These removed or prevented, there would be no lead poisoning."

Nothing could be more definite or helpful than such a conclusion and the direction in which efforts must be concentrated is clearly defined—a position which is in striking contrast with that obtaining some few years ago when, at frequent intervals, those handling lead compounds were scared by the publication of alleged discoveries and alarmist theories as to sources of poisoning which proved costly to investigate and were invariably found to exist only in the imagination of their authors.

The lead compounds used in the rubber industry are litharge, and to a smaller extent, white lead, red lead, and basic sulphate of lead. These products are used in the dry form in mixture with other powders and are incorporated in rubber on slowly-revolving, heated "mixing" rolls. The dry powders are distributed by hand over the rubber as it passes through the heated rolls, and the operation is continued until all the material has been added and is thoroughly incorporated.

The cases of lead poisoning arising in this industry occur among those engaged in weighing out dry lead compounds and, to a much greater extent, among workers employed at the incorporating rolls. In both cases the danger is clearly attributable to dust, aggravated in the operation of incorporation by the current of hot air which rises from the rolls, carrying with it a certain quantity of lead dust. As an example, Legge and Goadby† instance an ndiarubber factory for which the records of poisoning are available before and after application of exhaust ventilation over the heated "mixing" rolls. Before the alteration was made, out of fourteen men employed thereon, ten showed a blue line, five were markedly anæmic, one had weakness of the wrist and two weakness of grasp. In a period of ten years after the application of exhaust ventilation, only one case had been reported.

The total quantity of lead compounds used n the indiarubber industry is very considerable, but the distribution of cases of poisoning bears no sensible relation to the weight distribution of the raw materials. In this industry, as in others, it is found that controlled workers may use large quantities of lead compounds without ll-effects, whilst in the hands of careless workers, or when used in unprotected apparatus, small quantities of lead compounds may give rise to a large number of poisoning cases.

There is a growing tendency in the lead industry to centralise the dangerous processes so that they can be operated by a small number of workers producing materials which are much less toxic than their separate constituents. It is obvious that this method is the only scientific and rational solution of the problem, and its application where possible should need no advocacy.

As an instance of what has already been successfully done, mention may be made of low-solubility lead silicate which is now used in large quantities in pottery work. This product, which contains approximately 65 per cent. lead oxide, combined with 35 per cent. silica, has a solubility of less than 5 per cent. when determined by the Thorpe solubility test, and can be used by the potter with comparative safety, being much less soluble than white lead, litharge, red lead or even the lead silicates formerly used. In this case, it has been possible to render the lead comparatively innocuous by chemical means, but there are industries in which this is not desirable and therefore alternative means have had to be found.

In certain industries, it was formerly the practice to purchase dry lead compounds for use in operations where they would be ultimately wetted by water, and, owing to the dust created in the handling of these dry compounds, an unnecessary amount of lead poisoning occurred: this has since been obviated by substituting water pastes for the dry compounds, thus overcoming the risk of poisoning through dust in the production of the lead material and its subsequent use.

The Indiarubber Regulations of 1922 have given an impetus to progress in another direction, and mixtures of pure rubber with various lead compounds have recently been put on to the market. The mixtures, which consist of 80 parts of lead compound incorporated with 20 parts of pure rubber, are sold in the form of thin sheets which are homogeneous in composition, and are used in the incorporating rolls in the place of dry lead compounds. In practice, it has been found that the mixture incorporates with the other ingredients quite satisfactorily on the rolls and a demand for the product has been established. The material is produced in lead factories where there are already in operation the most up-to-date methods of hygienic control under the supervision of those daily concerned with the handling of lead products in large quantities. It is obvious that no lead dust can be created by the indiarubber manufacturer in the handling of this mixture and that it is entirely free of danger. The Factory Department of the Home Office has given the matter serious consideration and has decided that the mixtures are neither "dry compounds of lead" nor "dry mixtures containing dry compounds of lead," and therefore, that any process in which the mixtures are used, is not a " lead process " to which the Indiarubber Regulations, 1922, will apply.

---

* Annual Report, Chief Inspector of Factories, 1918. Cmd. 40, p. 66.

† Legge & Goadby. Lead Poisoning and Lead Absorption. Arnold: London, 1912, p. 201.

By substituting this material for raw lead compounds, the rubber manufacturer will not only be free of control in respect to the use of lead compounds, but will at the same time, have the satisfaction of knowing that his work-people are handling a material which cannot, in any normal circumstances, exert an injurious influence on their health. There would appear to be no reason why the material should not be generally used in the indiarubber trade to the exclusion of raw lead compounds, but in particular, it seems to be eminently suitable for small manufacturers whose use of lead compounds is necessarily limited, and to whom the installation of apparatus and control demanded by the new regulations might be somewhat onerous. The future progress of the material will be watched with great interest because it is a fresh advance in modern industrial hygiene, the aim of which should be, not the destruction of industry, but its maintenance coincident with improvements in the hygienic conditions of employment.

THE THIRD INTERNATIONAL CHEMICAL CONFERENCE

THE Third International Conference of Pure and Applied Chemistry was held in Lyon from June 27 to July 1, Prof. C. Moureu (France) again presiding (*cf.* J., 1921, 267 R). The 100 to 120 representative chemists who attended were delegates from the twenty-four countries composing the Union. The delegates from the Federal Council of Pure and Applied Chemistry, the English section of the Union, were Sir W. J. Pope, Dr. T. H. Hewitt, Prof. T. M. Lowry, Dr. S. Miall and Dr. E. Mond. Canada was represented by Mr. A. T. Charron and the United States by Dr. C. L. Parsons, Prof. E. Barlow, R. B. Moore, and L. W. Washburn.

The Union discussed a large number of questions of interest to the chemical community as a whole and with the aid of its numerous committees came to a number of conclusions which will be submitted to the chemical organisations of the countries which compose the Union. A few of the conclusions thus arrived at are summarised below.

Nomenclature.—The question of introducing such unifications and conventions into the methods of naming and describing chemical substances as will facilitate the production of indexes in the chief languages which will be interchangeable as far as possible was discussed at length. On the motion of Sir W. Pope, it was decided that all questions of chemical nomenclature should be submitted for consideration to the editorial staffs of the chief chemical journals and that the work of the Committee should be restricted to the discussion and criticism of the reports received from the editorial staffs. A Committee consisting of Messrs. Greenaway, Marquis and Patterson was appointed to prepare a complete system of nomenclature that could be used by all the journals devoted to chemical science and technology. It was decided to publish the report of the Committee on biochemical nomenclature.

Bibliographical Contractions.—It was recommended that the abbreviations of the titles of periodicals used by " Chemical Abstracts " should be adopted and that a title not printed in Roman type should not be translated but transcribed in the manner proposed by the periodical itself. In accordance with the wish of the National Research Council of Japan the proposal to abbreviate the word " Japanese " to " Jp " and not " Jap " was accepted. Further resolutions bore on the establishment of central bureaux of bibliographical documentation and the use of the decimal system of the International Institute of Bibliography for classifying papers on chemical subjects.

Physico-Chemical Standards.—The work done by this Committee related chiefly to the provision of a further scientific worker for the staff of the Bureau of Physico-Chemical Standards, hitherto supported entirely by contributions from Belgium.

Research Chemicals.—To avoid delay in obtaining practical results the Committee has restricted its work to accurate descriptions of the qualities required in common analytical reagents; the descriptions are to be published in an international codex. When this task has been accomplished attention will be paid to chemicals used for purposes other than analysis. In addition to a resolution aiming at facilitating the work of the national delegates on the Committee, it was proposed that, in the volumetric estimation of the halogens in seawater, pure sodium chloride should be used as a standard in preference to standard seawater.

Technical and Industrial Products.—This Committee pointed out the utility of lists of manufacturers of chemical products and suggested that the example set by Great Britain in this respect should be followed by the other adherent States. The lists should be kept in Paris at the central bureau, but to avoid excessive centralisation, a delegate in each country should be appointed to receive copies of all the catalogues and documents sent to the Bureau.

Thermochemical Standard.—Benzoic acid was recommended for use in standardising calorimeters, the heat of combustion of 1 g. weighed in air being fixed temporarily at 6324·15 cal., *i.e.*, 6319·15 cals. per g. *in vacuo*. The standard acid, prepared by the Bureau of Standards, Washington, can be obtained from the Institut International d'Etalons Physico-chimiques at Brussels. Authors who publish dat on the heats of combustion are asked to quote th figure they have adopted for the heat of combustio of the benzoic acid used in standardising the calorimeter and, as far as possible, to give their result in absolute units.

The report of the Committee on tables of constants, proposing the establishment of an international fund for its work, was adopted and pr gress was made in discussing the possibility devising an international patent scheme. It anticipated that the Union will be able to issue i various tables of constants of the elements, dealin with isotopes, radioactivity and atomic weight for 1923 at the end of the present year. Repor presented by the Committees on food preservatio fuels, ceramics and industrial hygiene were al approved.

During the past three years the Union has necessarily been occupied largely with settling the details of its organisation and with organising formal matters of international interest, such as the production of tables of constants of the elements. It is felt that the time has now come when the programme of the annual meeting may profitably include the discussion of scientific and technological problems of broad chemical interest, and a beginning was made at Lyon with addresses by Prof. L. Vignon, on the early history of dyestuff manufacture in Lyon, and by Prof Perrin, on the discontinuity of matter. It is proposed that henceforth a series of addresses, devoted to broad chemical problems, not matters of detail, shall be presented for discussion at each annual meeting.

The following officers of the Union were elected for a period of three years:—President: Sir William Pope; Vice-Presidents: Prof. W. D. Bancroft, Ithaca; Prof. E. Billmann, Copenhagen; Prof. E. Paterno, Rome; Prof. E. Votocek, Poland; General Secretary, Jean Gerard, Paris. At the conclusion of the Conference it was decided to hold the Fourth International Chemical Conference in Cambridge, England, from June 17 to 23, 1923.

The Committee at Lyon created an admirable organisation for facilitating the work and promoting the comfort of the delegates; numerous visits to works of a most interesting and instructive character were arranged and the delegates were entertained most hospitably at many social functions. The proceedings terminated with a banquet offered by the Chamber of Commerce of Lyon.

At the close of the Conference, many delegates left by special train for Marseilles to attend the opening of the second congress held by the Société de Chimie Industrielle.

MEETINGS OF OTHER SOCIETIES

BRITISH PHARMACEUTICAL CONFERENCE

The fifty-ninth annual meeting was held in University College, Nottingham, from July 24 to July 27 under the presidency of Prof. H. G. Greenish, who delivered an address upon "Pharmacognosy and the Pharmaceutical Curriculum." Pharmacognosy, he said, was a field of knowledge that the pharmacist was peculiarly fitted to cultivate provided he had received a sound scientific training. The training in pharmacognosy should be of a more general and practical nature than was at present often the case, and should include the determination of diagnostic characters by means of the lens or microscope or by qualitative chemical tests. A detailed syllabus, however, was disadvantageous as it restricted freedom of thought and the development of that spirit of inquiry which was essential to progress. In the advanced course of instruction and in the Major examination, more stress should be laid upon the identification of powdered drugs, the analysis of mixed powders and the assay of drugs by chemical methods. Opportunity for postgraduate work was very necessary and every inducement should be offered to the student to undertake it. The Universities of Manchester and Glasgow had accepted pharmaceutical subjects as part of the examination for the degree of Bachelor of Science, and if the University of London could be induced to do the same a considerable step forward would be made. The student who had attended advanced courses of instruction could take the degree of B.Sc., and then proceed without difficulty to the degree of Doctor of Philosophy, the requirement of the University of London being broadly two further academic years of study and the presentation of a thesis on an approved subject. The field of pharmacognosy was so wide and the problems awaiting solution so diversified in their nature that there would be no difficulty in selecting subjects suited to the varied abilities of the students. Great assistance would be rendered in this work by the establishment of an experimental station similar to the Pharmaceutical Experimental Station of the University of Wisconsin at which the material necessary for investigation could be grown and experiments carried out. The determination of the Pharmaceutical Society to foster its scientific work more in the future was one of the most hopeful signs for the future of pharmacy, and would assist the Society in establishing its position as a learned society.

In a paper entitled "A Contribution to the Study of Strophanthus" Dr. K. Saaman described a variety of strophanthus—*Strophanthus preussii*—from Southern Nigeria, and showed that whereas this drug acts powerfully on the heart, it has a comparatively negligible action on the blood vessels.

Mr. T. E. Wallis contributed a paper on "Some Characteristics of Wheat Starch." Since wheat starch closely resembles barley starch it is difficult to identify either starch in mixtures of the two. The author's experiments indicate that wheat starch can be identified by measuring the diameter of the largest grains, which vary in diameter from 15 to 45 microns, reaching a maximum of about 50 microns, whereas those of barley never exceed 40 microns, so that if the starch contains any number of grains measuring 40 microns and over the presence of wheat starch is established.

Prof. Greenish and Miss C. E. Pearson presented "A Note on the Occurrence of Santonin," in which they reported upon the examination of several species of *Artemisia* suggested as possible sources of santonin. *Artemisia brevifolia* from Gurez was found to contain about 1 per cent. of santonin, but a sample of "estafiate" sent from Mexico consisting of two distinct species of *Artemisia* (*A. mexicana*, Willd, and *A. redolens*, Willd.) and samples of *A. Abrotanum*, *Linn.*, and *A. vulgaris*, Linn. contained none.

A paper on "The Extraction of Quinine and Strychnine from Solutions of Varying Hydrogen Ion Concentration" was read by Mr. N. Evers, who described a method for separating strychnine from quinine based upon the fact that strychnine may be completely removed from a twice normal solution of hydrochloric acid by chloroform, whereas quinine is only removed to a very slight extent. The determination of Easton's syrup requires much less time with this than with other methods.

A detailed study of "The Rapid Estimation of Quinine Salts in Tablets" was presented by Messrs. S. G. Liversedge and F. W. Andrews, Mr. C. W. Gosling described in detail the Michell viscometer, and other contributions included:—"A Further Note on the Ether-Solubility of Scammony Resin," by H. Deane and W. E. Edmonton; "A Note on Acetum Scillae" by J. H. Franklin and G. G. Hammond; "A Note on a Ferrocyanide Coloration of Tincture of Chloroform and Morphine B.P. 1885," and "A Note on Cherry-Laurel Water," both by C. M. Caines.

BRITISH ENGINEERING STANDARDS ASSOCIATION

The fourth annual meeting was held on July 13 in the Institution of Civil Engineers. The Chairman, Sir A. Denny, in presenting the annual report said that nearly 2000 engineers now gave their time and experience to the Association. During the past year 72 new and revised specifications were issued and 39,000 publications sold, in addition to a large number of aircraft specifications distributed for the Air Ministry. Expenses totalled £17,000, of which industry, despite trade depression, contributed £9300, the remainder coming from the Government, the India Office, and the Governments of the Dominions overseas. After reviewing the work of the various sections of the Association Sir A. Denny asked for more financial support from industry so that the Association could carry out work in hand and increase its activities in the future.

CORRESPONDENCE

THE CHEMIST AND THE MANUFACTURER

Sir,—The following random thoughts have been evoked by reading an article in the *Journal of Industrial and Engineering Chemistry* (Eller, June, 1922, p. 544), headed "Can the College do anything for Industry?" and dealing with the ever-green question of training the industrial chemist.

What is the ideal industrial chemist? Ask the professor. Ask the works manager. Widely divergent definitions would be advanced according to the standpoint of the one defining. The definition depends on the view taken as to the needs of industry. The professor's slogan is "Science," and the manufacturer's counter-cry is "Profits." It is left to the ideal industrial chemist to provide a common standing ground.

To the unbiassed, broad-seeing observer one of the wheels of industry's chariot must be chemical knowledge, and such wheels in the form of good, all-round chemists are to be obtained from the professorial wheel-wright. The owner of the chariot, that is the manufacturer, must, however, do his own fitting, and there must be a trial run to rub the bearings smooth. Reduction in running-costs must not be expected immediately.

A cause of disappointment may be that the manufacturer is not clear as to what he wants from his chemist. He appoints a chemist perhaps as he tries a new, much-advertised machine. He finds that the working is not quite so automatic as the advertisements claimed. It should be realised that the young graduate, although full of new knowledge and enthusiasm, inevitably requires some initial leading in the ways of industry. Failing a co-operative and sympathetic attitude from the employer, there is very quickly an over-heated bearing, the chariot moves but slowly and science is condemned wholesale.

Narrowness of view is by no means confined to the employer of chemists. The University professor is, of course, essentially limited in outlook—at least according to the man of the industrial world. Goggled eyes are indispensable in his make-up in the caricatures; and he justifies the world's opinion when his students are let loose on the arid, stony plain of chemical manufacture, with the idea that the few short years of cloistered chemical study, and the possession of the coveted alphabetical handle to the name, are all that is necessary to cause the plain to bloom and blossom wherever they may go. No, it would be a move towards the ideal co-operation of manufacturer and chemist if the latter came from the University with the smallest opinion of his acquisitions, and the realisation that the first step in growing flowers of the industry and science strain is to clear the ground of stones. The stones are the manufacturer's doubt, distrust and lack of sympathy with the aspirations of science. Can these be removed? Doubtless it is generally a long and tiring process, but possibly judged worth while by those fortunate ones who have now arrived at the flower-gathering season.

In conclusion, the moral now appears. Manufacturers, tell your chemist clearly what you want of him, and use him to the full extent of his abilities. Universities, broaden your teaching and outlook, scrap the goggles. It might then be found that the college *was* doing something for industry.—I am, Sir, etc.,

Alan A. Drummond.

Iver, Bucks.
July 25.

PERSONALIA

Dr. M. O. Forster has been appointed director of the Indian Institute of Science, Bangalore, and will take up his new duties early in November.

Mr. J. F. Smith has been appointed director of research to the Commercial Solvents Corporation, United States.

Dr. G. Senter has been selected by the University of London Graduates' Association as candidate for the vacancy in the representation of science graduates on the Senate of the University of London.

Dr. T. M. Legge, of the Home Office, and Dr. S. Miall have been appointed the British representatives on the advisory committee on industrial hygiene of the International Labour Office.

The Trustees of the Beit Scientific Research Fellowships have re-elected Mr. H. L. Riley and Mr. W. A. P. Challenor to fellowships for the year 1922–23 and elected Mr. H. W. Buxton to a fellowship for the same period. The fellowships are tenable at the Imperial College of Science.

The Italian Ministry of Industry has appointed Professors M. G. Levi, Nasini, Parravano, and Scarpa to be members of the permanent Committee for the Italian Chemical Industry (*cf.* J., 1922, 9 R). Prof. G. Varino has been appointed president of the Royal Technical Institute in Mantua.

Dr. P. Riebensahm has accepted the post of professor in charge of the metallurgical institute of the Berlin Technical *Hochschule*; Dr. H. Meerwein has succeeded Prof. H. Klinger in the chair of chemistry in Königsberg University; Prof. Wilke-Dörfurt has accepted the professorship of pure and technical chemistry in the Stuttgart Technical *Hochschule*; and Prof. E. Terres, of Stettin, has been awarded the prize of the German Bunsen-Gesellschaft for his researches in inorganic chemical technology, carried out in the Karlsruhe Technical *Hochschule* and published during 1920–21.

* * *

All will regret the death, at the age of 75, of Dr. A. Graham Bell, the inventor of the telephone.

Dr. Jokichi Takamine, a prominent Japanese chemist, has died at the age of sixty-seven.

The death is announced of Prof. F. Hofmeister, formerly professor of physiological chemistry in Strasbourg University.

The following deaths are announced from Germany:—Prof. H. Rubens, director of the Institute of Physics of Berlin University; Dr. K. Schaefer, professor of chemistry at Leipzig University; and R. Nöllenburg, founder of the Deutschen-Erdöl-A.-G.

NEWS AND NOTES

FRANCE

Industrial Notes

Chemical Industry.—The Deguide process for recovering sugar from beet molasses by means of baryta (*cf.* J., 1922, 244 R) promises to become increasingly important, as it is now proposed to utilise the baryta for defecating the raw beet-juice. In this way it will be possible to recover all the potassium and nitrogen compounds that pass into the extracted juice in the diffusion process. Apart from their monetary value, these salts constitute ideal fertilisers for the sugar beet, and their recovery might lead to an extension of beet-growing in France. The Société des Produits Azotés is now producing a new fertiliser, "phosphazote," which consists of superphosphate of lime and urea, the latter being obtained by hydrolysing cyanamide. Urea contains nearly 45 per cent. of nitrogen, compared with 15·5 per cent. in sodium nitrate, 20 per cent. in ammonium sulphate, and 35 per cent. in ammonium nitrate. According to MM. Matignon and Fréjacques, urea can be produced either continuously or discontinuously by heating ammonium carbamate in an autoclave to 150° C.; when the temperature has fallen to between 60° and 100° C., the resulting carbon dioxide and ammonia are drawn off and utilised again. Treated in this way 100 kg. of carbamate is said to yield 35 kg. of very pure urea that requires no further treatment.

Metallurgy.—The effect of the sudden depreciation of the mark has already been felt in the metallurgical market: French exports have diminished, and although Germany has great needs but cannot buy, she is once again in an ideal position for exportation. The French consumption of iron ore is satisfactory and the exports are directed mainly to Belgium and Luxembourg; Germany is now getting her supplies from Sweden as far as possible. Great attention is being paid by the industrial world to "reparations" and inter-Allied debts. The only hope of a solution seems to lie in the application of the Wiesbaden agreement and of its extension, the Le Trocquer scheme, which proposes payment in kind and the use of German labour and raw material to carry out important public works in France. Of these schemes the chief are the harnessing of the Rhône, the Truyère and the middle Dordogne, the construction of a tunnel between St. Maurice and Wesserling, and of a canal to connect the Sarre, Moselle, Meuse and Meuse-Scheldt. Apparently, the great French metallurgical companies are not hostile to this solution, but wish to find how their own interests would be affected before approving it. Meanwhile the industry has to face the problem of increased costs due to the rise in price of metallurgical coke. At the end of June the price of metallurgical coke was 90 francs per metric ton, but rose to 93 fr. in July and will probably reach 97 fr., whereas selling prices of metallurgical products are falling steadily. If the cost of labour and transport also increase the industry will be forced to sell at a loss and a repetition of the financial crisis of last year will have to be faced. One impediment to a solution is that, in certain regions, labour is not only scarce but expensive, and, in addition, a reduction in railway rates is badly needed. The question of an agreement between the chief metallurgical firms in Allied countries is still in suspense, the chief obstacle to a decision being the attitude of the Belgian producers. In the meantime the Union Financière and the Union Métallurgique have decided to co-operate in exporting metallurgical products and action will probably be taken when business is resumed after the holidays.

AUSTRALIA

Copper Mining in Papua

Negotiations between the Commonwealth Government and the New Guinea Copper Mines, Ltd., are stated to be practically complete for the purchase by the former of the company's jetty and the railway connecting the Dubuna mine with the coast. The company, which will undertake to raise £100,000 for developing this mine, will connect the Laloki mine with the coast by an aerial ropeway and instal smelters at Bootless Inlet. As the ore contains 40 per cent. of iron and 40 per cent. of sulphur, it may eventually be shipped to Australia for use as a flux for siliceous ores. When the copper smelters on the mainland can take delivery, about 3000 tons of ore per month will be shipped.—(*Ind. Austral.*, *May* 4, 1922.)

The New Guinea Copper Mines, Ltd., was formed to take over the property of the Laloki (Papua) Copper Mines Co., situated near Sapphire Creek, not far from Port Moresby. The ore developed down to the 200-ft. level in the Laloki and Dubuna mines is estimated at 300,000 t., averaging 4·8 to 5 per cent. copper, 42 per cent. sulphur, and 2½ dwt. gold and 10 dwt. silver per ton. At 100 ft. below the 200-ft. level the ore averages 7 per cent. copper and there is evidence of the existence of other valuable ore-bodies. A smelting-plant with a capacity of 300 t. of blister copper per month is being erected and as the ore is pyritic contracts have been made to sell it to manufacturers of sulphuric acid.—(*Mining Mag.*, *July*, 1922.)

CANADA

The Asbestos Industry

The recent agitation for the provincial Government of Quebec to impose an embargo upon the export of raw asbestos has apparently died a natural death. The United States is the largest consumer of raw asbestos, which enters that country duty free, but there is a prohibitive tariff on manufactured asbestos products. The falling off in the demand for asbestos is reflected by the restricted mining operations in the Eastern Townships of Quebec. The prices of fibre have dropped from 25 to 60 per cent., and the competition from South Africa has cut into the sale of Canadian fibre in Europe. The South African mines have a much lower wage-scale. Russian fibre is also appearing on the market. Under present and prospective trade conditions some of the lower-grade mines may have to close, and the industry as a whole will have to be prepared to meet the competitive conditions of ten years ago. This should not offer great difficulty as both mining and milling methods have been improved since that period and, with competent management, Canada should retain the firm grip which it has had upon the asbestos trade.

The Alcohol Industry

Notwithstanding restrictive legislation the distilleries of Canada apparently are not idle. According to the report of the Dominion Bureau of Statistics for 1920, there were four distilleries in operation during that year, viz., two in Ontario and one each in Quebec and British Columbia. Invested capital amounted to $11,773,046, salaries $84,345, wages $292,363, fuel costs $144,304, materials cost $1,210,633, and the value of products was $2,815,359. Exports of distilled liquor in 1919 were valued at $3,809,298, consisting of 1,455,707 galls., whilst in 1920 exports were 1,332,365 galls., valued at $3,042,307. Imports of distilled liquor in 1919 amounted to $426,201 and $2,815,359 in 1920. In the latter year 2,223,428 galls. of non-potable alcohol, valued at $1,595,584, was imported, compared with 651,396 galls., valued at $227,988, in 1919. The production of distilled liquors in 1920 showed an increased value of $2,389,158 over the preceding year. Both potable and non-potable alcohol show a greater output in 1920; potable spirits increased in quantity from 95,226 to 1,084,213 proof galls., whilst non-potable alcohol manufactured in 1920 amounted to 2,223,438, as against 651,396 proof galls. in 1919.

Miscellanea

The Duffee Soap Co. is to erect a factory at Streetville, Ont., for the manufacture of soaps, and the B. and I. Laboratories Co. a plant for the manufacture of washing powders in Hull, Que.

The National Silk Dyeing Co., of Paterson, N.J., has purchased 13 acres of land at Drummondville, Que., for the erection of its Canadian plant.

The Quebec Legislature has passed a Bill empowering the interests which control the supply of electric power to Montreal to develop the great water-power at Carillon Rapids upon the Ottawa River, between Ottawa and Montreal. The associated companies (Montreal Railway, Heat, Light and Power Co. and Quebec Railway, Light, Heat and Power Co.) now control immense hydro-electric properties in the province and developments are awaited with much interest.

UNITED STATES

Zinc Production in 1921

The output of zinc in the United States in 1921 was 218,073 tons, valued at $21,807,000, compared with 484,748 t., valued at $78,529,000, in the previous year; consumption fell from 323,043 t. to 203,600 t., and the number of retorts in operation at the end of the year was 42,400, a decrease of 13,600. The output of rolled zinc diminished by nearly one-half. Imports, which have been negligible since 1915, increased very considerably.—(*Schweiz. Chem.-Z., May* 30, 1922.)

The Dye Embargo

During the discussion in committee on the tariff Bill, the Senate rejected the clause extending the embargo on dyestuffs for one year after the Bill becomes law. This rejection is believed by representatives of the dye and chemical industries to be due to the Government's action in demanding the return of the German patents sold by the Alien Property Custodian to the Chemical Foundation (*cf.* J., 1922, 311 R). An attempt will be made, however, to reverse the decision when the Bill comes before the Senate proper after the committee stage is passed.—(*Oil, Paint and Drug Rep., July* 24, 1922.)

BRITISH INDIA

Glue Manufacture in Madras

The manufacture of glue on a commercial scale has been started at the experimental glue factory in Madras, and the output is about 2 cwt. per day of excellent glue, priced at 55 rupees per cwt. at the factory. Glue of special quality can be manufactured to meet specific requirements.

Preparation of Odourless Spirit

Ordinary rectified spirit possesses, besides the smell of alcohol, an odour characteristic of the raw material used in its manufacture. As spirit possessing this extraneous odour is objectionable for use in preparing perfumery, Prof. A. C. Sircar and S. C. Deb have worked out three methods for deodorising rectified spirit obtained from *mahua* flowers or molasses. The methods used were, briefly, as follows:—(1) Four c.c. of a solution of 12 g. of potassium permanganate in 100 c.c. of water was added to 1 litre of the spirit and the mixture kept for two days. The alcohol was decanted from the black precipitate that had formed, kept over quicklime overnight, and then distilled. Recovery of alcohol was about 85 to 90 per cent. by volume, and the sample had a sp. gr. of 0·788 at 33° C.; a sample of odourless ("silent") spirit had a sp. gr. of 0·794. (2) One litre of alcohol to which 10 g. of caustic potash had been added was kept overnight, boiled under a reflux condenser for 1 hr. next day, then distilled, kept overnight over quicklime, and finally re-distilled. The recovery was about 88 per cent. by volume. (3) A 250 c.c. sample was filtered 8 times through 4 g. of porous charcoal made from flax stems, and then through 4 g. of purified animal charcoal. The specific gravity of the product was 0·82. Samples were examined by the Industrial Chemist to the United Provinces and found to satisfy the requirements of a "silent" spirit and to compare favourably with foreign samples.—(*J. Ind. Indust., May*, 1922.)

GENERAL

The Rubber Research Association

The new laboratories of the Research Association of British Rubber and Tyre Manufacturers at Croydon were opened on July 26 by Lord Colwyn in the presence of a representative gathering. Lord Colwyn, in declaring the laboratories open, observed that the ability of the industry to compete in the world's markets depended largely upon research, and Mr. A. Johnston, of the North British Rubber Co., who presided, said that although the value of the world's output of rubber goods was £350,000,000, the industry might still be regarded as in its infancy; he was confident that both the producing and manufacturing branches of the industry would soon regain their former prosperity. The new laboratories, which are under the charge of Mr. B. D. Porritt, contain, in addition to administrative offices and a library, laboratories for physical, chemical and special work, a miniature factory equipped with machinery for preparing and vulcanising rubber, a mechanical testing-room, a workshop, etc. The site is conveniently situated and there is ample space for future extensions.

Consumption of Rubber

The excess of imports over exports of rubber in the chief consuming countries was as follows in 1913, 1920 and 1921:—

	1913	1920	1921
		Metric tons	
United States ..	53,092	264,962	191,700
England	27,315	61,398	45,514
Germany	16,525	12,095	20,756
France	5,751	16,031	15,064
Japan	1,265	5,858	22,500
Canada	2,116	12,035	9,000
Italy	2,546	6,222	5,000
Belgium	3,588	3,500	3,000
Sweden	1,039	1,592	826
Norway	338	245	193
Denmark	130	508	258

As is well known, the United States is the greatest user of raw rubber, and of the goods manufactured therewith about 70 per cent. consists of tyres, 14 per cent. of footwear, 10 per cent. of technical products and 6 per cent. of miscellaneous goods. The demand from Russia, which was about 11,600 t. in 1913, fell to only 500 t. in 1920. Imports of raw rubber into Germany during the 10 months ended February, 1922, exceeded the total imports in 1913.

Standard Dimensions of Iron Pipe Fittings

The British Engineering Standards Association has issued two new reports, No. 143, and No. 154, which set out the British standard dimensions for malleable and soft cast-iron pipe fittings of nominal sizes from ⅛ in. to 4 in. and suitable for steam, water and gas. Both of the reports contain details of special sizes of reducing fittings, definitions of screw threads, methods of specifying outlets, and tables of dimensions of standard equal and reducing fittings as well as special tables for ascertaining the centre-to-face dimensions of reducing fittings. Type drawings of the fittings are given, in addition to a diagram illustrating the method of setting out curves for reducing fittings. Report No. 143 is limited to fittings (bends, elbows, tees and crosses) designed for use where the maximum "delivery head" is needed and where the frictional resistance has to be considered, whereas No. 154 is devoted to all fittings in general use. The reports, priced at 1s. each, may be obtained from the offices of the Association, 28, Victoria Street, London, S.W. 1.

Silver and Tin in 1921

The following statistics of production, imports and exports have been compiled by the Imperial Mineral Resources Bureau:—

SILVER

			Fine oz.
United Kingdom	Imports	Silver bullion, unrefined	5,787,244
		Silver bullion, refined	40,245,164
		Silver coin, of legal tender in U.K. (Face, or currency value) ..	(£1,525,520)
		Silver coin, not cf legal tender in U.K. (Value of commodity) ..	(£1,303,454)
Northern Rhodesia	Production		8,866·71
Southern Rhodesia	Production		152,988·80
Union of S. Africa	Production	Silver in gold bullion ..	821,037·48
		Silver in other minerals	9,291·616
Canada ..	Production	Silver	13,134,926
	Exports	Silver in ore, concentrates, etc.	1,537,980
		Bullion	7,258,954
India ..	Imports		55,919,954
Australia ..	Production	In lead and zinc concentrates, in other ores and concentrates treated in Australia or exported and in gold bullion treated at Australian mints	8,326,006
		Refined silver produced in Australia, and metal in unrefined products, ore and concentrates exported	5,304,950
	Exports	Bar, ingot and sheet ..	2,711,729
		Silver contained in matte	58,860
		Silver contained in ores and concentrates ..	667,261
France ..	Imports	Beaten, drawn, rolled and thread	89,184
		Crude, in ingots ..	3,994,187·40
		Coin	368,889·10
	Exports	Beaten, drawn, rolled and thread	1,303,489·60
		Crude, in ingots ..	6,876,756·40
		Coin	1,626,693·55
Italy ..	Production	Ore	(0 long tons)
		Silver	199,330
Mexico ..	Production		64,465,347·45
United States	Production		50,364,389

TIN

			Long tons.
United Kingdom	Production	Cornwall only	700
	Imports		20,967
	Exports		9,900
Nigeria ..	Production	Ore	12,423
Southern Rhodesia	Production		4
Union of S. Africa	Production		1,408
		Metallic content ..	920
	Imports		124
	Exports		1,678
S.W. Africa Prot'c'te	Production	Ore	156
Swaziland	Production	Cassiterite	383
Federated Malay Sts.	Exports	Tin and tin contained in ore	34,489
India ..	Imports		2,656
	Exports	Ore	81
Australia ..	Production		2,650
		Refined tin produced in Australia, and metal in ore and concentrates exported	2,990
	Exports	Refined tin	1,704
		Tin in ore and concentrates exported ..	5
Belgium ..	Imports		1,731
France ..	Imports	Ore	358
		Metal	6,998
	Exports	Ore	27
		Metal	506
Germany ..	Imports	Ore	2,273
Norway ..	Imports	Crude metal	130
United States	Imports	Ore and oxide	13,696
		Bars, blocks, pig or granulated	24,197
	Exports	Pigs, bars, etc. ..	1,031
Bolivia ..	West Coast shipments	Ore	17,414
China ..	Production		8,500
Banka ..	Production		12,125
Billiton and Singkep	Production		7,000

Beet-Sugar Production in Europe

According to the Sugar Statistics Bureau Licht, of Magdeburg, the European production of beet sugar in the seasons 1920–21 and 1921–22 was as follows:—

	1920-21	1921-22
	Metric tons	
Germany	1,109,119	1,320,000
Czechoslovakia	713,165	650,000
France	336,960	300,000
Holland	317,196	335,000
Belgium	242,589	300,000
Austria	14,000	16,000
Hungary	33,000	52,000
Denmark	137,000	145,000
Sweden	182,458	253,000
Italy	138,000	230,000
Spain	238,000	118,000
Poland	171,000	205,000
Other countries	160,000	180,000
Total	3,792,487	4,104,000

The German beet-sugar industry is rapidly recovering, and it is anticipated that production for next season will increase by 500,000 metric tons. Beet cultivation in Holland and Belgium is increasing, Italy has changed from an importing to an exporting country, but the output of Czechoslovakia has fallen off and Poland can do little more than supply its own needs. As a result of the war France possessed only 80 beet-sugar factories at the beginning of the 1920–21 season, compared with 206 in 1913, and imports have risen from 115,057 t. in 1913 to 626,337 t. in 1920, the home consumption of refined sugar in a normal year exceeding 700,000 t. Many of the factories now under restoration are being equipped with modern plant; so that costs of production will eventually be lowered and the French sugar market strengthened. Apparently nothing has been done to restore the Russian beet-sugar industry; but the factories are believed to be intact.—(*U.S. Com. Rep., Apr.* 10, 1922.)

REPORTS

Annual Report of the Chief Inspector of Factories and Workshops, 1921. *Pp.* 131. *London: H.M. Stationery Office*, 1922. *Cmd.* 1705. *Price* 3*s. net.*

As the industrial situation throughout the past year has not encouraged trade developments, those developments which did take place are of particular interest. They include the introduction of a new type of gas-producing plant which yields an output equal to that of four ordinary producers but with reduced expenditure upon coal and labour, the erection of new steel rolling-mill plant and electric furnaces in Sheffield, and the production of a stainless steel which is ductile and can be worked cold into articles of intricate shape. The introduction of an untarnishable metal resembling electro-plate and described as synthetic silver-nickel is also mentioned. Grinding operations in the cutlery trade have also been greatly improved and new factories have been erected for the manufacture of plate-glass, matches, formic acid, hydrogen peroxide, lanoline from wool grease, and cement, and for refining edible oils. The only trades which have been fully occupied are those connected with the manufacture of food, confectionery, hosiery and high-class cloth. Of late, however, manufacturers have reported that, with orders for both home and foreign markets coming in, the outlook is brighter. Further progress has been made in the standardisation of safety precautions in certain industries. The Inspectors in the Engineering Branch have conducted special inquiries in connexion with the draft codes of regulations for chemical works, the manufacture of aerated waters, india rubber, and electric accumulators, and the handling of hides and skins. Other inquiries have related to the dangers incident to repairs to oil-tank steamers, the competency of certain persons to examine steam boilers, and explosions due to dust, metallic powders, and volatile substances. Revised pamphlets describing the dangers from carbon-monoxide poisoning and from the use of acetylene have been issued. Amongst new Orders and Regulations made during the year are those relating to the manufacture of lead compounds, aerated waters, and celluloid. The Departmental Committee on the Prevention of Anthrax has reported that the process devised for disinfecting wool is also suitable for disinfecting horsehair. Another committee is re-examining the question of the danger of the use of lead paints.

The number of registered factories during 1921 was 142,749, an increase of 2685 over the previous year; the number of workshops was 156,123, 4944 fewer than in 1920. The number of reported accidents was 92,565, of which 951 were fatal. The remarkable decrease in the number of accidents reported is almost entirely due to inactivity in industry. The statistics reveal a striking proportion of accidents due to "falling bodies" and to "persons falling." Detailed descriptions are given of a number of accidents arising from mechanical appliances and additional precautions suggested. Two dust explosions resulted in accidents during the year, one of metallic aluminium powder in a rotary sieving machine and the other of dust in the hopper under the rolls of a malt mill. Both were probably caused by sparks from foreign bodies admitted to the mechanism. A fatal accident resulted from the explosion of a mixture of copper oxide and a powdered aluminium alloy containing copper and zinc. The ignition was started by sparks falling from a crucible, and the violence of the explosion may have been due to the presence of ammonium nitrate as an impurity in the powder or to overheating in a preparatory drying process. In the chapters on Dangerous Trades, Health and Sanitation, and Welfare, reference is repeatedly made to the importance of cleanliness and of efficient ventilation.

During the year there were 230 cases of lead poisoning, 1 of arsenic poisoning, 1 of toxic jaundice caused by arseniuretted hydrogen, 32 of epitheliomatous ulceration, 29 of chrome ulceration, and 25 of anthrax. No cases of phosphorus or mercury poisoning were reported. In connexion with lead poisoning attention is directed to the risks run in cutting up painted steel plates by means of the oxy-acetylene flame on account of the volatilisation of lead. Men employed in cutting up galvanised plates were found to be suffering from "brassfounder's ague" due to the presence of zinc oxide in the fume evolved. There were 77 cases of carbon-monoxide poisoning; in the treatment of these cases there is still difficulty in making rescuers understand the importance of rest. The results are recorded of medical investigations of illness caused by naphtha fumes, aniline, and paranitraniline. Three of the cases of epitheliomatous ulceration among tar workers occurred in stokers exposed to fumes on the top of gas-producer plants to which coal was being charged.

The report includes separate chapters of general interest devoted to the Generation and Use of Electricity, Employment, Truck, Underground Workrooms, and Conditions in the Glass Industry.

Report on the Commercial and Financial Situation in Bulgaria, Dated January, 1922. *By* F. J. R. Rodd, *Late H.M. Commercial Secretary, Sofia. Department of Overseas Trade. Pp.* 13. *London: H.M. Stationery Office,* 1922. *Price* 6*d.*

It is anticipated that when statistics of the trade of Bulgaria during 1921 become available they will show an adverse trade balance, as they have done since 1908, except in the war years 1915, 1916, and 1917. The Bulgarian Government has been unable to negotiate either a foreign or an internal loan since the armistice, and the financial position is accordingly poor. Conditions have been unfavourable to importers of foreign goods, especially from countries with an appreciated currency. Thus Czech, German and Italian firms have secured much business and the contract for supplying copper sulphate to the Agricultural Bank, which had always been given to a British firm, has gone to Italy. There is little hope of improving the Bulgarian market for British goods, but a certain volume of trade, especially through Government contracts, will continue. Exports were fairly satisfactory, and would have been better but for the restrictions on exports of grain and timber. The rose-oil crop was good, and although the tobacco crop was 40 per cent. below the 1920 harvest, export was satisfactory. No important industrial developments have taken place, and the mineral resources remain entirely undeveloped, the only output of importance coming from the State coal mines, which produced 732,671 tons in 1920 and 397,496 t. during the first half of 1921. The few Bulgarian industries have not done well, largely owing to excessive taxation and to Government intervention.

Report on the Commercial and Industrial Situation of Hungary, Dated March, 1922. *By* R. J. E. Humphreys, *H.M. Commercial Secretary, Budapest. Department of Overseas Trade. Pp.* 38. *London: H.M. Stationery Office,* 1922. *Price* 1*s.*

Although Hungary is handicapped by heavy debts, an adverse trade balance and a greatly depreciated and unstable currency, it has passed through the critical period of 1921 remarkably well and much improvement is observable in comparison with 1920. Owing to the drought, the fodder, beet and potato crops were poor, but the cereal crops were above the average and high export prices were realised. Of the industries based on agriculture, the milling industry, able to grind 750,000 tons of cereals annually, worked well below capacity, and although the 16 beet-sugar factories can produce 245,000 t. of sugar per annum, the poor harvest made it necessary to import sugar from Czechoslovakia. Alcohol is now being exported, the production exceeding the demand. Coal-mining, which follows agriculture in order of importance, made progress in 1921 and only 650,000 t. out of the 6,756,622 t. consumed had to be imported; with one exception (Pecs), the Hungarian mines produce only brown coal, so that some importation is essential. Mining other than coal-mining does not exist in Hungary, and all the iron ore required in the large iron and steel industry is imported; this industry is now stagnant and development is unlikely until iron ore can be imported freely (*cf.* J., 1921, 279 R). A revival in the leather industry is expected and several new factories are being built.

Imports during 1921 amounted to 2,330,000 metric tons, an increase of 300 per cent. over the previous year, and included over 72 per cent. of manufactured articles, the chief of which were valued as follows (million korona):—Mineral oil, refined, 664·7; pharmaceutical articles, perfumes, 97·4; candles, soap, 44·8; fuel 180·4; chemicals 383·3; glassware 511·5; stoneware 202·3. The value of the korona, 10d. at par, fluctuated between 0·28d. and 0·8d. in 1921. The imports came, as in pre-war times, mainly from Austria, Czechoslovakia and Germany, and only to a small extent (about £300,000 worth) from Great Britain, although British goods are included in the imports from Austria. All kinds of manufactures—textiles, leather, iron and steel, glassware—are required by Hungary, but trade cannot be re-established so long as the Succession States adhere to their policy of restrictions and until transport is greatly improved. Exports, amounting to 840,000 t., or 60 per cent. more than in 1920, consisted almost entirely of agricultural products.

Report on Economic Conditions in Rumania, Revised to April, 1922. *By* A. Adams, *H.M. Commercial Secretary, Bucarest. Department of Overseas Trade. Pp.* 62. *London: H.M. Stationery Office,* 1922. *Price* 2*s.*

The industrial situation of Rumania has changed very little since the last report was issued (*cf.* J., 1921, 412 R), but a new customs tariff has been introduced which aims at protecting local industries. Cereal crops suffered from drought during 1921 and the yields of wheat and maize were low; probably wheat growing will diminish because the land has been subdivided among peasant owners. Apart from agriculture, petroleum production is the chief industry, the output in 1921 amounting to 1,163,780 tons from 690 wells, as compared with 1,034,123 t. in 1920 and 1,885,225 t. in 1913. About 70 per cent. of the output is sold locally at very low prices and as the depreciated exchange neutralises the benefit of high export prices, the development of the industry is handicapped by lack of capital. Production is not likely to increase owing to deficiencies in transport by both pipe-line and rail and to heavy export duties. A detailed account of the petroleum industry is given in an appendix.

Coal is mined chiefly in the Lower Carpathians and the output, now about 150,000 t. per month, is not large. About 350,000 t. of industrial coal and coke was imported before the war, principally from the United Kingdom, but importation has now practically ceased and the consumption of fuel oil is increasing as a consequence. In view of the application of protective duties, it is suggested that British manufacturers should start producing in the country. There are nearly 18 million inhabitants and the purchasing power of the population already shows signs of increasing. Detailed statistics of

Rumanian trade during 1921 are not available, but it is probable that there was a large adverse trade balance. During the year United Kingdom exports of manufactures to Rumania were valued at £5,432,855 and imports from Rumania at £3,359,386. The export trade of Rumania is hampered by transport deficiencies and the import trade by wide fluctuations in the value of the currency.

PARLIAMENTARY NEWS

House of Commons

Trusts and Combines

Sir W. Mitchell-Thomson, replying to Mr. Waterson, said that the subject of trusts and combines was still under consideration, but no undertaking to introduce legislation could be given.—(July 20.)

Cocaine

In a written answer Mr. Shortt informed Dr. McDonald that licensed importers of cocaine had to keep records of their sales for inspection. The records did not show how the drug was distributed, as it might pass through several hands before being used.—(July 24.)

Poison Gas

The Prime Minister informed Mr. L. Malone that the United States War Department had discontinued the manufacture of poison gas for equipping the U.S. Army for gas warfare, but Congress had sanctioned the continuation of research and experimental work on poison gas. The proposed expenditure on preparing gas-warfare in this country in 1922-23 was £169,700, which covered research on protective measures against gas attack. Except small quantities for the research work, no poison gas had been manufactured in this country since the Armistice.—(July 24.)

Replying to Mr. Foot, Sir R. Sanders said that eight full-time and four part-time employees were engaged in the preparation of, or research on, poison gas, at an estimated total cost of £8000, not including the staff and expenditure for research on protection against gas attack.—(Aug. 4.)

Duty on Nigerian Palm Kernels

Answering Dr. Murray, Mr. Churchill said that the average price of palm kernels in Lagos was about £11 per ton in May and the export duty £2 per ton, *i.e.*, about 18 per cent. of the average price at that time.—(July 25.)

British Dyestuffs Corporation

In answer to Rear-Admiral Adair, Sir W. Mitchell-Thomson said that he had seen an article on the dyestuff situation by Prof. H. E. Armstrong, suggesting that the Government should either withdraw its control of the Corporation or insist that the business should be managed by persons with technical qualifications. The Corporation was not controlled by the Government, whose interest in it was limited to a large holding of shares; he did not think it expedient to withdraw that interest. The proceedings at the last annual meeting showed that the directors were supported by the majority of the shareholders, and particularly those representing the important consuming interests.—(July 26.)

Coal Exports to the United States

Replying to Mr. W. Thorne, Mr. Bridgeman said that orders from the United States had caused an increase in the price of certain grades of coal and an appreciation of certain colliery shares, but he was not aware of any contract placed in South Wales by the American Shipping Board; neither did the orders from the United States amount to nearly as much as 500,000 tons.—(July 27.)

Benzol Production in the United Kingdom

Sir P. Lloyd-Greame observed, in answer to Mr. Kiley, that the quantity of benzol produced by members of the National Benzol Association during 1921 was estimated at 9 million gallons, whereas non-members produced about one-quarter of that amount. Owing to the coal stoppage production was greatly reduced during 1921, and the present normal output was about double that attained in that year.—(July 28.)

Prices of Lime Green

Answering Lieut.-Com. Kenworthy, Sir P. Lloyd-Greame said the National Federation of Paint, Varnish and Colour Manufacturers had informed him that whereas the German prices of the cheaper grades of lime green were about one-half those of equal grades of British make, the difference decreased as the quality improved, British and German prices approximating closely for the highest grade. As the Federation had informed the Dyestuffs Advisory Licensing Committee that the difference in price did not materially affect the cost of finished goods containing lime green, he did not propose to ask the Committee to reconsider its decision not to grant import licences for this colour.—(July 31.)

Dyestuffs Industry

Sir P. Lloyd-Greame stated, in reply to Mr. Galbraith, that proposals for assisting the dye-making industry as a whole by further co-operation of the dye-users and the State were being considered by the Board of Trade and the Chancellor of the Exchequer.—(July 31.)

Distinctive Colours for Poisons

In answer to Sir F. Flannery, Mr. Shortt said that the practicability of employing distinctive colours for poisons such as arsenic and strychnine was being inquired into.—(July 31.)

Australian Zinc Concentrates

Replying to Mr. D. Davies, Sir W. Mitchell-Thomson said the moment was inopportune for raising the question of determining the contracts for future deliveries of Australian zinc concentrates. The estimated loss per ton on concentrates delivered in this country during the six months ended June 30 was £3 14s. 8d.—(July 31, Aug. 4.)

Stocks of Lead and Spelter

Mr. Bridgeman informed Mr. D. Davis that stocks of pig lead in the metal-exchange warehouses amounted to 268 tons and of spelter to 4662 t. on June 30, including Government stocks of spelter; stocks were also held by private firms.—(July 31.)

Morphia

Answering Viscountess Astor Sir J. Baird stated that, in 1920, 643,985 oz. of morphine was manufactured in England and 322,464 oz. of morphine and heroin exported (excluding amounts exported by post or in preparations).—(Aug. 2.)

Imports of Cement

In a written answer to Lieut.-Col. J. Ward, Sir P. Lloyd-Greame gave the imports of cement in 1920, 1921 and the first half of 1922 as 38,438 tons, 105,711 t., and 60,264 t., respectively.—(Aug. 3.)

Milk and Dairies (Amendment) Bill

The object of this Bill is to postpone until 1925 the operation of the Milk and Dairies Act, passed in 1915 and due to come in force on September 1, 1922, and to ensure the sale of clean milk. Thus Clause 4 prohibits the addition of water, colouring matter, or any dried or condensed milk or any fluid econstituted therefrom, to milk, including skimmed nd separated milk, intended for sale. Clause 5 prohibits the sale of milk from a cow suffering with a tuberculous udder and Clause 8 enables the Minister of Health to make Regulations for preventing danger to health from imported milk. In moving the second reading, Sir A. Mond said that he was considering methods of grading milk; the question of the standard of condensed milk was one of food value, but a standard such as a bacterio-ogical count might be laid down.

Smoke Abatement Bill

This Bill proposes to amend the law relating to smoke nuisances by providing increased penalties for the emission of smoke, even if not black smoke, and of soot, ash, grit, and gritty particles from chimneys, not including those of private dwelling-houses. In proceedings for smoke nuisance, proof that the best practicable means was used for preventing the nuisance constitutes a defence. Power is given to the Minister of Health to extend, after consultation with the local authorities or other interests, the list of noxious or offensive gases and of works mentioned in the Alkali, etc. Works Regulation Act, 1906. Local authorities are empowered to require new buildings other than private dwelling-houses to be provided with heating arrangements calculated to prevent or reduce the emission of smoke. Two or more local authorities may combine to carry out their duties in respect of smoke nuisances and if a local authority fails to carry out these duties, the Minister may order the county council to carry them out.

Safeguarding of Industries Act

Order No. 1 *under Part II.*—In presenting the draft Order proposed to be made under Part II of the Act (*cf.* this issue, p. 339 R) Mr. Baldwin said that he had declined to make the Order apply to glassware from Czechoslovakia, as that country was making such efforts to stabilise its currency that any bounty it now derived from depreciation of the currency would soon cease. Amendments proposing to exclude glassware and hollow-ware from the Order on the ground that although German currency had depreciated, imports from that country had declined instead of increasing, were defeated. The Order was approved by 152 votes to 47.—(July 31.)

The following are summaries of answers given by the President of the Board of Trade to questions relating to the operation of the Act:—

Orders under Part II.—Action will be taken as rapidly as possible on any reports that may be received from Committees, but any Orders so made require confirmation.—(July 24.)

Glassware.—Evidence was given in public before the Committee on glassware that unemployment was being caused by importations of glassware, but it cannot be published for reasons of economy. The Board of Trade has no information suggesting that the imposition of a duty (under Part II) on German glassware would transfer the trade from Germany to Czechoslovakia. Glass jugs and tumblers are neither scientific glassware nor lamp-blown ware, and accordingly are not dutiable. Blanks for measure glasses are not held as dutiable, although glass articles such as pipettes and burettes, even when ungraduated, are still dutiable as scientific glassware or lamp-blown ware.—(July 24.)

Complaints.—Five complaints alleging dumping in the sense of Section 2 (1) (*a*) have been received since Part II came into force in August, 1921. Of these complaints, two have been referred to Committees, one was rejected, and two were referred back for further information.—(July 24.)

New Industries.—Since the Act came into operation the range of production of the branches of the chemical industry covered by the last heading of the Schedule has greatly developed and distinct progress is being made in respect of scientific glassware and optical and scientific instruments. There is no doubt that the Act has encouraged some manufacturers to keep in operation works that would otherwise have been closed down.—(July 24.)

"R" Commodities.—The Referee's judgment in the sodium hyposulphite case did not suggest that the exact scope and meaning of "R" should be defined in general, but that a more definite meaning was required in this particular case.—(July 24.)

Scheduled Articles.—One item has been added and seven removed from the list by direction of the Referee, and in consequence of the Referee's awards, 24 items have, on the responsibility of the Board of Trade, been deleted and the standard of the dutiable grade of 10 other scheduled chemicals has been raised. In nine complaints the Board's action was upheld by the Referee.—(July 24.)

Vulcanised Fibre.—No representations have been received from manufacturers of electrical apparatus that they depend on America for supplies of special qualities of vulcanised fibre.—(July 24.)

Gas Mantles.—The duty collected on dutiable ingredients of incandescent gas mantles up to July 1 amounts to £232. The Referee's award was not signed until May 17.—(July 25.)

Purity of Scheduled Chemicals.—Purity is not the only criterion used in deciding whether a chemical comes within the scope of Part I of the Act or not, as was shown by the Referee in deciding the sodium-hyposulphite case.—(July 31.)

Analytical Reagents.—Heavy chemicals are dutiable only when prepared in a state of special purity for use as analytical reagents.—(July 31.)

Sodium Pyrophosphate.—The Board of Trade is unaware that the Referee's decision respecting sodium pyrophosphate has injured the export trade of any company or has curtailed output and caused unemployment.—(July 31.)

Upon the adjournment of the House until November 14, the Royal Assent was reported to the Electricity (Supply) Act, 1922, and to the Milk and Dairies (Amendment) Act, 1922.

COMPANY NEWS

Mond Nickel Co.—The eighth annual meeting was held in London on July 26, and Mr. R. Mond, who presided, said that the consumption of nickel for peace purposes had not yet attained the pre-war level. The outlook was not reassuring, but as trade revived prospects would improve, especially as new uses of the metal or its alloys were constantly being discovered and no efforts were spared in investigating new outlets. The nickel coinage adopted in Canada and Italy had proved so satisfactory that its use had been extended and it had also been adopted in other countries. With a view to extending the use of nickel the company had participated in the formation of the American Nickel Corporation, of Clearfield, Pa., which supplied malleable nickel to manufacturers of nickel goods and had been appointed the company's representative for the sale of raw nickel in the United States. Sales of copper sulphate had been almost normal in quantity, but the price had been kept low; and sales of precious metals had also been well maintained. Costs of production, though lower, were still too high, but no effort would be spared to maintain the company's strong position in the nickel industry.

The taxation problems of the company have not been finally settled, but figures are now available to show the financial position for the two years ended April 30, 1922. The profits for 1921 and 1922 were £222,630 and £299,041, respectively, and £610,383 (including £114,794 brought forward from 1920) remains for distribution; £220,000 was allocated for dividends paid for 1921 and an interim dividend of £110,000 on the preference and ordinary capital has been paid. A further sum of £87,500 is to be paid in dividends on the preference capital to make up the dividend to 7 per cent. for the year and £45,000 (1s. per share) on the ordinary capital, making a total for 1922 of £242,500; £110,000 has been provided for income-tax and £37,883 carried forward.

Anglo-Continental Guano Works, Ltd.—At the fifth ordinary general meeting, held on July 26, Mr. J. S. Holmes, who presided, said that the demand for fertilisers in the spring of 1921 was good both in the United Kingdom and in Europe, but the summer drought reduced the consumption, and Belgian and French makers of superphosphate, aided by the depreciated value of the franc, attempted to find a market in this country. Consequently, prices fell steadily, buyers were waiting until prices ceased to fall, and trade in the autumn was very poor, so that the total output of all the company's factories decreased greatly. Despite foreign competition, the demand was much better in 1922 and all the old stocks were cleared. Prices had been adjusted more closely to the foreign level, and if they remained stable an increased volume of trade should result in the winter. The profit from last year's trading was £32,364, which with a carry-forward of £9666, made a total of £42,030. The dividend on the preference shares absorbed £22,500 and that on the ordinary shares £14,000 (5 per cent.), leaving a balance of £5530.

OFFICIAL TRADE INTELLIGENCE

(*From the Board of Trade Journal for July 27 and August 3*)

OPENINGS FOR BRITISH TRADE

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence), 35, Old Queen Street, London, S.W. 1, from firms, agents or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of Firm or Agent	Materials	Reference Number
Belgium	Iron, steel, cement	122
"	Steel, pig iron	123
Canada	Pottery	87
"	Drugs	121
Colombia	Paper	116
Denmark	Heavy chemicals	94
"	Tinplate, blackplate	95
"	Iron, metals in ingots	96
France	Oils, tallow, chemicals, sugar	125
Holland	Chemicals (tender for)	16376/F.W./G.P.
Hungary	Rubber goods, drugs	103
New Zealand	Tinplate, galvanised sheets, steel, crockery	88
"	Sodium sulphide, cream of tartar, tartaric and citric acids, chemicals for druggists, refrigerating works, fell-mongers and hide buyers, paper	89
Paraguay	Glass, glassware, pottery	225/84/F.G./M.C.
Sweden	Glass, glassware, pottery	225/1/F.G./M.C.
Switzerland	Copper sulphate, turpentine, linseed oil	111
"	Sugar, syrup	112

TARIFF CUSTOMS EXCISE

Bechuanaland, etc.—Proclamations have been issued restricting the importation into Bechuanaland, Basutoland and Swaziland of opium and other habit-forming drugs.

British India.—The tariff valuations for sulphur have been revised.

French W. Africa.—The "coefficients of increase" applied to imports of alcohol, potable spirits, alcoholic perfumery, etc. have been reduced from 2·5 to 1·5, the other "coefficients" remaining unchanged.

Germany.—A law has been passed authorising the reduction or suspension of the import duties under certain conditions. Cocoa products have been added to the export free-list.

Gold Coast.—Pharmacopœial preparations imported by medical practitioners and registered druggists are exempted from duty.

Greece.—Increased import duties have been applied to cocoa, vegetable oils, and plate glass, but those on coal-tar dyes, groundnut oil, ethers, etc. have been reduced. It is proposed to prohibit the importation for six months of certain cacao products and wares of glass.

Hungary.—From July 25 the surcharge when import duties on goods (not specified in lists "A," "B," and "C") are paid in paper currency has been fixed at 19,900 per cent., *i.e.*, 200 times the nominal rates. The surcharges on goods in lists "A," "B," and "C" amount to 12, 40, and 80 times the nominal rates, respectively.

Italy.—The "coefficient of increase" applied to the duty on sugar that yields more than 94 per cent. on refining has been reduced from 1 to 0·7, *i.e.*, the duty is reduced from 36 to 30·60 gold lire per 100 kg.

Norway.—Alterations in the customs tariff affect porcelain insulators, plate and sheet-glass (not including polished, bevelled, etc. glass or photographic plates), and iron sheets.

Rumania.—Importers of pharmaceutical products must show that the sale and manufacture of such products is sanctioned in the country of origin, furnish a certificate of their chemical composition, and state their therapeutic properties.

Sierra Leone.—The differential export duty on palm kernels has been abolished.

South Africa.—It is proposed to increase the customs duties on corks and stoppers made of mineral or vegetable material and on starch; to abolish the duty on scientific apparatus, glassware and porcelain made in the United Kingdom and reciprocating British Possessions; and to admit borax, boric acid, bromine, litharge, manganese dioxide, etc. duty free. Rebates of the duty on "plain spirits" are also proposed.

Switzerland.—All goods except scrap iron, and unmanufactured and coined gold may be exported under general licence. The restrictions on the importation of goods have been continued in force until June 30, 1923.

Tanganyika Territory.—The export duty on hides has been suspended until December 31. The prohibition of the importation of dyestuffs has been removed.

Trinidad.—Explosives (other than for industrial use), cocaine and opium may not be exported.

Tripolitania.—Import taxes are to be applied to alcohol, spirituous essences, sugar, and groundnuts.

United States.—The amendments adopted by the Senate to the Tariff Revision Bill are given in the issue for July 27.

GOVERNMENT ORDERS AND NOTICES

Safeguarding of Industries Act.—*Part I.*—In accordance with the Referee's judgment on the complaint relating to sodium hyposulphite, the Board of Trade has amended the lists of dutiable articles as follows:—For "R. Sodium hyposulphite" read "Sodium hyposulphite (photographic quality)." For "R. Sodium thiosulphate" read "Sodium thiosulphate (photographic quality)."

Part II.—The Board of Trade has issued the Safeguarding of Industries (No. 1) Order, 1922, under Part II of the Act. The Order, which came into force on August 8, imposes a duty of 33⅓ per cent. on, *inter alia*, unmounted domestic glassware, illuminating glassware (not including electric-lamp bulbs, miners' lamp glasses, oil-lamp chimneys, pressed glassware, or articles made of fused silica, vitresoil or similar material), and domestic hollow-ware made of aluminium, or of steel or wrought iron, enamelled.

The committee appointed to inquire into complaints relating to glass bottles made in Holland and Germany has reported that the conditions laid down in Section 2 (1) of the Act are not fulfilled. Consequently the Board of Trade can take no further action in respect of the complaints.

Industrial Property in Luxembourg.—In consequence of the accession of Luxembourg to the International Convention for the Protection of Industrial Property, an Order in Council has been made, applying the provisions of Section 91 of the Patents and Designs Act, 1907, as amended in 1914 and 1919, to Luxembourg from June 30. A copy of the Order may be consulted in the Patent Office Library, 25, Southampton Buildings, London, W.C. 2.

TRADE NOTES

BRITISH

Canadian Exports

According to the returns of the Department of Trade and Commerce, Canada leads the world in the value of exports per head of population. The returns show that Canada's exports now amount, in value, to $150 *per capita*, as compared with $65 for the United States and $98 for the United Kingdom.

The exported value of Canadian products for the fiscal year ending March 31, 1922, was $740,240,680, a decrease of almost 450 millions as compared with the preceding 12 months. The shrinkage, however, has been in value rather than in volume. The exports of paper and pulp make a useful illustration. In the fiscal year 1921, 14,363,006 cwt. of pulp, valued at $71,552,037, whilst in 1922, 12,435,238 cwt., valued at $35,924,877, were exported. The volume declined about one-seventh and the value about one-half. The export of newsprint in 1921 was 15,112,586 cwt., valued at $78,923,137, whilst in 1922 there was a slight increase to 15,138,328 cwt., valued at $64,635,627, or a shrinkage exceeding 14 million dollars. Agricultural products exhibit the same shrinkage in value, but an increased volume in many items.

FOREIGN

Imports of Chemicals into Lithuania

During 1921 Lithuania imported chemicals valued at 21,004,976 German marks, lubricating oil valued at 12,300,163 mk., and petroleum to the value of 15,366,530 mk.

German Trade in Colours, Oils and Fats

The extent to which the exports of colours, oils and fats from Germany have declined since the war can be seen from the following table, in which the exports are shown in 1000 metric tons and millions of marks:—

	1913		1920		1921 May-Dec.	
	1000 m. tons	Mill. mk.	1000 m. tons	Mill. mk.	1000 m. tons	Mill. mk.
Colours and colouring materials	262	272·9	101·5	3682·7	68·2	2505·6
Varnish lacquers, mastic	6·6	5·3	2·5	46·0	3·2	61·1
Mineral oils, etc. ..	117·9	8·3	25·8	82·0	25·3	91·9
Coal-tar, coal-tar oils, coal-tar products ..	259·2	32·1	67·7	207·7	149·9	348·1
Soap, candles, wax products	45·8	30·0	8·2	118·0	11·1	198·5

Statistics for the exports of colours during the first four months of 1921 are not available, but those for the rest of the year show an improvement compared with the previous year. Colours and colouring materials play an important part in the export trade, and in 1920 represented 5 per cent. of the total value of the exports, viz., 69·5 milliard paper marks. There was also a slight recovery in the exports of oils, fats, varnishes, lakes, etc. during 1921. Exports of varnish, lakes and similar products during the first quarter of 1922 were as follows:—Lac varnish, spirit-free, asphalt, and other lacquers, 1059·3 t., 46·4 mill. mk.; sealing wax, 41·5 t., 1·7 mill. mk.; spirit varnishes, 31·4 t., 2·4 mill. mk.; oil varnish, varnish salt, birdlime, 129·3 t., 3·5 mill. mk.; mastic, 79·2 t., 1·2 mill. mk.; indigo and indigo-carmine lakes, 3638 t., 330·7 mill. mk.; ultramarine lakes, 217·4 t., 14·1 mill. mk. The destinations of the two last categories are shown below:—

	Jan.–Mar., 1922	
	Indigo Lakes	Ultramarine Lakes
	Metric tons	
Austria	—	5·0
Denmark	—	7·9
England	—	6·6
Baltic	—	13·0
Balkan States	—	3·0
Holland	58·7	—
Italy	21·2	—
Spain	18·4	53·5
Turkey	6·6	—
N. Africa	74·9	—
E. Asia	2971·2	18·2
Dutch E. Indies, etc.	259·5	—
S. America	—	27·7
Other countries	227·5	82·5

Imports of these commodities also declined. Thus the imports of colours, etc. fell from 74,860 t. in 1913 to 11,500 t. in 1920 and 3740 t. in 1921; those of varnishes, lacquers and mastic fell from 3520 t. in 1913 to 790 t. in 1920 and 390 t. in 1921; those of oils, etc. from 41,602,160 t. in 1913 to 11,139,890 t. in 1920 and 8,830,650 t. in 1921, and of soap, candles, wax, etc. from 45,750 t. in 1913 to 41,190 t. in 1920 and 15,330 t. in 1921.

Spanish Export Trade in Turpentine and Resin

The provinces of Old Castille and Segovia are the chief producing centres of turpentine and resin in Spain. Exports in 1918, 1919, 1920, and during the first four months of 1921, were as follows:—

	1918	1919	1920	1921 Jan.–Apr.
	Metric tons.			
Turpentine:—				
Belgium	—	1,924	1,737	487
England	344	1,481	110	—
France	1,879	597	1,016	—
Morocco	0·3	0·5	0·5	—
Other countries	618	586	217	31
Pine-Tar:—				
England	—	18	62	—
Italy	7·3	10	231	—
Switzerland	578	809	9	—
Other countries	73	470	240	36
Resin:—				
Germany	—	—	873	338
Belgium	—	4,902	6,066	1,018
France	1,921	937	261	1·8
England	961	4,597	2,639	298
Portugal	104	28	0·7	—
Other countries	2,664	2,573	2,339	288

The industry is controlled by the Union Resinera Espanola, one of the most important trusts in Spain. Some time ago German capital was invested in the trust and the Industria Resinera Ruth was formed with a capital of 50 million pesetas, of which 70 per cent. was provided by the Union Resinera. The Ruth company, which owns 23 factories equipped with modern plant, will manufacture not only resin products but also fish and olive oils, varnish, lakes, driers, colours, linoleum, glue, aniline and other chemicals, including synthetic camphor.

REVIEWS

Catalytic Action. *By* Prof. K. George Falk. *Pp.* 172. *New York: Chemical Catalog Co., Inc.*, 1922. *Price* $2.50.

Catalysis has been the subject of not a few monographs recently, and one is tempted to anticipate some redundancy as additional books on this branch make their appearance. Prof. Falk's work, however, is to be heartily welcomed, because he deals with catalytic action on the basis of the simplest accepted principles of chemistry and examines the various current theories of catalysis from this standpoint, instead of considering each of the latter as more or less individual entities.

The result, even when one cannot perhaps accept the author's views in their entirety, is a very logical development of catalytic action, in which the relative importance of the subject itself and of the tentative theories put forward to account for it fall into due perspective with the fundamental principles of chemistry.

It is stated that the purpose of the book is to emphasise the *chemical nature* of so-called catalytic actions and that chemical (and also physical) relationships and laws which apply to chemical reactions necessarily must hold for catalytic actions.

The author's definition of the latter is an action in which the chemical composition of one of the final products of the action is the same as that of one of the initial substances: a formal statement of fact which has the advantage of being independent of the more involved "criteria" suggested by others.

An introductory chapter relates how the Berzelian classification of catalytic actions arose and sketches the history of the subject down to Ostwald's definitions of catalysis, with some stress on the manner in which, after Berzelius' time, this group of actions became rather the dumping-ground for chemical mysteries than a clear-cut subdivision.

Prof. Falk then applies his general "addition theory of chemical reactions" to catalysis; this postulates that the first step in a reaction is combination to form an addition compound. Hence he deals with catalysis in homogeneous systems from the viewpoint that the catalyst and reactants form an addition or intermediate compound, and with catalysis in heterogeneous systems on the basis that the first step is the formation of chemical compounds on the surface of the catalyst by the action of chemical forces.

The questions of mathematical expression of the rate of catalytic action, of the reaction velocity equations and of energy relations are then discussed, chiefly with reference to homogeneous systems, and subsequently enzyme action and contact catalyses are reviewed from the same standpoint.

Due restraint is shown in applying the ionic theory of electrolytic dissociation to action in aqueous media. The prevailing theories of electronic atomic structure, radiation, and adsorption (in Langmuir's sense, *i.e.*, as due to chemical force) receive adequate attention, especially in reference to catalytic action at the surface of living cells and porous solids.

As already indicated, one is impressed by the fact that, starting from simple definitely chemical premises, not only does catalysis appear as a simple special case of ordinary chemical action, but the physical and mathematical interpretation of the subject appears to be rendered more easy and more certain; moreover, it would seem unnecessary to restrict this method of approaching catalysis to the author's particular theory of the general mechanism of chemical reactions.

The general principles and arrangement of the work are thus entirely to be commended. The examples illustrating the development of the author's views, whilst on the whole well-chosen, might perhaps have been taken from a somewhat wider field; but this is, after all, largely a matter of personal opinion.

As regards catalysis in homogeneous systems, much stress is laid on Steiglitz's work on the hydrolysis of imino-esters, and it is shown that the results with imino-esters rather than with ordinary acid esters are more useful in the particular illustration in view. At the same time, one feels that the general argument would have been strengthened by appeal to a wider range of experimental work; and, perhaps, if no suitable data from American sources were available, it might have been well to scan the European literature more exhaustively than would appear to have been done!

Again, in dealing with contact catalysis, the only examples chosen from the very wide range of Sabatier's investigations are the decomposition of alcohols in presence of metals or metallic oxides and the similar decomposition of esters. The latter is a very complicated process with numerous possibilities of side-actions, and is not at the present stage sufficiently thoroughly investigated.

These minor points are mentioned only because it is felt that the general theory developed is worthy of even better exemplification that that which it has received, and not in any way in depreciation of the book. Professor Falk deserves the congratulations and thanks of chemists in general for his lucid, logical and straightforward exposition of his subject.

T. P. HILDITCH.

(1) A TEXT-BOOK OF ORGANIC CHEMISTRY. *By* A. BERNTHSEN. *New edition revised to date by* J. J. SUDBOROUGH. *Pp. xvi*+908. *London: Blackie and Son, Ltd.*, 1922. *Price* 12*s.* 6*d. net.* (2) DYES CLASSIFIED BY INTERMEDIATES. *By* R. NORRIS SHREVE. *Pp.* 631. *New York: The Chemical Catalog Co., Inc.*, 1922. *Price* $10 *net.*

(1) This revised edition of Bernthsen's well-known text-book is practically a new work. Although the arrangement is based on that of the older editions a great deal of extra material has been added, and Prof. Sudborough's claim that it has been brought up to date is fully justified. In addition to the incorporation of the results of recent research, new chapters have been added on the synthesis and degradation of ring systems, including a mention of spirans and cage systems, the organic compounds of arsenic, synthetic drugs, synthetic dyes and the chemistry of rubber. The thoroughness of treatment of the subject has, perhaps, rendered the book somewhat indigestible, but this seems nowadays an almost inevitable concomitant of works on organic chemistry. The laudable desire for compression has resulted in statements which may mislead a student by their brevity. For example, in dealing with the formation of diazonium compounds no mention is made of the fact that some primary amines do not diazotise readily at 0° C., nor is the influence of negative substituents described. Again, it is to be inferred that benz-antialdoxime does not react with acetic anhydride as readily as the syn-isomeride and that in the latter case the nitrile is the primary product of the reaction. Moreover, the statement that acids transform the anti- into the syn-oxime is much too brief, as this occurs only under very special conditions and dilute acids bring about the reverse change.

The book is well supplied with references, particularly to more recent work, and these enable the student interested in a special subject to extend his reading to the original papers, an advantage so often missing in elementary text-books. It is to be regretted, however, that these references are interpolated in the text and not put as footnotes as they militate considerably against the ease of reading of the book. The printing is clear, the paper good though somewhat transparent, and misprints rare. The price is unexpectedly low considering the bulk and get-up of the volume, and it is to be hoped that the period of inflation of prices of chemical books is coming to an end. Students of organic chemistry will find this book a very sound investment.

(2) This volume represents a new classification of dyestuffs which will probably be of great use to the manufacturer as showing the dyes which can be prepared from the intermediates he has at hand, together with some indication of the demand for these particular dyestuffs as shown by the quantities imported and manufactured in the United States. The intermediates are arranged in alphabetical order, their formulæ given and their chemical name or names, the synonyms being cross-indexed in their alphabetical order. Where available, statistics are supplied of the amounts imported or manufactured in the United States in recent years. The methods of preparation of the intermediate are briefly indicated, together with references, and there follows a table giving the dyes, listed in Schultz's Farbstofftabellen, 1914 edition, made from the particular intermediate, statistics of their import and manufacture in the United States, the other intermediates used in their manufacture, and the class of dye according to the method of application.

At the end of the volume is given a formula index of intermediates, a glossary of dye names and an index of Schultz numbers. The list of intermediates is fairly complete and the book represents the results of much painstaking labour, though it would seem to have been worth the extra trouble to have given references to the originals rather than to other reference books such as Lange's Zwischenprodukte, Ullmann's Enzyklopædie or Barnett's Anthracene, etc. A few misprints are observable, particularly in the form of dropped letters, but on the whole the work is very free from typographical errors; the print and formulæ are very clear and the get-up of the book excellent.

The English reader, though he may find the book of considerable use for reference, will be disappointed to find that even in the glossary of dye names but few of the current American and British trade names are given, probably owing to the difficulty of obtaining information on the composition of dyes supplied under such trade names. It is open to doubt whether the secretive policy of British firms as regards the chemical constitution of their products is in the interest of the development of the dye industry in this country.

O. L. Brady.

Dictionnaire Anglais - Français - Allemand de Mots et Locutions intéressant la Physique et la Chimie. *By* R. Cornubert. *Pp.* 297. *Paris: Dunod*, 1922. *Price, paper* 42 *fr., bound* 47 *fr.*

The object of this dictionary is to enable French scientists to read works on chemistry and physics written in German or English, and thus open to them a wider range of scientific literature than could be obtained by confining their studies to their own language. There is thus nothing novel about the purpose of the author, and the book has to stand or fall by comparison with other similar dictionaries. The requirements that such a book has to fulfil are that it must be accurate, it must be reasonably complete, and it must be conveniently arranged for ready reference. It is essentially in the matter of arrangement that this book differs from most others of the same kind.. It is not, as usual, in three parts; the author has arranged his vocabulary in three columns, in which the words in the respective languages are arranged in an alphabetical order applicable to all, a scheme which is generally possible, because the great majority of scientific terms are very much alike in all three languages; the words that run in true alphabetical order are printed in heavy type, equivalent words in the other languages that do not fall into this order being in ordinary type. For example, under the letter A we find Ausschalter in heavy type in the German column, the corresponding words in English and French, cut-out and interrupteur, being printed in ordinary type in their respective columns, all, however, under the letter A; in turn cut-out is to be found in heavy type in the English column under the letter C, and interrupteur in heavy type in the French column under the letter I. The author states that he has adopted this method in order to save space, which it undoubtedly does, and though it appears clumsy, it is quite possible that with practice the system might be found less inconvenient than it is in the hands of one not experienced in it.

On the score of completeness there is not much to be said; most of the ordinary words that are likely to occur in a work dealing with pure chemistry or pure physics are to be found. On the other hand, the far more difficult side, that of the applied sciences, is very imperfectly represented, whereas the names of minerals figure very largely, though these as a rule present very little difficulty.

It is mainly on the matter of accuracy that this dictionary affords ground for complaint, mistakes of all kinds being numerous. A few may be quoted at random: The German for pyrrhotite is given as Leberkies, whereas it should be Magnetkies; Leberkies is the name given to a variety of Marcasite. Raseneisenerz is incorrectly translated limonite, instead of bog ore. German silver is not the same thing as Constantan. Abraum salt is certainly not [illegible]ish, any more than is Amiant. A good example [illegible] careless work that disfigures this book is found in the translation of balance romaine as Sweedish (sic!) balance. It is obvious that this dictionary is anything but a trustworthy guide, and a work that will not stand this essential test cannot safely be recommended to the student.

REVIEW

Vol. XLI] AUGUST 31, 1922 [No. 16

THE COMPARATIVE SWEETNESS AND PRESERVING QUALITY OF CANE AND BEET SUGARS

JAMES P. OGILVIE

AT the present time various grades of white cane and beet sugar are sold on our market, and broadly these may be divided into (1) refined and (2) direct-consumption sugars. By a refined sugar is generally understood a product which is obtained by re-melting raw cane or beet sugar, passing the resulting liquor through animal charcoal to decolorise and purify it, and finally re-crystallising. Granulated and cube sugars so produced in refineries in this country are of a remarkable degree of purity, and their sucrose content generally reaches 99·95 per cent., the traces of moisture, ash, reducing sugars, and organic non-sugars which may be present being hardly capable of determination even by the application of special methods. (Intern. Sugar J., 1920, 654). It is conceded by all that there can be no difference in the sweetness or preserving quality of such a highly refined product (which is in effect pure sucrose), whether it is derived originally from the cane or the beet.

DESCRIPTION OF DIRECT-CONSUMPTION GRADES

The direct-consumption sugars, as the term suggests, are grades produced directly from the cane or the beet without the intermediary of the refinery, or the use of animal charcoal, of suitable purity for use on the table or for manufacturing purposes. They are made by liming and sulphiting or carbonating the juice, filtering the syrup or allowing it to subside, and washing the resulting crystals with water and steam in the centrifugal machine. The best grades of cane or beet sugar thus made have a sucrose content of about 99·5 per cent., are of good colour, and can very well be used for domestic purposes, though admittedly they do not possess as a rule the faultless appearance of the best refinery product. Excellent direct-consumption cane sugar is now being imported into this country (though as yet in comparatively small amount) from the British West Indies (a recent analysis gave, per cent. :—sucrose, 99·5 ; reducing sugars, 0·23 ; ash, 0·02 ; organic non-sugars, 0·15, and moisture 0·10) ; whilst as an example of a superior direct-consumption beet sugar may be mentioned the granulated sugar produced at the beet-sugar factories in this country during the last season (*cf.* J., 1922, 149–154 B, Kelham sugar giving the following figures : sucrose, 99·9 ; reducing sugars, absent ; ash, 0·01 ; organic non-sugars, 0·04 ; and moisture, 0·05 per cent. Cantley sugar is equally pure). Other grades of direct-consumption sugars are used in the United Kingdom in the jam, confectionery, biscuit, and condensed-milk industries, though these are often " off-colour," and therefore not in demand in the grocery trade.

These lower grade direct-consumption sugars have only a slightly smaller sucrose content than the refined article ; and the difference between them and pure sucrose is to be attributed to the small amount of impurities, such as reducing sugars, ash, and organic non-sugar matter (the last-named including traces of colouring and aromatic substances), which are occluded in the interstices between the lamellæ of the crystals. Direct-consumption cane sugars generally contain reducing sugars, and may possess a slightly acid reaction, whilst the trace of non-sugar substances which they contain imparts a faintly pleasant flavour derived from the original juice. On the other hand, beet sugars normally do not contain reducing sugars, and in the case of the lower grades their solutions may be slightly alkaline. Further, the inferior grades of white beet sugars, such as the so-called "washed crystals," may still retain a trace of the objectionable (almost nauseous) flavour that is so characteristic of the juice from which they are extracted. Then in this description of direct-consumption grades mention may be made of the palatable and wholesome West Indian yellow crystal sugars, which are manufactured directly from cane juice by a special process of clarification and boiling ; that is, of course, the genuine Demerara or Trinidad crystal sugars, and not the yellow crystals made by some houses in this country by incorporating white crystals (sometimes beet) with a syrup containing a suitable organic dye. They consist approximately of 96 per cent. of crystal surrounded by a syrup containing reducing sugars, ash, and organic non-sugars, including the bodies imparting the very pleasant taste and aroma of the cane juice. The precise nature of these flavouring substances remains undetermined.

COMPARATIVE SWEETNESS OF CANE AND BEET SUGARS

The opinion appears to be quite widely held, and in fact is often definitely expressed, not only by the general public and by sugar salesmen, but also by physiologists who have considered the matter, that the various grades of sugar on the market do actually differ in sweetness, in spite of the fact that their sucrose content may be about the same. Even in Germany there are many who admit that "colonial sugars" (*i.e.*, cane products) are sweeter than the lowest grade granulated beet sugar sold there, or even than the char-refined beet product. It seems, therefore, of some interest to examine the question, and to state the known facts which may account for such an opinion.

Preliminarily, it may be pointed out that a correct judgment can hardly result from tasting the crystals themselves, since their size and hardness considerably influence the sweetening effect thus obtained. It is evident that a fine and soft-grained sugar will pass more quickly into solution in the mouth than a product consisting of hard and large crystals. Obviously, therefore, tasting experiments must be performed with solutions of the various samples, using preferably a saporimeter, such as that designed by Kremer (Nederl. Tijdschrift voor Geneeskunde, 1917, No. 3, 149-157), whilst also following a suitable method for diluting the sapid substance with water, and a definite procedure for eliciting the decision of the individual tasters, such as that described by Toulouse and Vaschide (Comptes rendus, 1900, 130, 803; 1904, 139, 898).

The reader may be reminded that on the surface of the tongue and soft palate are numerous papillæ, of which many bear at the base or on the top the so-called "taste buds," structures which are the terminations of the gustatory nerve fibres. These nerve endings are capable on excitation of giving rise to gustatory sensations, which are broadly classified as sweet, acid, bitter, and salt. Each of these sensations is believed by many physiologists to be registered by a specific set of nerves; in other words, the particular nerve endings producing the sensation of sweetness appear to be incapable of excitation by an acid, a bitter, or a saline substance.

An important fact here to bear in mind is that there appears to be reliable evidence for the statement that the intensity of a gustatory sensation (sweetness, for example) may be modified when another set of nerves in the vicinity (say, those producing an acid taste) is at the same time excited (Zeitsch. f. Psychologie u. Physiologie der Sinnesorgane, 1899, Bd. 21).

INFLUENCE OF TRACES OF ACID AND ALKALI ON SWEETNESS

Thus, it will be found that if two solutions be prepared, the first containing 15 and the second 12 per cent. of sucrose, and if to the latter a trace of acid be added, it is possible by gradually increasing this addition to arrive at a certain concentration of the mineral or vegetable acid at which most of the tasters would consider the weaker solution of sucrose to be the sweeter (Archives Néer. Physiol., 1917, 1, 625). A similar result has been obtained by adding quinine hydrochloride and other bitter substances (Du Bois Raymond's Archiv f. Physiologie, 1892). It has been established that if two solutions be made up both containing, say, 15 per cent. of sucrose, and if to one of them about 0·1 per cent. of sodium chloride be added, nine persons out of ten tasting the two liquids would declare the solution containing the small amount of salt to be appreciably the sweeter (Archives Néer. Physiol., 1917, 1, 625). It is, of course, well understood that if the amount of any one of these additions is increased beyond a certain point, the acid, the bitter, or the saline taste will become apparent, and the solution of sucrose will then certainly become less sweet. On the other hand, it has been proved that traces of alkali depress the sweetening effect of a solution of sugar, and a well-known German chemist once stated (Vereinszeitschrift, 1892, 42, 580): "According to my experience, the sweetness of sugar is greater when traces of acids, especially fruit acids, are present than in solutions which, as in the case of our beet sugars, contain a trace of alkali."

INFLUENCE OF ODORIFEROUS AND OTHER FOREIGN SUBSTANCES

Further, the sense of taste is certainly affected by odoriferous substances. In an authoritative textbook ("A Textbook of Physiology." By Sir Michael Foster, in Part IV. The Senses. Page 1513) the statement is made that if the nose be held, and the eyes shut, it is very difficult in eating to distinguish between an apple, an onion, and a potato, the three being recognised when their respective aromas are eliminated only by their texture in the mouth, and not by their "taste." W. H. Th. Harloff remarked (Intern. Sugar J., 1920, 105) that when palm sugar (which is exceedingly luscious) is dissolved in water and treated with a decolorising carbon for the absorption of its non-sugars, one obtains a liquid that is much less sweet than the original solution, although its content in sucrose and reducing sugars may be the same. A similar observation was made by F. I. Scard (ibid., 1904, 478) to the effect that the pure sucrose obtained by washing Demerara sugar to remove the adhering syrup, and recrystallising the white sugar left appeared almost tasteless in comparison with the original crystals.

These several points regarding the factors capable of influencing the sweetness of a sugar seem to be well established; and in fact are so well recognised that the proposal has been made to add traces of vegetable acids and flavouring substances to pure white sugar for the purpose of increasing its sweetness and palatability as a commercial article.

Summarising the conclusions to be drawn from the observations cited above, it may be said that there appears to be good evidence for the opinion that some grades of white sugars, namely, those containing traces of acid and flavouring substances, may be sweeter than others, when tasted in solution. Thus, by way of example, if one were to examine in the manner already indicated four different grades of sugars, viz., (1) the best refined; (2) a low grade cane direct consumption; (3) Demerara yellow crystals; and (4) an inferior beet direct consumption, there seems little doubt that in the opinion of the tasters the Demerara yellow crystals would be considered somewhat sweeter, weight for weight, than the refined article, in spite of there being a difference of about 4 per cent. in the sucrose content of the two sugars. Further, it seems certain that the direct-consumption cane sugar would be adjudged slightly sweeter than the refined, though less sweet than the Demerara product; whilst the least sweet of the four would probably be the inferior beet, especially if this were of the washed crystal type containing a small amount of alkali carbonates, such as was imported into this country from Germany and Austria previous to the war.

PRESERVING QUALITY OF CANE AND BEET SUGARS

The preserving quality of a sugar, whether derived from the cane or from the beet, depends upon several factors, two of the principal of which are: (1) its freedom from micro-organisms capable of inducing fermentation; and (2) its reaction, which should be neutral, or slightly acid. It should also be free from any flavouring or colouring matter which may adversely affect the taste or appearance of the preserve.

In regard to the first factor, namely, freedom from septic micro-organisms, it was formerly claimed that refined sugars only should be used for preserve-making on the ground that it was only by the use of animal charcoal that a sterile product could be obtained. However, direct-consumption sugars made from both cane and beet are in use at the present time in the jam, fruit-canning, and condensed-milk industries with results as satisfactory as those obtained with the refined grades.

It is now known that in the manufacture of direct-consumption sugar, whether by sulphitation in the cane-sugar house, or by carbonatation in the beet factory, a practically sterile juice results after allowing the precipitate of calcium sulphite or carbonate to subside or filtering off. (Intern. Sugar J., 1919, 465). Subsequently, both in refining and in manufacturing direct-consumption sugar, some re-infection occurs when the crystals are exposed to the air in the centrifugals, due no doubt to the large volume of air which is sucked against the mass during its very rapid revolution; but later if the sugar be treated with steam while still in the machines practically all the bacteria and moulds are destroyed (Intern. Sugar J., 1920, 591). The importance of the sterilisation of sugars in this way, and of their packing, storage, and transit under cleanly conditions, is now recognised by manufacturers of high-grade direct-consumption sugars.

Coming to the second factor mentioned above, namely the reaction of the sugar, it is of course well recognised that in jam and jelly manufacture the fruit juice must have a certain acidity, otherwise the pectin will not jell. Investigation of the reason why in preserve-making a syrup instead of a jelly may result has sometimes indicated, when a low-grade beet sugar has been employed, the presence of alkali carbonates in sufficient amount to lower the acidity of the fruit juice below the optimum for the setting of the pectin. However, this condition is hardly likely to be encountered at the present time, though it may well serve as some explanation of the origin of the popular prejudice which persists against the use of beet sugar for the purpose. Most of the white grades of cane and beet sugars now on our market are of high purity; and the British beet sugars have been shown to give entirely satisfactory results in the jam, condensed-fruit and other industries in which sugar may be used In jam and jelly manufacture it would seem that in the event of trouble the sugar used is usually the factor for suspicion; whereas the actual reason for the refusal of the fruit juice to jell is more likely to be connected with other causes, such, for example, as the low acidity of the fruit juice, an insufficient pectin content, the hydrolysis of the pectin by prolonged boiling, or the use of too high a proportion of syrup.

CANE SUGAR v. BEET SUGAR

The death-blow to the notion that for some peculiar reason or other sugar which is derived from the beet is unsuitable for use in the preparation of jam or jelly and fruit preserving was given by G. W. Shaw, of the Experiment Station of the University of California, in a series of comparative tests (Intern. Sugar J., 1919, 619). The cane sugar was a product originating from the Western Sugar Refinery, San Francisco, and had a sucrose content of 99·7; whereas the beet sugar was a white granulated product made directly from the root by the American Beet Sugar Co., of Oxnard, Cal., and polarised 99·8 per cent. A large number of fruit-preserving tests (about 2000) showed that the two sugars gave identical results, and that in both series the product was as clear as it was possible to be. Not the slightest difficulty was experienced in the preservation in either case.

EMULSIONS IN TECHNICAL PRACTICE

THE study of the physico-chemical basis of emulsions, and of the colloidal and surface-tension phenomena they exhibit, has advanced technical practice in the formation and breaking of emulsions to a considerable degree, and empirical experimentation has helped to solve many problems in this field by accumulating data for subsequent scientific investigation.

Processes for the formation of stable emulsions on the one hand, and the resolution of undesirable emulsions on the other, are of general interest to chemical technologists. Thus, every year in this country tens of thousands of tons of "soap stock" are produced in the refining of vegetable oils, and as much as 80 to 90 per cent. of the neutral-oil content can be recovered, instead of being sold at a relatively low figure in the "stock" for soap-making or in the "black grease" obtained on acidification.

The dehydration of tars involves the separation of emulsions, and it is well known that many water-gas tars cannot be dehydrated by settling, even at raised temperatures and after long periods of treatment. The slow process of settling raw linseed oil, to obtain oils free from water and mucilaginous matter for use in the paint and varnish industry, can be hastened considerably by applying the principles of emulsion breaking. A final instance, though not of direct interest to this country, is of world importance, viz., the separation of petroleum emulsions. Comparatively recently millions of gallons of mineral oil were wasted annually owing to the impracticability of removing the water from the oil emulsions found in many oilfields.

The value to the manufacturers of "solid" and colloidal lubricants and to the textile industry of scientific data regarding emulsion formation and stabilisation to the margarine industry cannot be overestimated.

EMULSIONS

To form a stable emulsion of two immiscible liquids, a third component is necessary, which may consist of an emulsoid. According as one or other component becomes the disperse phase (*e.g.*, in emulsions of oils and water) a hydrophilous or a hydrophobous colloid has to be found. Soap, gum arabic, starch, gelatin, etc. may serve as emulsoids, and a film is formed at the interface between the two components.

Finely-divided solids may also help to produce permanent emulsions. Thus, Pickering demonstrated that oil-water emulsions could be produced by means of finely-divided solids, provided that the solid was more easily wetted by the water than by the oil; in this case the water becomes the disperse phase and the oil particles of the continuous phase are coated with a stable film of finely-divided solid. Later it was shown that water-in-oil emulsions could be formed by means of carbon black and similar substances, more easily wetted by the oil than by the water. Thus, a stable emulsion of water in kerosene can be prepared by means of carbon black, the black separating at the oil-water interface. Emulsions produced by means of finely-divided solids resemble in most respects those formed with the aid of a soluble emulsifier—a hydrophilous or hydrophobous colloid.

The extensive subject of emulsion formation and stability cannot be discussed here, it must suffice to state that the above two methods of formation are of especial interest in considering such problems as those presented by oilfield emulsions, soapstock separation, tar-dehydration, etc. The breaking or resolution of emulsions involves consideration of the relation between stability and size of particles, of viscosity of the respective components, and relative specific gravity. In this place only the practical methods evolved for disturbing the equilibrium of the emulsion system will be considered.

SEPARATION OF EMULSIONS

Much of the work done on the separation of emulsions on a technical scale has been inspired by the wastage of valuable mineral oil in the oilfield emulsions (*cf.* J. Ind. Eng. Chem., Nov., 1921), but many of the developments are applicable to other types of emulsions, with little or no modification.

It may be of interest first to record methods as yet unused in practice, and depending upon the differential wetting of filtering media. The use of kieselguhr has been advocated, the underlying principle being that during filtration this substance should "cut" and destroy the protective film surrounding the water particles in an oilfield emulsion (water in oil) and so allow of rapid coalescence and subsidence of the water by gravity.

GRAVITY *

The first attempts to deal with oilfield emulsions were based upon subsidence, but the impossibility of treating many types even after very long periods of settling at ordinary temperature, led to settling in pools exposed to the heat of the sun. The reduction of viscosity consequent upon raised temperature allowed of separation to some extent and in certain cases, but was only feasible when low-boiling fractions of the crude oil commanded no market value. Continuous settling in closed tanks suitably heated, naturally followed upon the introduction of the internal-combusion engine. Heating of the oil cannot, in many cases, be effected by direct heat from steam-pipes or jackets, as the water particles near the steam-pipe volatilise and then condense in extremely finely-divided particles in the cooler parts of the oil emulsion, which becomes more stable. In such a case the emulsion should be floated upon water into which steam is blown. Convection currents are set up and the emulsion is heated without vaporising the water; in this manner coalescence and subsidence by gravity are hastened.

Such methods are, however, cumbersome in application, and are not in general use. Mention, however, should be made of the increased difference in specific gravity produced by adding an oil solvent, such as petroleum ether. The reduction of viscosity and specific gravity of the non-water part of the mixture allows more ready separation of the water component, but the method is seldom adopted in practice. The following suggestion may, however, be noted. The emulsification of certain oils of asphaltic base is said to be due to earthy matter coated with asphalt, a mixture which, being an oil-soluble colloid stabilises the water-in-oil emulsion. On adding a solvent the asphalt dissolves and leaves the finely-divided earthy matter, which is not an oil-soluble colloid, so that the emulsion becomes more easily resolvable. The effects of reduced viscosity and greater differences in density must, however, be of moment in the final separation of the components.

Addition of Reverse Emulsoid

If an emulsion is stabilised by a hydrophobous colloid, as in water-in-oil emulsions, the stability of the whole can be decreased by the regulated addition of a reverse colloid, a hydrophile, and breaking by settlement often results in relatively short time. Separation can often be caused by carefully adding a water-soluble soap and ensuring contact with the water globules in the emulsion. Such a hydrophilous colloid, however, will *stabilise* an oil-in-water emulsion, and it is therefore necessary to add a colloid which will easily make contact with the dispersed water in the water-in-oil emulsion. Such hydrophilous colloids are represented by a mixture of sodium oleate and oleic acid, sodium resinate and free resin, etc., the mixture being able to make contact with the dispersed water globules through the oil.

It is probably impossible to separate all types of oil-field emulsions by the use of one particular reverse colloid, and each emulsion should be regarded as a separate problem. Nevertheless, use of the compound known as "Tret-O-Lite" has met with considerable general success in recovering oil from emulsions that were formerly wasted. The compound consists of sodium oleate 83%, sodium resinate 5.5%, sodium silicate 5%, phenol 4%, paraffin 1.5% and water 1%. More recently the use of compounds containing sodium salts of sulphonated oils has been suggested.

Electrical Methods

It has been suggested that the addition of electrolytes to an oil-field emulsion will cause separation of the water particles, negatively charged; in particular, acids and ferric salts have been recommended, but they have not come into general use.

The coalescence and subsequent subsidence of the water globules has, however, been successfully accomplished by using a high-potential electrical field. The action, which was suggested by the successful methods of precipitating dust, is stated to depend upon the electrical charge borne by the water globules; the enveloping oil-film is ruptured, the water particles coalesce more readily, and separation by subsidence follows.

The apparatus that has found favour in many districts consists of a tank, 3 ft. in diameter and 8 ft. high, containing a centrally disposed revolving electrode. The electrode shaft carries a number of circular discs and is supported by an insulated bearing. The tank itself, being earthed, serves as the second electrode. The oil is fed continuously into the annular space between the tank and the central electrode, and a potential difference of about 10,000 volts is maintained between the tank and central shaft. The treatment of the oil-emulsion can be carried out at raised temperatures, say, 135° F., the maximum temperature advised being 180° F. To avoid loss of the valuable lower-boiling fractions, the treatment is carried out in closed systems and under pressure. After passing through the electrical field, the mixture is led to a trap settling-tank, where the oil and water are finally separated by subsidence.

The capacity of such an electrical system varies from 300–1000 barrels per 24 hours, and naturally the power consumption also varies. From 5–75 watt-hours may be required per barrel of oil treated, but the cost does not average above one cent per 20–50 barrels. The over-all cost, including steam, power, labour, repairs, interest, depreciation, and royalties ranges between 1 and 3 cents per barrel of oil recovered.

It is claimed that this system is universally applicable, and that it can be successfully used for such stubborn emulsions as "Tank bottoms." The system has been chiefly used in California.

The claim advanced by advocates of electrical treatment, that all emulsions can be economically treated in the above manner, is challenged in some quarters, but there is no doubt that similar methods are useful for breaking several different types of emulsions. The coagulation of finely-divided particles in suspension in oils by applying electrical force so that a rapid continuous settling process becomes possible, is a case in point.

CENTRIFUGAL SEPARATION

The increased rate at which emulsions can be separated by applying centrifugal force has been much advocated by the makers of the Sharples "Super-Centrifuge," which is capable of developing a speed of 18,000 revolutions per minute in large-scale apparatus. The emulsion can be treated at a raised temperature, as the loss of valuable light fractions is negligible on account of the speed at which separation is effected. The main factors of coalescence and subsidence are altered only in respect of time of operation, and the speed at which the oil and water are separated may be increased still further by the aid of reverse colloids.

Thus, the addition of starch in an oil-soluble state caused a certain oil emulsion to separate at the rate of 5 barrels per hour, and when 0·001 per cent. of oil-soluble sodium soap, starch, or glue was added to the emulsion several hours before centrifuging the rate of separation was 15 barrels per hour. Slightly larger amounts of hydrophilous emulsoid are required if centrifugal force is applied nearer to the time of addition.

On the ground that the hydrophobous emulsoid is present in all oil-field emulsions in approximately the same small amount, it is claimed that the above treatment, or a slight modification of it, is applicable to all forms of such emulsions. Much success has certainly been achieved by the use of the "Super-Centrifuge," but whether it is the alpha and omega of oil-field emulsion problems is still disputed.

The cost of treatment by centrifugal force has been placed at 7 cents per barrel, which compares unfavourably with the electrical method, provided emulsions are equally capable of treatment by the two methods. The Super-Centrifuge has, however, proved its great value in separating soap stock, an emulsion produced in large quantities in refining vegetable oils, and until recently sold without separation of its content of valuable neutral oil.

SOAP-STOCK SEPARATION

Of the methods of emulsion-breaking mentioned, the application of the Super-Centrifuge is the only one that has been worked successfully. As much as 80–95 per cent. of the neutral-oil content of soap stock has been recovered regularly in the form of an easily refined oil, which is much more valuable than as a component of original soap stock or of the "black grease" obtained from it.

The soap stock is treated in two distinct stages. In the first, the stability of the emulsion is decreased by diluting with 0·5–2·0 volumes of water, and heating to 100° C., 2 per cent. of sodium carbonate also being added. Other salts, or a weak acid such as boric acid, may be employed, but salting out of the soap and decomposition of either neutral oil or soap should be avoided. The diluted soap stock is then allowed to settle, and the lower layer of aqueous soap solution is withdrawn.

The second stage consists in the centrifugal treatment of the destabilised emulsion, whereby two products are obtained, the one consisting of neutral oil containing very small quantities of soap solution, and the other of soap solution with little oil. The neutral oil is treated with salt to separate the small quantity of soap, and is then ready for final refining to an edible product.

The value of the process can be judged by the fact that from 80–95 per cent. of the neutral oil can be recovered, say, from an oil-content totalling 25 per cent., and this oil is approximately three times more valuable than that present in soap stock.

The constructional details of the Super-Centrifuge need be indicated but briefly, full descriptions being available elsewhere. The machine consists of a small, high-speed elongated or tubular bowl capable of revolving at 18,000 revolutions per minute. The bowl, 4–5 in. in diameter, is supported and driven from above, and there is only one set of ball bearings. There is little wear and tear, and the machine runs very smoothly, except perhaps whilst attaining its full speed. An extension from the bowl, however, runs in a socket and guides the rotating bowl during this period. Afterwards the bowl is free to find its own axis.

CORRESPONDENCE

THE CHEMIST AND THE MANUFACTURER

Sir,—The contribution of Mr. A. A. Drummond to an old-time controversy suggests a treatment of the problem by the psychological method of Oliver W. Holmes.

The Manufacturer, M, represents three personalities, M', M'', M''': the Chemist similarly.

M'—C' are the actual men.

M''—C'' the ideals of M'—C', each of each.

M'''—C''' the respective reciprocal ideals.

Consequently, in any and every contact, the number of psychological equations to be satisfied is not less than 3×3, a complication which partly explains. "Plus ça change, plus c'est la même chose," and, freely translated, "maimed shows."
—I am, Sir, etc.,

C. F. CROSS.

Lincoln's Inn, London.
August 8.

Sir,—In your issue of August 15 a letter under this heading raises the interesting and important question of what the colleges are doing for industry.

One may presume that a large number of the chemical students in our colleges and universities are anxious in due course to obtain situations in British chemical factories. Apparently some of those responsible for their training consider it necessary to provide those embryo factory chemists with a complete supply of German chemicals for their laboratory work.

In spite of all the lessons of the war, in spite of the tremendous efforts which have been made to render our teaching institutions independent of German laboratory chemicals there are again, I regret to say, cases, which one could name, of prominent universities obtaining the bulk of their supplies from German sources. These universities are supported by grants of public money—the money of the British taxpayer. I know that these institutions will reply that they can buy these foreign chemicals so much more cheaply. Perhaps they can for the moment, but one wonders whether in the long run it is cheap to teach our young chemists the use of foreign chemicals, and thus help to stifle a section of that very chemical industry to which many of them are looking for future employment. With your correspondent I would say to the universities: "Broaden your outlook; teach patriotism toward your industry." Who but madmen would train students for occupations in any industry which they are helping to kill? Yet is not this the position of those who unnecessarily fill their laboratories with German chemicals for education and research purposes?

The colleges *can* do something for British chemical industry. They can, and should, endeavour to support it.—I am, Sir, etc.,

A Fine Chemical Manufacturer.

London, August 23.

NEWS AND NOTES

UNITED STATES

Autumn Meeting of the American Chemical Society

The meeting to be held in Pittsburgh from September 4 to 8 will probably be attended by 1500—2000 chemists. The chief address will be delivered by Dr. E. E. Slosson, author of "Creative Chemistry" and now editor of Science Service, Washington, on "The Constructive Chemist"; and the papers to be read include one by Mr. F. G. Breyer on a new form of zinc oxide consisting of smaller particles than any existing form, and which is claimed to double the life of the tread of an automobile tyre. Dr. T. Midgley, jr., and Mr. T. A. Boyd will demonstrate the detonation of various motor fuels and explain how "knocking" of the engine may be reduced.

Following the meeting (September 11—16), the Eighth National Exposition of Chemical Industries will be held in the Grand Central Palace, New York, where the exhibits will be confined to products of American firms. About 450 American manufacturers are expected to participate, and an interesting feature will be the provision of kinematograph pictures and lectures on subjects relating to various branches of the industry. Two special sections, on fuel economy and on containers, have been added to this year's exhibition.

Pulverised Coal and Explosion Risks

The precautions which should be taken to minimise the risk of explosions when pulverised coal is used in industrial plants have been investigated by the Bureau of Mines and form the subject of a paper by Mr. L. D. Tracy. It is most important to prevent any accumulation of dust exposed to the air in any part of the plant as this is always liable to form an explosive cloud on being disturbed; a mixture of 0·032 oz. of coal dust with one cb. ft. of air has been found sufficient to cause an explosion when brought in contact with a flame. It is often assumed that sufficient inert matter becomes associated with the dust near furnaces to render it non-explosive, but this is not always the case. The proportion of inert matter which must be present with the coal dust to render it harmless is correlated with the ratio of volatile matter to total combustible matter in the coal. A dust containing over 30 per cent. of ash and only 11 per cent. of volatile matter was found to form an explosive mixture.

In France and Germany vacuum cleaning plants have been installed in connexion with coal-crushing plants in order to facilitate the removal of dust from all parts of the buildings and machinery. Much may be done to prevent the accumulation of dust deposits by maintaining plant in an efficient state, and the risks resulting from any accidental escape of dust may be minimised by consideration of the general lay-out. The drier should be in an isolated position and storage-hoppers should be isolated from boilers or furnaces. Particular attention is directed to all electrical equipment and to the possibility of an electrical discharge from any rapidly moving machinery. Spontaneous combustion of the dried coal is a frequent source of serious trouble. It is questionable whether greater efficiency is attained by working the drier at a higher stack temperature than 150° F., but in any case coal at a higher temperature should not be kept in storage. When the system of circulating pulverised coal is used there is always a risk of fires travelling back from the furnaces. This may be minimised by maintaining the pressure at all points of the distribution system higher than that of the secondary air supplied to the furnaces. A suitable vent should be provided near the outlet of the fan so that in the event of an explosion within the distribution-main the fan will not be damaged.—(*Proc. Eng. Soc. of W. Pennsylvania, June,* 1921.)

Lime in 1920

Although the sales of lime in the United States in 1920 increased in quantity by 7·2 per cent. to 3,570,141 short tons and in value by 27·5 per cent. to $37,543,840, the demand was greater than the supply. This shortage was due entirely to lack of skilled labour and to transport deficiencies, as many of the plants did not operate at full capacity. In all 1,000,550 t. of "chemical lime" was sold, 316,293 t. being used in making refractories, 104,250 t. for alkalis, 90,533 for purifying water, 88,465 t. for calcium carbide, 48,361 t. for acids and 21,845 t. for soap, oils and fats. The chemical industry also consumed the following quantities of lime and of hydrated lime, respectively:—Paper 365,897 t., 7237 t.; glass 54,747 t., 3232 t.; sugar 14,145 t., 4111 t.; tanneries 61,162 t., 14,828 t.; metallurgy 344,921 t., 1521 t. Of the 853,116 t. of hydrated lime sold, 116,748 t. was used in chemical industry. Sales of marl amounted to 97,487 t., mostly for use as an agricultural dressing and partly as a filler for fertilisers, and 38,506 t. of oyster-shell lime was sold for use on the land. Imports (mainly from Canada) and exports were small, amounting to 22,638 t. and 5921 t., respectively (*cf.* **J., 1922,** 175 R).—(*U.S. Geol. Surv., Nov.* 3, 1921.)

Production and Consumption of Sugar in 1921

According to figures published by the U.S. Department of Agriculture, the production of sugar in the United States in 1921 was as follows:—Beet sugar 1,012,382 short tons; cane sugar 270,270 t.; maple sugar 2547 t.; or a total of 1,285,199 t., compared with 1,269,913 t. in the previous year. The actual consumption of sugar in 1921 is given as 5,274,225 t., or 28·4 per cent. of the world's production and an increase of 25·9 per cent. over the average for the 10-year period ending 1920. The *per capita* consumption in 1920 was 97·8 lb., the largest amount recorded. About 1,066,463 t. of sugar was supplied by non-contiguous territories of the United States (Hawaii 488,869 t., Porto Rico 409,022 t., Philippines 168,572 t.) and 3,336,521 t. from foreign countries. Exports amounted to 394,632 t., a small increase compared with the average of the previous ten years. (*U.S. Com. Rep., Mar.* 6, 1922; *Ind. Tr. J., May* 18, 1922.)

Sugar Industry in the Philippines

Owing to the prosperity of the sugar industry in the Philippine Islands during 1919 and 1920, the Philippine National Bank and other corporations have built sugar centrals that bring the total up to 32. These centrals are scattered through central Luzon, the Manila district, and Negros, the chief cane-producing areas, and have an annual productive capacity of 320,000 tons of 96° sugar. The planters believe that it will pay to build more centrals and to cease marketing muscovado sugar in quantity. In Cotabato, province of Lanao, the area of suitable land is greater than that now under cane in Cuba, and the island of Negros already produces 60 per cent. of the cane crop of the Philippines. The prospects of building up a very important sugar industry are excellent.—(*Ch. of Comm. J., Apr.* 14, 1922.)

CANADA

Mining

Free gold bearing ore has been found on the property of the Gold Nugget Mining Co. at Ess Lake, Northern Ontario.

It is stated that some valuable mica properties, near Ottawa, Quebec, have been purchased by the Westinghouse Electric Co. of America.

South African mining interests have made an offer for the Teck-Hughes and the Orr Gold Mines, in the Kirkland Lake district of Northern Ontario.

The Nichols Copper Co., New York, has obtained the contract for selling the copper output of the Granby Consolidated Mining Co., which averages about 3,000,000 lb. a month, and is shipped from Anyox, B.C., to Laurel Hill, near New York, for refining.

The new cyanide plant of the Pioneer mine in Lillovet district, B.C., is ready for operation. There is a possibility of the Consolidated Mining and Smelting Co., Ltd. taking over the smelter at Ladysmith, Vancouver Island. If so, it would treat the gold, copper, silver and lead ores available from coast mines and drawn from the Omineca, Skeena, Naas River, Portland Canal and other mining districts. These ores now go to the Tacoma (Wash.) smelter or to the Selby smelter at San Francisco.

The Consolidated Mining and Smelting Co. is installing a copper rod mill at Trail, B.C., at a cost of about $250,000. It is expected that this will lead to the development of copper wire drawing in Canada.

Considerable activity is being shown in staking mining claims in the district east of Matheson, Northern Ontario. The Blue Quartz property near Painkiller Lake, has been bagging some good ore from the 100 ft. level. The vein is about two ft. wide and assays show the gold content to be from $44 to $166 per ton.

Petroleum

The Canadian Western Natural Gas Co. is boring, with a rotary drill of 17¾ in. diameter at Barnwell, Alta., to a depth of 2,600 ft.

Another syndicate, known as the White River Oil Co. is putting down test holes for petroleum in the Hay River country. The Hay river flows from Hay Lake north-easterly into Great Slave Lake, and the boring will be done at a point 13 miles up the river.

An oil boom has begun at Medicine Hat, Alberta, a city which is the centre of one of the world's largest gas fields. Since the discovery of gas about ten years ago, the borers have been satisfied to stop operations at the second gas level of 1700 feet. It is now believed that beneath the city and district is an immense lake of petroleum and the fever to bore for oil has developed. The Medicine Hat Development Co. has struck a heavy flow of wet gas at 1700 ft. which is reported to yield 2—3 galls. of gasoline per 1000 ft. This well is about 40 miles from Medicine Hat and, whereas the local gas is odourless, that from the new well has a pronounced odour. Five drilling rigs are in operation boring for oil in this district. Oil has been found in paying quantity in the northern part of Montana, just across the international boundary, in the Sweet Grass district (60 to 70 miles south of Medicine Hat). Boring has been started in the same territory on the Canadian side of the line, and rigs are being put up to drill for oil. The Imperial Oil Co. has purchased the oil lease on a farm ten miles east of Coutts, which joins the boundary, and faces a large block of land leased by two companies on the Montana side.

Pulp and Paper Industry

The Bathurst Lumber and Pulp Co., Bathurst, B.C., proposes to build a paper mill for newsprint. The new mill will give employment to 500 men.

The Westminster Paper Co., a corporation newly organised by capitalists from Peshtigo, Wisconsin, is erecting a paper mill at New Westminster, B.C. The company will specialise in the manufacture of tisue paper for home consumption and export.

Hollingsworth, Whitney, Ltd., of Boston, Mass., has purchased the timber areas and properties of C. T. White and Sons, Ltd., New Brunswick, and Davison Lumber Co., Ltd., Nova Scotia.

The timber areas of the White Co. in New Brunswick aggregate nearly 50,000 acres, including 83 sq. miles of Crown lands under license. The price paid for the properties is stated to exceed $2,000,000. It is proposed to erect pulp mills in New Brunswick and Nova Scotia.

A survey of the forests of Canada shows that, during the past 55 years, one-half to two-thirds of the forest area of Canada, or approximately one million square miles, has been destroyed by forest fires, and some of this territory has been devastated by fire as many as six times within half a century.

SOUTH AFRICA

Proposed Iron Works at Bloemfontein

It is announced that the Carron Co., of Falkirk, has applied to the Bloemfontein Municipality for 10 acres of ground on the Industrial Development Sites, for the purpose of establishing an iron foundry. The company proposes to spend £20,000 on buildings, and to import twelve skilled men from Scotland. Local unskilled labour will be used, made up equally of Europeans and natives.—(*S. Afr. J. Ind., June*, 1922.)

AUSTRALIA

Water Power in North Queensland

We have received a communication from Mr. J. Hastings Reed, who states that within 12 miles of the Port of Cairns, North Queensland, there exists an almost unlimited supply of water with a fall of 900 feet. It is proposed to instal a hydro-electric station, and excellent sites with cheap power will be available for electrochemical and similar factories. Local minerals include copper, lead, silver, gold, zinc, antimony, tungsten, molybdenum, manganese, iron, etc. Coal, coke, pure carbonate of lime, alumina, pure white siliceous sand and phosphate rock are available in large quantities. The port is served by the line of steamers plying between Australia and New Zealand, Japan, China, India, and the Straits Settlements.

NEW ZEALAND

Manufacture of Pig Iron in New Zealand

It is announced that the new blast furnace at Onakaka was first tapped on April 27. The furnace was erected by the Onakaka Iron and Steel Co., Ltd., formed for developing part of the large deposits of iron ore at Golden Bay. A modern plant has been installed and the company owns supplies of coal, iron ore, and limestone in favourable situations, but production at capacity will not be initiated until the coking ovens and transport arrangements have been completed. The cost of raw material per ton of iron at the furnace, including royalty, labour and freight, is stated to be: iron ore 12s., limestone 3s., coke 40s.—55s. Labour does not cost more than 15s., and it is estimated that coal from the company's mine, when opened up, will not cost more than 15s. at the works. The output will probably be 24 to 30 tons of pig iron per 24 hours.—(*Bd. of Trade J., July* 13, 1922.)

BRITISH INDIA

Industrial Notes

Bengal.—Dr. R. Lal Datta, who was recently appointed Industrial Chemist, has begun to investigate problems relating to the manufacture of shellac, the comparative efficiency of salt-raising on the sea-coasts of Bengal, Orissa, Madras and Bombay, the chemical composition of matches, the deodorisation of fish oil for making soap, the preparation of chemically-pure lime for industrial use from the shell-lime deposits of Bengal, the economic possibility of sugar-making as a home industry in Bengal, and of yarn-dyeing as a home industry. Schemes submitted to the Government include one for developing the glass and allied industries of Bengal and another for manufacturing dynamite glycerin under Government patronage.

Bombay.—A sample ton of improved casein will probably be sent shortly to the United Kingdom to ascertain the increased price commanded by material of better quality. Dr. Meldrum is investigating the preparation of rennet casein, the type required by makers of galalith; all Indian casein is lactic and has, therefore, been rejected for galalith manufacture.

The Geological Survey has made suggestions for improving the working of the alkali deposits of Sind, and a chemist will probably be detached to carry out check analyses on the spot.

The research work in Bombay on the discoloration of local magnesium chloride has not given satisfactory results, but the inquiry on the same subject at the Indian Institute of Science, Bangalore, offers more promise. The royalty payable by the Pioneer Magnesia Co. to the Government has now been fixed.—(*J. Ind. Indust., May*, 1922.)

Oil and Tallow in the United Provinces

The Industrial Chemist reports that the price obtainable for refined tallow is insufficient to pay the cost of refining on modern lines, as the price paid by textile workers for tallow refined by crude, native methods leaves very little margin of profit. Dr. E. R. Watson, of the Technological Institute, is investigating the possibility of using Indian vegetable oils to a greater extent in manufacturing lubricating oils for internal-combustion engines.—(*J. Ind. Indust., May*, 1922.)

New Sulphuric-Acid Factory in Bombay

The Dharamsi Moraji Chemical Co. has built a sulphuric-acid plant with a capacity of 7500 tons per annum which is the largest plant of its kind in India. It is reported that superphosphate will also be manufactured in the factory, which is one of the first to be built in the Ambernath area (on the G.I.P. Railway) now being developed in Bombay.—(*Chem. and Met. Eng., July* 19, 1922.)

GENERAL

Liverpool Section

The Liverpool Section of the Society is taking part in the organisation of an Associated Scientific Soireé to be held in the Liverpool Public Museum on Saturday, November 4. Space will be reserved for exhibits from members of the participating societies, and it is suggested that members of the Society of Chemical Industry in the district who would care to show specimens of materials or apparatus likely to be of interest, should communicate as soon as possible with the local secretary.

Platinum and Allied Metals, 1913—1919

A concise account of the properties, uses, prices and production of platinum and allied metals is given in this publication of the Imperial Mineral Resources Bureau (pp. 84, price 2s.). The world's output of platinum up to the present is estimated at about 11 million oz. troy, of which Russia has contributed about 90 per cent., Colombia 7 per cent., and Borneo 2 per cent., the remainder being furnished by the United States, Australia, and Canada. Probably 99 per cent. of this output has been derived from placers, but increasing amounts are being recovered at electrolytic-copper and bullion refineries. During the war period the output of platinum metals from placers declined from 175,181 oz. in 1913 to 73,435 oz. in 1920, but the fall in the Russian output from 157,735 oz. to 35,000 oz. was partly offset by an increase in that of Colombia from 15,000 to 35,000 oz. (crude). The geological features in certain areas of South Africa (Rhodesia and Cape Province) and of Spain suggest that platinum may eventually be won in payable quantities in these countries. Prices of platinum fluctuated greatly during the war, rising from 185s. per oz. early in 1914 to 220s. in September, 1916, 400s. in March, 1918, and 770s. in January, 1920, but falling to 390s. per oz. at the end of 1921. Platinum came into greater use as a catalyst in the contact process of making sulphuric acid, about 500,000 oz. being employed for this purpose towards the end of the war; losses of only 0·25 g. of metal per ton of acid made were reported, so that very little renewal was required. Platinum-iridium and nickel-chromium alloys, tungsten and molybdenum are gradually replacing platinum for use in the electrical industry, and in 1919 and 1920 in the United States over half the platinum consumed was used in making jewellery.

Iron and Arsenic in 1921

The following advance statistics, compiled by the Imperial Mineral Resources Bureau, show the world's production, imports and exports of iron and arsenic during 1921:—

IRON

			1921 Long tons
United Kingdom	Production	Pig iron	2,611,400
	Imports	Iron ore, including manganiferous iron ore	1,887,574
		Pig iron, including ferro-alloys	681,955
	Exports	Iron ore, including manganiferous iron ore	1,472
		Pig iron, including ferro-alloys	135,998
Union of S. Africa	Production	Iron ore	2,157
	Imports	Pig and ingot	1,023
Canada	Production	Iron ore	38,337
		Pig iron and ferro-alloys	616,847
	Imports	Iron ore	590,329
	Exports	Iron ore	3,804
India	Imports	Iron ore	9
		Pig iron	14,129
	Exports	Pig iron	51,942
Australia	Production	Iron ore	689,275
		Pig iron	352,365
	Exports	Pig iron	2,765
Austria	Production	Iron ore	670,000
		Pig iron	220,000
Belgium	Production	Pig iron	862,305
France	Production	Iron ore	13,879,000
		Pig iron	3,362,038
	Imports	Iron ore	418,196
		Pig iron and ferro-alloys	37,266
	Exports	Iron ore	5,212,845
		Pig iron and ferro-alloys	648,960
Germany	Production	Pig iron and spiegeleisen	8,000,000
Italy	Production	Iron ore	275,480
Luxemburg	Production	Pig iron	955,000
Norway	Imports	Pig iron and ferro-silicon	5,889
	Exports	Iron ore	188
		Pig iron and ferro-chrome	1,083
Soviet Russia	Production	Pig iron	967,741
Spain	Imports	Pig iron	24,135
	Exports	Iron ore	1,795,428
		Pig iron	4
Sweden	Production	Pig iron	3,036,000
Switzerland	Imports	Pig iron	24,282
Algeria	Exports	Iron ore	673,956
Tunis	Exports	Iron ore	200,733
United States	Production	Iron ore	29,547,000
		Pig iron	16,688,126
	Imports	Iron ore	315,768
		Pig iron and ferro-alloys	44,516
	Exports	Iron ore	440,106
		Pig iron and ferro-alloys	28,305

ARSENIC

			1921 Long tons
Southern Rhodesia	Production		322
Canada	Production	White arsenic and arsenic in ore	1,331
Queensland			220
France	Imports	Metal	5
United States	Production		5,116
	Imports	Arsenic and sulphide of arsenic	2,985

The Uses of Cotton Linters

An account of the characters, production and uses of linters is given in *Departmental Circular* 175 (1921) of the U.S. Department of Agriculture. Linters, which consist of the fuzz of the cotton seed together with any cotton fibre that has escaped removing during ginning, are used for stuffing mattresses and cushions, making absorbent cotton, felt, low-grade yarns for wicks, rope, felt, and, as cellulose, for making artificial silk, paper and explosives. During the war linters were greatly in demand for explosives manufacture, and by the introduction of new systems of delinting the yield was increased from 25 to 75 lb. to 140 to 200 lb. per ton of seed. By the "suction" system the fibre is blown from all the different delinting machines, mixed and united into one uniform grade. Although this system has since been abandoned as it does not give a product in the form of a felt, being therefore only of use in explosives manufacture, its value in saving labour and giving a cleaner and more uniform product has been appreciated and a method has now been devised by which the linters are converted into a felt. From 556,000 bales, or 3·5 per cent. of the cotton crop in 1911–12, the output of linters in the United States increased to 1,331,000 bales (10·9 per cent.) in 1917–18, but fell to 7·7 per cent. of the crop in 1918–19 and 5·4 per cent. in 1919–20. At present production exceeds demand, but it is hoped that the paper industry will use large quantities of it, and that other commercial applications will be found.—(*Imp. Inst. Bull.* XIX, 4, 1921.)

Determination of Hydrosulphite

Messrs. Brotherton and Co., Ltd., of Leeds, have published a pamphlet relating to the methods of determining sodium hydrosulphite in use in their laboratories. The preparation of pure indigo-carmine solution and of the hydrosulphite solution for analysis are described. A special apparatus is sketched, its use explained, and the precautions necessary to avoid oxidation of the indigo carmine reduced during the determination are detailed. In the silver method of estimating hydrosulphites a silver solution is prepared by dissolving one gram of silver nitrate in 10 c.c. of distilled water and adding 15 c.c. of a 20 per cent. solution of ammonium hydroxide. This solution is poured on to about 0·4 gram of solid hydrosulphite and the whole is well stirred. After about 5 minutes the grey precipitate of silver is filtered off, washed thoroughly with dilute ammonium-nitrate solution until free from silver nitrate, dried, ignited, and weighed; 216 parts of silver are equivalent to 174 parts of pure anhydrous sodium hydrosulphite.

A New German Periodical

Under the title "Wissenschaft und Industrie," Plauson's Forschungs Institut, of Hamburg, is issuing a new monthly publication under the editorship of Dr. H. Schmidt devoted to scientific and industrial research. The first number, published on July 15, contains articles by Plauson on the colour shown by colloid dispersions under the ultramicroscope, by Dr. H. Schmidt on corpuscular phosphorescence, and by Dr. J. Schmitt on a new organic reagent.—(*Chem.-Z., July* 6, 1922.)

"Germanit"

In *Metall und Erz* (1922, 13, 324) Prof. Pufahl, of the Berlin Technical *Hochschule*, describes the results of his investigation of a copper-sulphide mineral occurring in considerable quantities at Tsumeb in South-West Africa and containing nearly as much germanium as the mineral argyrodite (Saxony) in which C. Winkler discovered that element. The new mineral is always found associated with zinciferous arsenical pyrites and has a dark reddish-green colour and a weak lustre. Analyses of two hand-picked specimens gave (per cent.): Cu 45·4, Fe 7·22, Ge 6·20, Zn 2·61, Pb 0·69, S 31·34, As 5·03, and SiO_2 0·75. The name "Germanit" has been given to the mineral.

The Fertiliser Situation in Germany

In a recent debate in the Reichstag, the Minister of Food and Agriculture said that during the past fertiliser year synthetic nitrogenous fertilisers were utilised in greater quantity than in the years before the war. Supplies of phosphoric acid, although not so abundant as those of nitrogen, were twice as large as in the previous year, and would probably improve still further in the current season. Potash, as in former years, would be available in sufficient amount. Although prices of fertilisers had been kept stable during the past year and the prices of superphosphate, "Rhenania" phosphate, and bone meal had been temporarily reduced in June, 1921, the heavy costs of production and diminished output made great increases necessary at the end of the year. As doubt had been cast on the accuracy of the basis upon which the prices had been calculated, the question of evaluation was to be investigated. The value of fertilisers in maintaining yields was being increasingly recognised, especially among the peasantry, owing to propaganda work and demonstrations.—(*Chem. Ind., May* 29, 1922.)

The Industrial Value of Ostwald's Colour Rule

Ostwald has proposed to replace the prevailing custom of describing colours merely from their appearance by a method which enables any colour to be expressed as a numerical quantity. In this method all the colours are arranged in a circle, starting from yellow and passing through orange, red, violet, ultramarine, blue-green, sea-green, yellow-green, to yellow again. If the circle is divided into 100 parts the "colour tone" of yellow is 00, of red 25, of blue 50, of green 75. Conceptions of lightness and purity of colour are expressed by means of letters. If one colour is merely lighter than a second the first contains more white; if pure in shade it contains more black. Thus 53 *l c* represents a colour of "tone" 53 with whiteness *l* and blackness *c*. Ostwald has also propounded rules for combining two colours to form a third and for making up colour schemes involving a number of colours. The German colour industry does not seem to have accepted the system on account of practical difficulties which arise probably because the personal factor is not entirely eliminated.

Treatment of Acute Benzene-Poisoning with Lecithin Emulsion

A workman, 37 years of age, who had inadvertently drunk 80 g. of benzene came under treatment 1½ hrs. after, and when the stomach had been washed out, 5 c.c. of 10 per cent. emulsion of lecithin was injected. After an hour the chief symptoms—coma, depressed pulse, cyanosis, etc.—had disappeared, and after 36 hours the only sign of the poisoning was a slight albuminuria, which disappeared after a few days. It is uncertain whether the lecithin combined with the benzene in the blood stream and thus prevented it from accumulating in the cells, or whether it removed the poison already deposited in the cells. No untoward consequences resulted from intravenous injection and the fear of a fat embolism proved ungrounded. Lecithin emulsion has also proved useful in a case of acute oxalic-acid poisoning.

The Glass Industry in Belgium

In 1921 the Belgian glass industry failed to maintain the level of exportation that had been reached in 1920, and the weight of glass exported was 39 per cent. less than in 1920 and 46 per cent. below that of 1913. Despite this decrease, Belgium regained, and even improved, its former position in foreign markets for plate and window glass and table ware; thus the export of window glass to the United States was over twice as much as in 1913. Imports in 1921 were 61 per cent. greater than in 1920 and 28 per cent. less than in 1913. France supplied all the rough plate glass, but Germany, though still leading, monopolised some lines and shared others with France, Great Britain, Holland and Austria. Details of the imports and exports in 1921 are appended:—

	1921	
	Imports	Exports
	Metric tons	
Plate glass	44·4	24,629·4
Window glass	816·3	111,008·3
Bottles	14,924·7	2,374·7
Demijohns, wicker-covered	52·4	32·6
Ware of green glass (not bottles)	168·7	158·8
Table-ware	170·4	18,087·7
Other glassware	2,503·6	1,244·1
Total	18,680·6	157,335·5
Value, francs	23,222,784	271,665,662

Conditions in the Belgian glass industry were unfavourable during the first quarter of 1922; the demand was poor, prices were reduced by plate-glass factories in the United States, Germany and Czechoslovakia were competing strongly in flint and table glass, and prices of certain staple raw materials were rising. In the window-glass industry only 17 furnaces were operating, the plate-glass factories were working at about 50 per cent. of capacity and only five furnaces were producing special glass. Plants producing superior types of bottles were fully occupied, but those producing common bottles lost trade to Germany. In view of the increasing use of Fourcault machines—over 150 are being installed in various foreign countries—and of Libby-Owens plants, the future of the hand-blowing plants in Belgium is not promising. Current prices of raw materials (in francs per 100 kg.) for the glass industry are as follows:—Sodium sulphate 27; sodium bicarbonate 32·5; calcium carbonate, ground, 29; nitre, refined, 150; borax, crystallised, 157; fluorspar, ground, 25; felspar, ground, 21; cryolite 250; alumina, calcined, 280; manganese (87 per cent.), ground, 120 fr.—(*U.S. Com. Rep., Apr.* 17, *May* 8, 1922.)

Sugar Crop of Mauritius

According to the final estimate issued by the Mauritius Department of Agriculture, the sugar crop for 1921-22 is placed at 206,000 tons, or 20 per cent. below the normal yield, and the smallest crop since 1904, when it was 190,000 t. The sugar content of the 1921-22 crop was only 10·2 per cent., the lowest recorded during the past 10 years. This decline is due to the severe drought during the summer of 1921.—(*U.S. Com. Rep., July* 3, 1922.)

Chemistry in the Sudan

The work undertaken in the Wellcome Tropical Research Laboratories is very varied, ranging from the briquetting of charcoal (*cf.* J., 1921, 190 T) to wood preservation, sources of tannin, and cassava as a source of alcohol. Various samples of wood tar were examined in 1921, tamarisk wood yielding 8·9 per cent. of tar, which on distillation gave about 40 per cent. of tar oils and 60 per cent. of pitch—both products that could be utilised locally. The effect of the oils on wood as a protection against attack by white ants was tested and found to be inferior to that of coal-tar creosote; the method and material used, however, constituted a much more severe test than would be met in practice. Of the local sources of tannin, "dirimi" bark (*Burkea Africana*) has been examined, and the analysis gave, per cent.:—Moisture 6·5; ash 3·6; soluble solids 27·0; tannin 17·0. On account of the high price of petrol in South Sudan, bitter cassava (*Manihot utilissima*), a food crop grown in the Mongolia Province, was investigated as a source of alcohol. The material contained 72 per cent. of moisture and as the percentage composition of the dried material was:—Crude fibre 4·6; protein 5·5; ether extract 1·0; ash 3·5; carbohydrates 85·4, the material could probably be used as a source of alcohol.

Alcohol as Motor Fuel in Brazil

The National Brazilian Agricultural Society has recently completed tests relating to the value for motor fuel of a mixture of alcohol (95°) 65 parts, ether 25 parts, kerosene 9·5 parts, and pyridine 0·5 part. With this mixture, consumption per kilometric ton was 98.5 c.c., compared with 126 c.c. for gasoline, and the engine started easily and ran smoothly. With a mixture containing alcohol (95°) 83 parts, ether 10, kerosene 5, and pyridine 2 parts, difficulty was experienced in starting, the fuel consumption was 129 c.c. per kilometric ton, and the engine ran well only at the end of the test, which was carried out over a distance of 45·1 kilometres. Alcohol made from sugar-cane residues is sold at the Campos sugar factories in Brazil for about 275 reis per litre (about 9d. per gall. at current exchange), whereas gasoline costs 750 reis per litre in Rio de Janeiro (1000 reis = 2s. 3d. at par, now 7·4d.; litre = 0·22 gall.). The local factories could almost supply the needs of the Federal District and the State of Rio de Janerio, their productive capacity being 5·5—6·0 million gallons of alcohol. At present, however, the output does not exceed 1·75—2·2 mill. galls., and much of it is wasted through lack of transport facilities. If alcohol motor-fuel is to be used on a large scale, the cost of production must be reduced by organising storage and supply facilities, and the composition of the alcohol mixture must be standardised so as to produce the same power as gasoline.—(*U.S. Com. Rep., May* 15, 1922.)

PERSONALIA

Sir Robert Hadfield, Bart., has presented to the Metallografiska Institutet of Stockholm a scholarship of £150 per annum, tenable for two years, "as an expression of the debt of gratitude which the world owes to Swedish science.

Dr. J. Meisenheimer, professor and director of the Chemical Institute in the University of Greifswald, has been appointed to the chair of chemistry in the University of Tübingen, vacant by the death of Prof. W. Wislicenus, who had occupied it since 1903.

Engineer Vice-Admiral Sir George Goodwin, late Engineer-in-Chief of the Fleet, and Dr. J. C. Irvine, Vice-Chancellor and Principal of St. Andrew's University, have been appointed members of the Advisory Council to the Committee of the Privy Council for Scientific and Industrial Research.

In the examination for the Fellowship of the Institute of Chemistry, held in July, Mr. P. D. Oakley passed in Metallurgy, and Messrs. R. E. Essery and J. R. Walmsley in the Chemistry and Microscopy of Food and Drugs, and Water. Twenty-eight out of 45 candidates were successful in passing the examination in General Chemistry for the Associateship, and 6 out of 9 candidates passed the examination under the regulations in force prior to March, 1920.

In the United States, Dr. J. A. Ambler has been appointed chemist in charge of the colour laboratory of the Bureau of Chemistry, in succession to Dr. H. D. Gibbs; Mr. C. E. Betz has been appointed chief chemist of the Pittsburgh Testing Laboratory; and Prof. C. S. Bisson has left the S. Dakota School of Mines to take charge of the Department of Chemistry in the Northern Branch of the University of California; Dr. G. L. Wendt, professor of chemistry in the University of Chicago, has been elected president of the Standard Oil Co. of Indiana.

Ramsay Memorial Fellowships, of the value of £300 each, have been awarded to Dr. R. W. Lunt, to continue his work at University College, London, on chemical effects of electromagnetic waves over the frequency range 10^{-5}—10^{-8} cycles; to Mr. J. A. Mair, of Glasgow University, to pursue his research on the chemistry of the terpenes; and to Mr. W. Davies to continue his investigation on the preparation of synthetic reagents from the toluic acids. Fellowships have also been granted to Dr. J. O. Lublin and Mr. A. W. Bernton (Sweden); Mr. Dag Nickelsen and Miss M. Prytz (Norway); and Dr. C. S. Piggott, of Baltimore.

The British Research Association for the Woollen and Worsted Industries has awarded research fellowships to Mr. G. W. Chester, of Liverpool, to investigate wool fats at the University of Manchester; to Mr. J. L. Raynes, of Nottingham, to study the bleaching of wool at the University College, Nottingham; and to Mr. G. Barker, of Baildon, to conduct research at the University of Leeds on the effect of water on the strength, elasticity, lustre, dyeing properties, etc. of wool. Advanced scholarships have been awarded to Mr. A. Banks, Keighley, and Mr. W. E. Elliot, Hawick, tenable, respectively, at the Bradford Technical College and the Central Technical College, Galashiels.

OFFICIAL TRADE INTELLIGENCE

(From the Board of Trade Journal for August 10 *and* 17).

OPENINGS FOR BRITISH TRADE

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence), 35, Old Queen Street, London, S.W. 1, from firms, agents, or individuals who desire to represent U.K. manufacturers or exporters of the goods specified. British firms may obtain the names and addresses of the persons or firms referred to by applying to the Department and quoting the specific reference number.

Locality of Firm or Agent	Materials	Reference Number
Argentina	Earthenware	154
"	Disinfectants, sheep and cattle dips	156
"	Sulphuric acid, aluminium sulphate (tender for)	4390/F.L./C.C.
Australia	Perfumes in bulk	133
"	Perfumery, soap	161
"	Commercial sodium acetate (tender for)	9320/E.D./C.P.
Belgium	Paper	174
British West Indies	Steel sheets, tubes (tender for)	135
Chile	Enamelware, glassware, crockery, lubricating oils, tinplate, galvanised sheets	201
Egypt	Animal oil for denaturing ethyl alcohol (tender for)	8759/F.E.
Finland	Perfumery, polishes	177
Hungary	Copper sulphate	180
Luxembourg	Ferromanganese for iron and steel works	181
Mexico	Tin	160
"	Tinplate, black and galvanised sheets	202
Netherlands	Chile saltpetre (tender for)	15665/F.W./C.P.
Netherlands East Indies	Paint	153
New Zealand	Glassware	167
Norway	Tinplate, galvanised plates	142
"	Chemicals, iron and steel	F.R./5840
South Africa	Glass bottles, enamelware	169
Spain	Steel, tinplate, varnish, gums, shellac, fish oils	144
Switzerland	Raw materials for the chemical industry, intermediates for making coal-tar dyes	151
"	Pharmaceutical chemicals	152
United States	Fire-bricks, cement	198

TARIFF CUSTOMS EXCISE

Belgium.—The "coefficient of increase" applied to the duties on crystallised and granulated sugar has been reduced from 2 to 1·5.

Cyprus.—Imported fertilisers must be accompanied by a declaration of origin and the percentage contents of nitrogen, phosphoric acid, and potash in a soluble form.

Federated Malay States.—The import duties on matches have been revised.

Gold Coast.—The system of valuing goods for customs duty has been amended.

Ireland.—The Provisional Government has prohibited the importation, save under licence, of liquid fuels, lubricating oil, sheet metal, and iron plates.

Kelantan.—The import duty on lime has been raised from 3 per cent. to 10 per cent. *ad valorem.*

Memel Territory.—A list of customs duties applied to spirits, ether, salt, mineral and resin oils, and hides is given in the issue for August 10.

Newfoundland.—It is proposed to exempt imports of kerosene oil, gasoline, bark, bark extract, cutch, potassium dichromate, and logwood from the sales tax of 5 per cent. *ad valorem.*

New Zealand.—Celluloid and other capsules are admitted duty-free under the British preferential tariff. The conditions under which dumping duties will be levied are set out in the issue for August 17.

Nigeria.—The export duties on hides and skins have been reduced.

Portugal.—Special surtaxes have been imposed on exports of cork, oilseeds, palm oil, and vinegar.

Portuguese East Africa.—The additional duties levied on imports of sugar, spirits, alcohol, edible oils, benzol, gasoline, dynamite, gunpowder, mirrors, lubricating oil, soap, candles, salt, vinegar have been modified.

Southern Rhodesia.—Recent amendments of the customs tariff affect corks, kinematograph films, medicinal preparations, essences, syrups and tinctures, and starch.

REPORTS

THIRD REPORT OF THE DEPARTMENTAL (HOME OFFICE) COMMITTEE ON LIGHTING IN FACTORIES AND WORKSHOPS. *Pp.* 38. *London: H.M. Stationery Office,* 1922. *Cmd.* 1686. *Price* 9*d.*

Commencing with a brief review of the recommendations contained in two previous reports (*cf.* J., 1921, 318 R), the present report is devoted principally to the classification of industrial processes according to the illumination they need, and to the effects of mixed natural and artificial lighting. For the present it is recommended that definite legal minima of illumination shall not be imposed for processes carried on in factories and workshops, but that a specification of minima as "recommended practice" for different groups of processes shall be issued. Schedules A and B, contained in Appendix 1 of the present report, covering "fine work," for which the recommended minimum illumination is 3 foot-candles, and "very fine work" for which a minimum of 5 foot-candles is recommended, are suggested as the basis of such specification. Only those industries have been scheduled in which at least one process was judged to be "fine work" or "very fine work." Thus the iron and steel industry is entirely excluded and very few, if any, distinctly chemical processes are scheduled. Although no definite recommendations are made respecting processes needing only moderate illumination, it is pointed out that if the recommendations of the first report are adopted, the illumination at floor level in workrooms cannot fall below 0·25 foot-candle.

No conclusive results indicating special effects of mixed lighting (partly artificial light and partly daylight) were obtained, and at present no definite recommendations can be made on this matter.

The customary use of a naked source of light appears to be unnecessary for the examination of glass sheets during the bevelling process, and it is suggested that glass-bevelling shops should comply with the recommendation, contained in the second report, for avoiding glare.

Owing to the need for economy, the inquiries of the committee are concluded for the present. It is pointed out, however, that hardship to employers and administrative difficulties in the imposition of definite legal minima of illumination in workshops and factories would be largely avoided if a sufficient number of observations were collected indicating the best existing practice in the various processes, and if the conditions of illumination desirable on physiological and psychological grounds were investigated. The principal industries scheduled in Appendix 1 are invited to co-operate in this scheme by arranging for the collection of actual data, if possible through research associations.

Report on Peat by the Commission of Inquiry into the Resources and Industries of Ireland. *Pp.* 110. *Published by the Commission,* 87, *Grafton Street, Dublin.* 1921. *Price* 2*s.* 6*d.*

Many attempts have been made to develop the Irish peat deposits on a large scale and a special report was made to the Fuel Research Board only last year (*cf.* J., 1921, 229 R). All the attempts to manufacture pressed peat-briquettes have failed, and research has been directed towards the more efficient winning of peat by the use of machines of the Wielandt, Baumann, or other type, and the generation of cheap power in installations comprising either a water-tube boiler and turbo-generators or large gas-producers and gas-engines (*cf.* J., 1920, 213 R).

The commission of inquiry considers that experiments should be made to determine how far the percentage of water in peat can be reduced by "bottom drainage," and would compel turbary owners to co-operate in drainage operations. A recommendation is made that one or more of the automatic machines which have proved so successful in dredging, forming and spreading peat should be acquired by the Irish State and tested carefully on the Irish bogs. Air-drying of peat, depending, as it does, on the climate, makes the peat-winning industry discontinuous, and well-considered experiments should be initiated from time to time with a view to devising some successful method of drying peat by artificial means, even though at present it would seem to be quite uneconomical to do so. The manufacture of peat charcoal has proved commercially successful, whereas carbonisation for the production of illuminating gas has been a failure. Another outlet for peat would be its use in pulverised form, either alone or mixed with powdered coal, although this would have to be confined to rotary kilns or locomotives, and would not apply to large power stations. The most promising method of utilisation seems to lie in gasifying the peat in producers, and using the gas in stations not exceeding a few hundred horse-power in capacity. For large stations, the use of turbo-alternators is advocated, although when the peat contains a high percentage of nitrogen, it might be advisable to gasify it in by-product recovery plants and to use the resultant gas for boiler-firing, the steam being then used in turbo-alternators as before. The Commission is of the opinion that four stations, each designed to carry about 20,000 kw. constant load, would more than suffice for Ireland's requirements of combined nitrogen for the manufacture of nitrogenous fertilisers and explosives. The establishment is advocated of at least one station of 20,000 kw.-capacity by the Irish State in a suitable locality, part of the electrical power developed to be utilised at the bog for manufacturing calcium cyanamide and the remainder transmitted to centres of industry.

Moss-litter manufacture is commercially sound, but the Commission states that little hope can be entertained for any scheme for producing alcohol from peat. The cellulose constituents, on hydrolysis, yield unfermentable sugars, *e.g.*, arabinose, in addition to fermentable sugars such as glucose. It rarely happens that the percentage of dry turf which can be converted into alcohol exceeds 12 per cent. One ton of air-dried moss yields about 10 gallons of absolute alcohol, but the main expense is incurred in distilling the very weak wash, which contains only about 0·6 per cent. of alcohol.

The Bogs Commissioners of 1809—1814 recommended the utilisation of cutaway and virgin bog, a recommendation with which the present Commission agrees, whereas an agricultural sub-committee appointed by the Department of Agriculture and Technical Instruction for Ireland reported that the reclamation of virgin bog would not be remunerative even under the most favourable conditions, although the reclamation of cutaway bog might possibly be remunerative under certain conditions (*cf.* J., 1921, 229 R). It is recommended that, in order to avoid speculation, the State should acquire all the larger bog lands of the country at bog value, and that a few very large bogs should be reserved by the State primarily for meeting national needs, and secondarily for carrying out national experiments on the utilisation of peat.

Report on the Trade, Industry and Finance of Syria, Dated April, 1922. *By* H. E. Satow, *H.M. Consul-General, Beyrout. Department of Overseas Trade. Pp.* 25. *London: H.M. Stationery Office,* 1922. *Price* 9*d.*

Syria possesses no industries, coal or petroleum, and agriculture is undeveloped and primitive Apricots, pistachio nuts, and wool are exported, but shipments of olive oil are declining owing to poor quality, and silk cocoons are produced for export to France and Italy. There is a certain amount of water power, but except at Damascus none is harnessed. The minerals include gold, copper, iron ore, manganese ore, chromite, gypsum, lignite (none of any value), and asphalt. Alluvial gold occurs in an extensive deposit near Antioch and panning tests are said to have yielded about 1·5 dwt. of gold per cb. yd. Large nodules of copper are found between Alexandretto and Aleppo, iron ore occurs to the north of the former town and manganese ore in Northern Syria, but neither of the two last-named minerals are suitable for industrial use. Chromite occurs abundantly, especially between Suedia and Alexandretta, and small amounts have been extracted. Gypsum is said to exist in quantity at Suedia and asphalt is found in many localities, especially at El Becheri on the Euphrates.

Until the mandate for Syria is confirmed and the political situation in the Near East becomes clearer, the country's commercial future cannot be foreseen, and trade statistics are of value only in showing what goods are required. Imports through Beyrout in 1921 were valued at £9,889,458 (£2,629,161 from Great Britain and £1,895,844 from France) and included iron and steel bars, copper bars, cement, tiles, window glass, matches, dyes, paint, chemicals and soap. Exports were valued at £553,843, of which nearly one-half was directed to France.

COMPANY NEWS

The British Cyanides Co., Ltd.

The directors report states that the company's Tat Bank Factory was closed down throughout the whole of the year ended April 30, 1922, and that owing to foreign competition in potassium compounds it has not been reopened. The Pope's Lane Factory was reopened in August, 1921, and is now operating on a profitable basis. New processes have been worked out on a small scale for the manufacture of refined potassium compounds; one such compound is now being made by electrolysis on a profitable scale.

The experiments on the barium process for the fixation of atmospheric nitrogen have been energetically pursued and, although seriously hindered by the crises in the coal and engineering trades, have given definite results of a satisfactory nature. The merits of the new type of furnace designed by Sir Arthur Duckham have been proved and the directors believe that this great problem will be solved during the current financial year.

Severe competition in foreign potash having made it necessary to close down the works of the British Potash Company, Ltd. during the year under review, active negotiations have been entered into and are now in progress which, if successful, will enable the company to recommence operations on a satisfactory basis, but these negotiations are being conducted under considerable difficulties owing to the unsettled state of Europe.

The company has embarked upon the merchanting of foreign chemicals, and the profits earned during the year covered the initial heavy expenditure. The total net profit for the year was £2383, and after meeting the dividend on the preference shares there remains a balance of £492 to be carried forward.

Minerals Separation, Ltd.

At the 17th ordinary general meeting, held in London on July 29, Mr. F. L. Gibbs, chairman, described the success of the company's new processes for treating coal. The company had now a perfect system of cleaning fine coal; a system that would solve the problem of reducing the moisture-content of fine coal; and a new system of manufacturing briquettes which was less expensive and produced a much purer fuel than the present method. The trials of the briquetting system, carried out in conjunction with the Powell Duffryn Steam Coal Co., had been very satisfactory. Ground coal mixed with 50 per cent. of water was briquetted in a press, all the water, save about 4—5 per cent., was expressed as a clear jet, and the resulting briquettes became so hard in a few hours that they could be thrown about without breaking. The amount of binder required was only about one-third of that usually employed, and the briquettes made from coals belonging to the Powell Duffryn company could be obtained with only about per cent. of ash and 3 per cent. of moisture. It was unnecessary to dry the coal before briquetting and no pugmills were required. A plant with a daily capacity of at least 2000 tons of the new patent fuel ("Minseps") was to be erected on a site already acquired in Wales. The fuel had been tested on a Welsh railway passing up steep gradients and had given great satisfaction.

TRADE NOTES

BRITISH

Leeward Islands in 1920–21

Antigua suffered from severe and prolonged drought during 1920–21, and consequently the sugar crop was so reduced that only the abnormal prices ruling for sugar saved the industry from serious loss. Exports from Antigua included:—Sugar, molasses and syrups £314,562; cotton £16,362; hides and skins £1782; lime juice £1079; and green limes £246. High prices were again obtained for the sugar (12,483 tons) and cotton (251 t.) produced in St. Kitts and Nevis, but the fall in prices of all tropical products seriously affected the planters in Dominica and the export of lime products declined in value by £10,991 to £185,410; these products included lime juice, concentrated, 154,040 gallons, raw, 273,082 galls.; citrate of lime 304 t.; essential oil of limes 22·6 t.; and otto of limes 9 t. The factory established in St. Dominica by L. Rose and Co. for making citric-acid crystals should prove successful, as over 84 per cent. of the export of lime products in 1919 and 1920 consisted of concentrated juice and calcium citrate. Coconut-growing offers great possibilities in Dominica, but has received little attention; the export of coconuts increased by 214,553 to 706,979, which constitutes a record. Cotton is the chief product of Montserrat and the export was 248 t.; other exports were:—Lime juice 96,851 galls.; concentrated lime juice, citrate of lime, fresh limes £2734; muscovado sugar 116 t.; and papaine 821 lb. Good progress was made in extending the area under cultivation in the Virgin Islands; the cultivation of coconuts is spreading, but cotton is still the chief crop.—(*Col. Rep.-Ann.*, *No.* 1074, 1922.)

FOREIGN

Exports of Soap, Oils and Fats from Germany

Official statistics give the German exports of soap, oils, fats and related products during the first quarter of 1922 as follows:—

	Jan.–Mar., 1922 Metric tons	Mill. mk
Soaps:—		
Soap in cases and jars ..	1817·9	63·2
Hard soap, solid creolin, fat lye powder, etc.	143·1	2·7
Soft-soap, liquid creolin, etc. ..	348·7	6·9
Toilet soap, alumina soap, etc. ..	467·4	11·6
Total	2772·1	84·4
Related products:—		
Polishes etc.	546·6	16·9
Glycerin and soap by-products ..	263·2	14·2
Cart grease	76·1	0·3
Lubricants prepared with oils or fats	600·7	8·4

The total export of soap in 1920 was 4121·5 t., valued at 55·7 million marks. Danzig, Memel, the Saar district, Luxembourg, Switzerland, and other adjacent States are the chief markets for German soap products.

Dyes in the Red-Sea District

Prior to the war over 800,000 lb. of dyes, valued at £38,000, was imported annually into the Red-Sea district through Aden. The dyes were chiefly lac scarlet, vegetable indigo and saffron from India, but Germany supplied all the aniline red and synthetic indigotin. Following the war, importations declined to 162,671 lb. in 1919–20, but improved to 528,503 lb. in 1920–21, the shipments originating as follows:—Aniline red: Bombay 198 lb., United Kingdom 1296 lb., Austria 3248 lb. Lac scarlet: India 473,872 lb. Vegetable indigo: India 25,984 lb. Synthetic indigotin: Austria 10,524 lb., Belgium 3248 lb. Saffron: India 133 lb. Germany is reported to be regaining a footing in this market.—(*U.S. Com. Rep., June* 12, 1922.)

German Exports of Red Lead, Zinc Dust, and Bronze Powders from January to March, 1922

Destination	Red Lead	Zinc Dust	Bronze Powders
		Metric tons	
Austria	159·1	70·1	—
Belgium	—	119·8	7·1
Czechoslovakia	172·1	—	—
Denmark	32·1	—	3·1
England	—	—	17·4
France	—	—	9·5
Holland	93·9	1466·2	9·8
Italy	—	—	19·7
Spain	—	—	2·9
Sweden	57·8	19·4	2·2
Switzerland	—	—	9·6
S. E. Asia	79·3	—	—
United States	—	—	122·4
Other countries	374·5	508·4	39·6
Total	968·8	2183·9	243·3
Value. mill. mk.	25·1	24·6	28·3

The total amount and value of the exports of the above products during 1920 were:—Red lead, 3370·4 t., 35·3 mill. mk.; zinc dust, 4261·2 t., 19·3 mill mk.; bronze powders, 832·7 t., 49·9 mill mk.

GOVERNMENT ORDERS AND NOTICES

Export of Fertilisers.—The Board of Trade has issued an open general licence authorising the exportation to all destinations of basic slag; superphosphate of lime; and manures, compound, containing either basic slag or superphosphate of lime.

Phosphate Deposits in Morocco.—A copy of the *Bulletin Officiel* (No. 503, June 15), containing a report on the work of the Sheerifien Office of Phosphates during 1921, may be consulted at the Department of Overseas Trade, 35, Old Queen Street, S.W. 1.

Chemical Works Regulations, 1922.—The Home Secretary has issued Regulations for chemical works dated July 11, 1922, which constitute the final form of the draft Regulations issued in December, 1920, and in March, 1922. Copies may be obtained from H.M. Stationery Office, price 4d.

Safeguarding of Industries Act.—*Part I.*—The Board of Trade has received a complaint under Section I (5) that acetic acid of 80 per cent. grade or higher has been improperly excluded from the lists of dutiable articles. The complaint will be submitted to the Referee, and any person directly interested should communicate immediately with the Assistant Secretary, Board of Trade (Industries and Manufactures Department), Gt. George St., S.W.1.

International Exhibition of Liquid Fuels in Paris.—This exhibition, which is being organised by the Société de Chimie Industrielle in connexion with an International Congress on Fuels (October 9—15), will be held in Paris from October 4 to 15. Applications for space should be made to Monsieur J. Gérard, Commissaire Général, 49, Rue des Mathurins, Paris, and all particulars can be obtained from the Department of Overseas Trade (Exhibitions and Fairs Division), 35, Old Queen Street, S.W.1.

REVIEWS

(1) Engineering Steels. *By* Leslie Aitchison. *Pp.* xxxii.+390. *London: Macdonald and Evans*, 1921. *Price* 25*s. net.*

(2) Metallography. *By* C. H. Desch. *Text-books of Physical Chemistry, edited by Sir W. Ramsay and Prof. Donnan. Third edition. Pp.* x+440. *London: Longmans, Green and Co.*, 1922. *Price* 16*s. net.*

(1) This book is published in the Reconstructive Technical Series, the aim of which is to diffuse the new knowledge and enlarged technical skill gained during recent years and so make it available for the practitioner of to-day, as a means towards greater all-round efficiency and increased competitive power in the world's markets. The series is published under the editorship of G. W. de Tunzelman. Each volume is designed to serve a particular trade or vocation, the present volume dealing with steels from the engineer's point of view and providing the information which the engineer should possess in order to enable him to understand the steels which he is using. Prof. W. C. Unwin has written the foreword in which he compares modern requirements with those of the days of wrought iron. The developments in engineering practice during the last twenty years have resulted in the necessity for steels capable of performing higher duties than the older-fashioned plain carbon steels, and the requirements of the automobile and aircraft industries in particular have created a demand for steels possessing high orders of mechanical properties. This demand for high-quality steels has led to extensive inspection and the compilation of many specifications. The earlier specifications merely aimed at securing stipulated mechanical test results but the modern requirements must necessarily include correct chemical composition and correct heat treatment.

The purely metallurgical portions of the subject are dealt with very briefly; for instance, steel-making processes occupy fifteen pages, and this chapter seems a little unbalanced as more than five of these pages are devoted to the Bessemer process which is of minor importance in connexion with the type of steels mainly dealt with in the book.

The casting and working of steel receive attention, the solidification of molten steel in ingots being followed out in detail together with the nature of the crystallisation which takes place and its bearing on the properties of the resulting metal. This is of particular importance for its bearing on the position of planes and zones of weakness in the ingot, which may become the centres of definite defects. The effect of work, such as forging, on the crystals situated in different parts of the ingot and on the mechanical properties of the steel is described.

The chapter devoted to the heat treatment of steel occupies fifty pages, the thermal equilibrium diagram of the iron-carbon system and the effect of alloying elements on the hardening of steel receiving attention. Mass and volume effects in heat treatment and the engineering value of hardened and tempered steels are also discussed. The methods used for the mechanical testing of steel receive considerable attention as it is recognised that the metal will finally be judged by its mechanical properties, and from the engineer's point of view the details of composition, heat treatment, etc. are only of secondary value. The tests which have recently become so important to the engineer, such as hardness, impact, alternating stress, and other tests are dealt with and the mechanical properties of steel are described, the definitions of the British Engineering Standards Association for elastic limit and yield point being used. A chapter is devoted to plain carbon steels in which the effect of varying carbon, high and low manganese, mass, etc. is described and followed by details of the mechanical properties of certain steels of selected compositions. A separate chapter is devoted to the important subject of alloy steels, and in this a classification is used based on the maximum stress obtainable with the steels. Steels with air-hardening properties are described in detail. Nickel-chrome steels receive most attention, but nickel, chrome-vanadium and "stainless" or high chromium steels are also described.

Case-hardening is of considerable importance to the engineer, especially for the lighter forms of machinery, and the operation itself, the carburising mixtures, the temperature necessary, the steels suitable, and the after-treatment of the case-hardened parts receive attention. The influence of cold work on the mechanical properties of steel is of greater importance than is generally realised, and cold worked material, in the form of bright drawn bar, is largely used in the manufacture of comparatively unimportant parts, particularly those in automatic machines. The changes in mechanical properties produced by varying amounts of cold work and also by reheating to temperatures below the critical range, that is, in the operation of blueing, are illustrated by tables and curves. The concluding chapter deals with tool steels, and in this chapter it appears that a disproportionate amount of attention has been given to plain carbon tool steels and too little to self-hardening and high-speed steels.

The book contains fourteen appendices, on such subjects as the influence of sharp corners and scratches on mechanical properties, Young's modulus of elasticity, the properties of steels at high temperatures, various classes of machines for impact testing, determination of hardness; and the last one consists of a bibliography of original papers on the hardness of metals. It is illustrated by a number of photomacrographs and photomicrographs showing crystalline structure of ingots, defects met with in ingots and forgings, effect of heat treatment and similar subjects; it is a pity that among such an excellent series of photographs, a very poor hand-drawn representation of pearlite has been inserted.

This book should prove to be very useful to engineers requiring a knowledge of the possibilities of modern steels and to metallurgists requiring definite knowledge of the more recent methods of testing metals. The subject could have been treated from a somewhat broader point of view, as it must not be forgotten that the engineer has many requirements not covered by aircraft and automobile specifications, which appear to constitute the chief interests of the author.

(2) This third edition of Professor Desch's well-known book on metallography will be welcomed by all interested in the subject because in it the most important results of recent investigations and references to recent publications have been incorporated. The last edition appeared in 1913; since then the demands for the book have been met by a new impression of the second edition, published in 1918. The most important changes have been made in the chapters dealing with the physical properties of alloys, with corrosion and with the metallography of iron and steel. With reference to the physical properties of alloys, further information is added on hardness, a subject which has received considerable attention during the last few years. The subject of corrosion also receives further treatment, the work of the Corrosion Committee of the Institute of Metals being specially referred to. In the chapter on the metallography of iron and steel, the results of the study of the space lattices by the X-ray method have been added. The actual amount of new material in this edition is not great and its increased value is due to small additions and modifications together with references to the latest work. There is probably no one with a better knowledge of the literature of the subject than the author, and his tables of alloy systems contained in the appendix of 24 pages are probably more frequently referred to by metallographers than any other published matter on the subject.

C. O. BANNISTER.

INORGANIC CHEMISTRY. *By* T. MARTIN LOWRY. *Pp. x+943. London: Macmillan and Co., Ltd., 1922. Price 28s. net.*

To everyone engaged in teaching senior students the appearance of a new book on advanced inorganic chemistry by an author of reputation is an event of very real interest. For in spite of all the developments of chemical science inorganic chemistry must remain common ground to all chemists, and no chemical education can exclude the study up to a certain point. It is, however, becoming always more difficult to fix the reasonable limits and to assort from the overwhelming mass of material such a body of facts as should be brought to the notice, and to a large extent be established in the memory, of the student. There is also the difficulty of deciding how much of the general theory of chemistry, which in recent times it has been the growing habit to detach as "physical chemistry," should be elucidated in connexion with the facts, processes and applications of inorganic chemistry. There is here a great demand on the sense of proportion of the author and, be it added, on the consideration of his critics. Finally when the selection has been made there remains the crowning task of presenting the material with the utmost lucidity, coherence, and interest attainable within the limits of a book of marketable price.

Professor Lowry has evidently taken very great pains with his book, he has secured valuable assistance from a number of highly competent authorities and he has achieved his task in rather less than a thousand well-written, well-printed, and well-illustrated pages. As soon as the book appeared the present writer read the first 200 pages and has since devoted many short periods to sampling the rest. As the result he is inclined to rate the book very highly indeed, and—though he awaits the experimental trial with students for a final judgment—to place it as a strong competitor for the first place among all books that attempt the same object, subject only to the price not proving prohibitive.

It is not easy to state fully the grounds on which this judgment is based, but they are mainly two; first that Dr. Lowry exhibits what seems to be a very wise choice of material and secondly that he gives the impression of having not merely assembled it but of having exercised a critical judgment upon it and given to a great deal of it the impress of his own mind. It is inevitable that there should be the defects incidental to a necessary compression. So far as the historical side is concerned this is fully compensated by the fact that it drove the author to publish separately his Historical Introduction to Chemistry, a book of high and enduring value. But the physical chemistry of the present volume is so compressed that much of it can only rank as a reminder of what must have been learned, under more degrees of freedom, elsewhere. One can see also how the author has been under constraint in his excellent handling of practical applications. But to get an idea of what confronts the writer of a text-book on inorganic chemistry to-day consider for example what you are to do with iron. Think of the advance of knowledge in thirty years! What are you to say about its metallurgy—what about the various steels—are you to say that gamma iron differs from the alpha and beta forms in being constructed on a face-centred cubic lattice—and if you do, are you to elucidate the statement? At every point facts that you would like every student to know stand in queues, waiting for admission, in no clearly rightful order of precedence.

Professor Lowry has adorned his book with a number of beautiful pictures of minerals. They will have the effect of stirring the memory and exciting a salivary flow in those who have been nurtured and subsist on a less splendid mineral diet than is here portrayed. But to those who have not seen the things at all in reality, what is really to be got from these pictures? Perhaps Dr. Lowry will consider the advisability of replacing in a future edition some at least by the beautiful microphotographs of Sir George Beilby's recent book.

Very few minor errors have been noticed and no really indictable offences of commission or omission have obtruded themselves during this first examination. On the question of price it is to be hoped that the publishers are competent judges and that Professor Lowry's book may be put to the extended trial that it certainly deserves.

ARTHUR SMITHELLS.

BEITRÄGE ZU EINER KOLLOIDCHEMIE DES LEBENS. *By* DR. RAPHAEL ED. LIESEGANG. *Second edition, revised. Pp.* 39. *Dresden and Leipzig: Theodor Steinkopff*, 1922. *Price, paper*, 1*s*. 2*d*.

This pamphlet discusses the bearing of colloid chemistry upon the problems of its relations to living matter. The pamphlet begins with an introductory section on diffusions, followed by five different sections under the following heads:—(2) Diffusions with chemical exchanges, (3) Lime precipitation in gelatin gels, (4) Stratified structures, (5) Crystalisation in gels, and (6) Dissimilation, assimilation, and membrance action. The author has, on the whole, treated the subject with clearness, the material is well selected, and references to the literature are given where neceessary. It will undoubtedly prove a useful and interesting summary to all those seriously interested in the subject.

DINSHAW R. NANJI.

CHEMISTRY OF RADIOACTIVE SUBSTANCES. *By* A. S. RUSSELL. *Pp.* xi+173. *London: John Murray*, 1922. *Price* 6*s. net.*

Dr. Russell has written an "Introduction to the Chemistry of Radioactive Substances" in a series of 12 chapters covering about 170 pages. It is perhaps a sign of the way in which this subject has developed that the present volume, instead of being a monograph, with detailed references to almost every paper that has been issued, takes on the familiar form of an elementary text-book, and does not profess to do more than provide an introduction to the study of the subject.

Dr. Russell possesses in a special degree the two qualifications that are needed to make a success of such an enterprise, namely, a complete knowledge of the subject with which he has to deal and considerable experience in explaining scientific phenomena to non-technical readers. In this volume he has fulfilled in an excellent way the task he has set before him, and, although the student must look elsewhere for references to serve as an index to the original literature, he will, after mastering Dr. Russell's book, have obtained a knowledge of the subject which is amply sufficient for any chemist who does not propose to undertake original work in this field.

REVIEW

Vol. XLI] SEPTEMBER 15, 1922 [No. 17

CHEMISTRY AT THE BRITISH ASSOCIATION: HULL, 1922

At the ninetieth meeting of the British Association for the Advancement of Science, held in Hull from September 6 to 13, Prof. J. C. Irvine, F.R.S., Principal of St. Andrews University, delivered the presidential address to Section B (Chemistry). The following abstract of this address was prepared under the author's supervision, and the succeeding abstracts are those of papers presented to the same meeting by workers in Principal Irvine's laboratories.

PRESIDENTIAL ADDRESS TO SECTION B

ART I—The Organisation of Research

LOOKING back on the sixty-nine years which have elapsed since the British Association last met in Hull, it is vident that, in the interval, a revolution has aken place in the public and official attitude owards scientific research. The change has ome rapidly, but it was not spontaneous. Many years had to be spent in disseminating he idea that scientific research is a vital ecessity, and toward this end Presidents of he British Association have added the weight f their influence and eloquence. Although any other factors have doubtless played a art in creating a research atmosphere in this ountry, the work of the British Association as not been the least important.

Scientists have been given the opportunities hey desired now that the State, acting through he Department of Scientific and Industrial esearch, provides facilities for graduates to ake a part in advancing scientific knowledge. hemistry bulks largely in each of the research ganisations operative in this country, and e future of our subject is intimately connected ith their success or failure. We are at the ginning of a new phase in research, which s become a unit in our national scheme of ucation, and chemists must not forget that consequence fresh responsibilities devolve on them. By their own efforts they must stify what has been done.

The Government grants are awarded gener- sly and widely, and there is a rush to chemical search in our Colleges, but no matter how eat the enthusiasm and ability of these young aduate workers, they have to be trained, ided and inspired, if their research period to be spent to the best advantage. Help of s kind can come only from the man of mature ars and experience, and the duties of such upervisor cannot be light. He must possess rsatility, must command the ready sympathy and understanding which enable him to enter into the beginner's difficulties, and he must avoid the temptation to use the research student as a scientific labourer.

Experience has shown that young research graduates require firm handling, and that constant effort is necessary to secure that they work in a business-like manner, keep proper records, and avoid extravagance and waste. The fulfilment of these requirements absorbs the main energies of the research supervisor, who is called upon to sacrifice his leisure and, in large measure, his own private research. The success of the scheme will be imperilled if our Universities and Colleges fail to realise this and are unprepared to afford members of the professor or lecturer class, who join in the movement, relief from formal teaching and administrative duties. Otherwise, we shall have made the mistake of focussing unduly on the research apprentice to the neglect of the interests of the mature investigator.

To secure these ends it is suggested that, in each institution, there should be a board or standing committee entrusted with the supervision of research. The functions of such a body would be widely varied and would include :—

1. The allocation of money voted specifically from university or college funds for research purposes.
2. The power to recommend additions to the teaching staff in departments actively engaged in research.
3. The recommendation of promotions on the basis of research endeavour.
4. The supervision of regulations governing higher degrees.

Among the more specific problems which would confront such a Board are :—

1. The creation of research libraries where reference works can be consulted immediately.
2. The provision of publication grants, so that where no periodical literature is available, the work will not remain buried or obscure.
3. The allocation of travelling grants to enable workers to visit libraries, to inspect manufacturing processes, and to attend meetings of the scientific societies.

PART II—Some Research Problems in the Carbohydrates

CELLULOSE—STARCH—INULIN

Twenty years ago, the first paper on the alkylation of sugars was given by Purdie and Irvine to the meeting of the British Association in Belfast. The principles then communicated have since proved of wide application in furnishing well-defined evidence of the structure of sugars and their derivatives, so that one by one the natural groups of carbohydrates have been studied by this method. As a result, ideas regarding the constitution of these compounds have become more secure and more definite. Simple sugars, glucosides and disaccharides have all been brought under review, and the results now submitted justify the application of structural formulæ to cellulose, starch and inulin.

CELLULOSE

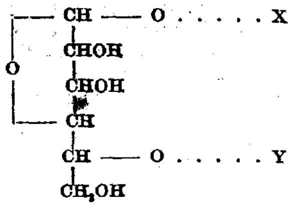
(*with W. S. Denham and E. L. Hirst*)

The difficulties which stand in the way of ascribing a molecular constitution to cellulose are too numerous to mention, but the stability of the complex, coupled with its limited solubility and lack of volatility, are outstanding obstacles. Although it is obvious that real progress can come only as a result of patient and systematic research, and that impetuous theorising does infinite harm, many suggestions have nevertheless been put forward to represent the polysaccharide structurally.

A necessary preliminary to speculation on the formula of cellulose is to ascertain if the aggregate $(C_6H_{10}O_5)_n$ is composed entirely of glucose units. The required evidence has been obtained, as cotton cellulose has been converted into pure crystalline methylglucoside, the yield of which is 95 per cent. of the theoretical amount. Structures which are unrelated to glucose can therefore be disregarded and the various formulæ for cellulose may be appropriately divided into three classes :—

1. Constitutions modelled on that of the glucosides, involving the addition of numerous glucose residues by mutual condensation. According to this view, cellulose consists of large molecules.
2. The unit of cellulose may be regarded as a simple anhydro-glucose, $C_6H_{10}O_5$, highly polymerised.
3. The unit has been claimed to be a simple anhydro-*n*-saccharide (where *n* is a small multiple), polymerised in unknown numbers.

In 1910 Dr. W. S. Denham succeeded in alkylating cellulose and obtained a derivative containing 25 per cent. of methoxyl. This, on hydrolysis, yielded a mixture of methylated glucoses from which 2.3.6.-trimethyl glucose was isolated. Denham's work thus gave the first clear evidence as to the linkage of part of the cellulose molecule which must contain the unit :—



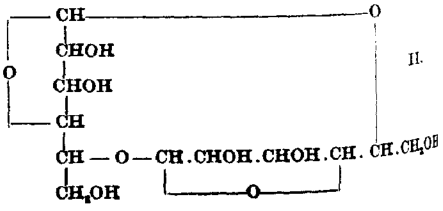
I.

His research left unexplained the nature of th residues X and Y, and the investigation wa therefore, continued. In consultation wit Dr. Denham, we find that the exhaustiv methylation of the polysaccharide, when repeated twenty times, gives a product containing 43·0 per cent. of methoxyl in place o 45·6 per cent. required for a trimethyl-derivative. The carbon and hydrogen values als agree with the formula $(C_6H_7O_2(OMe)_3)_x$ and as the material preserved a fibrous structure there is little likelihood that profound molecula alteration had taken place. The trimethy cellulose was then submitted to simultaneou depolymerisation, hydrolysis, and conversio of the scission products into the correspondin methylglucosides. These were distilled in high vacuum, the total yield obtained bein 90 per cent. of the theoretical amount. Th distilled material consisted of 2.3.6-trimethy methylglucoside and *no trace of tetramethy methylglucoside was present.*

On hydrolysis of the distilled glucoside, a 89 per cent. yield of crystalline 2.3.6.-trimethy glucose was obtained showing $[\alpha]_D$ +108° → +67·0°. *No isomeric trimethyl glucose wa present : higher and lower methylated glucose were absent.* The reactions involved in th research are shown below, and considering th nature of the operations involved the yield may be claimed to be quantitative.

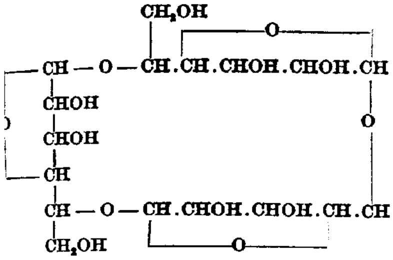
Cellulose
↓
Trimethyl cellulose } Yield 90%
↓
2.3.6–Trimethyl methylglucoside
↓ } Yield 89%
2.3.6-Trimethyl glucose

The scheme affords a proof that all the glucos residues in cellulose are identical in structur and have the hydroxyl groups 2, 3, and 6 unsubstituted. To satisfy this condition and t account for the formation of cellobiose, it i necessary to include in the formula at least tw glucose residues. This is fulfilled by th structure II.



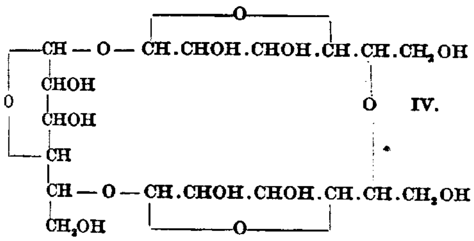
II.

In terms of the above, 100 parts of cellulose should give 105·5 parts of cellobiose, and here the difficulty is encountered that the yields of this disaccharide are extremely variable and rarely exceed 35 per cent. The highest claimed is of the order 50—60 per cent. and, in the meantime, it is prudent to select a formula for cellulose which will give a result only slightly higher than this figure. We, therefore, propose the symmetrical tri-1.5-anhydro-glucose for the unit of cellulose on the ground that this structure would give a 70 per cent. yield of cellobiose as the theoretical maximum.



III.

There is, however, an alternative method of coupling the glucose residues and this gives the structure shown below :—

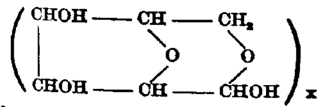


IV.

Taking into account the fact that it can yield only one disaccharide, we prefer Formula III. The essential properties of cellulose, so far as they are displayed in chemical reactions, are accounted for by both formulæ.

Various formulæ which have been previously suggested for cellulose are excluded by the results now submitted. Selected examples are :—

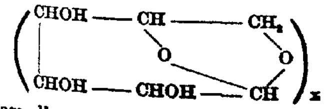
Green's formula :—



V.

which would give a trimethyl cellulose and, on hydrolysis, would be converted into 3.4-dimethyl glucose of the amylene-oxide type.

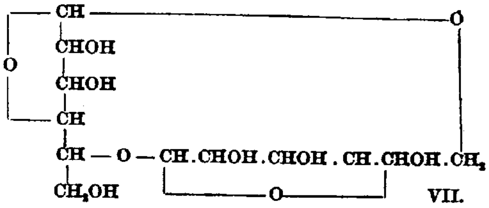
Vignon's formula :—



VI.

is equally unsatisfactory in that the final product should then be 2.3.4-trimethyl glucose of the amylene-oxide type.

The formulæ proposed by Tollens, Cross and Bevan, Bartelemy and Pictet are unsuitable for similar reasons. It is also possible to dispose of Karrer's formula which is that of an anhydro-cellobiose (termed " cellosan ")



VII.

A compound possessing this structure would yield on methylation and hydrolysis:—

1 molecule of 2.3.5-trimethyl glucose,
and 1 molecule of 2.3.6-trimethyl glucose.

Our experimental evidence is completely opposed to this view.

An entirely different type of formula for cellulose has been proposed by Hess, who regards the polysaccharide as a complex glucoside. The feature common to all such glucosidic formulæ is that the hydroxyl groups are not symmetrically distributed in the glucose residues. The simplest structure suggested by Hess would give, by our processes, five molecules of 2.3.5.6-tetramethyl glucose and one molecule of glucose, whilst his more elaborate molecules would produce these same compounds together with trimethyl glucose. The reactions of trimethyl cellulose exclude all formulæ of this nature.

STARCH

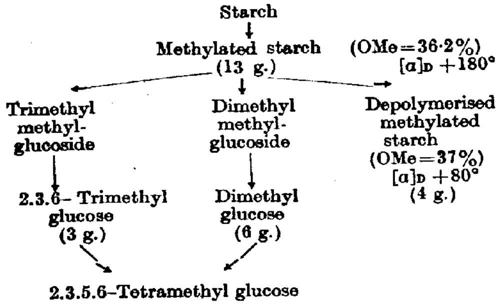
(*with John Macdonald*)

Turning to the problem of the constitution of starch, we encounter very much the same difficulties as have already been referred to under the heading of cellulose. At the present time there is little tendency to regard starch as a highly complex glucoside in which a large number of hexose residues are mutually condensed together, and the view prevails that the polysaccharide is derived from a comparatively simple anhydro-sugar by profound polymerisation. Attention may be focussed on three formulæ based on such ideas.

The unit of starch has been claimed to be :—

1. β-glucosan	(Pictet).
2. anhydro-maltose	(Karrer).
3. triamylose	(Pringsheim).

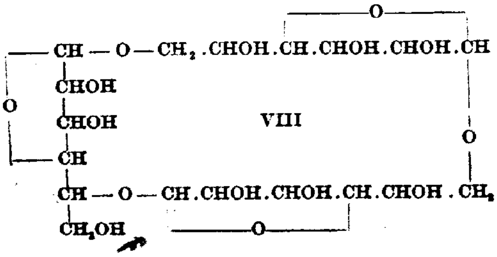
It is possible to test these views by the methylation method. When the polysaccharide is methylated repeatedly the reaction ceases when the methoxyl content is 37 per cent. Now, this value for methoxyl corresponds exactly with the theoretical amount calculated on the basis that one hexose residue has acquired three methyl groups whilst four are shared by two glucose residues. Ultimate analysis is also in agreement with this view. Hydrolysis of the methylated starch has shown that this is not a fortuitous coincidence, and we thus obtain a direct clue to the magnitude of the unit which goes to form the starch molecule. When digested with methyl alcohol containing hydrogen chloride, the methylated polysaccharide was converted into trimethyl methylglucoside and dimethyl methylglucoside. These were separated by distillation in a high vacuum and thereafter hydrolysed to give the parent sugars. A totally unexpected result was encountered in that the trimethyl glucose isolated proved to be the crystalline form in which the methyl groups occupy the 2.3.6-positions. One glucose-residue in starch must thus be substituted as shown in Formula I., and must have the linkage characteristic of cellulose. In order to accommodate the formation of maltose from starch, either one or two additional glucose residues must be present at X and Y in the unit, but before developing a formula which will fulfil the above conditions, an outline of the reactions involved may be given :—



Starch
Methylated starch (13 g.)
(OMe=36·2%) [a]D +180°
Trimethyl methyl-glucoside
Dimethyl methyl-glucoside
Depolymerised methylated starch (OMe=37%) [a]D +80° (4 g.)
2.3.6– Trimethyl glucose (3 g.)
Dimethyl glucose (6 g.)
2.3.5.6–Tetramethyl glucose

It will be seen that the removal of trimethyl glucose and dimethyl glucose in the molecular ratio of 1:2 is effected without alteration in the *composition* of any methylated starch which survives hydrolysis.

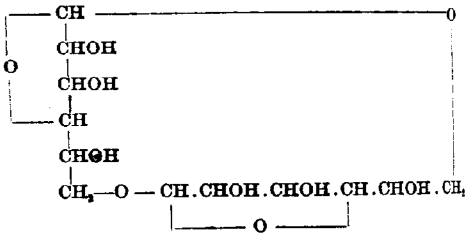
Four different structures may be built up to accommodate the formation of maltose and the results afforded by methylation. These possible formulæ differ in an important respect in that maltose may be obtained in two ways from one of the structures, and in only one way from each of the others. Pending the completion of further work on this subject, we prefer the Formula VIII. :—



The above constitution postulates that starch is derived entirely from the butylene-oxide form of glucose, and this we have shown experimentally to be the case.

Two objections to the molecular unit proposed may be discussed. In the formation of maltose no more than one molecule of this disaccharide could be obtained from one unit. The maximum yield of the sugar, without making allowance for any synthetical action of the enzyme, would therefore be of the order 70 per cent. (74 per cent. calculated as maltose hydrate). Another objection to the new structure is that the acetolysis of starch might result in molecular rupture in such a manner that cellobiose would be produced. So far, this disaccharide has not been encountered in the degradation products of starch, a result which is not surprising in view of the uncertainty attending the isolation of cellobiose.

It is perhaps advisable to point out that the experimental results now presented demand the rejection of various formulæ for starch proposed from time to time by Karrer. His structures are based on a diamylose (anhydro-maltose), two formulæ for which have been put forward, differing in the position of the anhydro-ring. The unit he prefers at present is :—



and it is clear that the only trimethyl glucose to which such a structure could give rise is the 2.3.5-form described by Irvine and Oldham. No trace of this compound was detected by us and, moreover, the 2.3.6-variety of trimethyl glucose actually obtained cannot possibly be accommodated by Karrer's formula. For similar reasons, it can no longer be maintained that starch is an aggregate of β-glucosan residues.

INULIN

(*with Ettie S. Steele, G. McOwan, and M. I. Shannon*)

Inulin is derived from fructose and, until recently, there was no reason to doubt that the parent hexose was the well-known lævorotatory form of the ketose. This view is no longer tenable as, although inulin itself yields the normal form of fructose on hydrolysis, trimethyl inulin is converted into a *dextro-rotatory* trimethyl fructose. In similar manner, dimethyl inulin gives a *dextro-rotatory* dimethyl fructose. Each of these alkylated ketoses was proved to be a derivative of the γ-fructose which is a constituent of sucrose.

This result places inulin in a position which is unique, and the evidence is conclusive that the polysaccharide is entirely composed of γ-fructose residues, each of which retains three hydroxyl groups. One important point left unsettled in previous papers on this subject was whether the trimethyl γ-fructose obtained from trimethyl inulin is a single chemical substance or a mixture of isomerides. The experimental difficulties in the way are formidable, as methylated fructoses of the γ-type are liquids and give no crystalline derivatives. By the following method, however, it has been established that only one form of trimethyl fructose is produced from inulin.

Trimethyl inulin was digested with methyl alcohol containing hydrogen chloride under conditions which effected (*a*) depolymerisation, (*b*) hydrolysis, (*c*) condensation, to give trimethyl methylfructoside. The product was distilled in a high vacuum and fractions were abstracted at frequent intervals while the boiling point remained constant. All the fractions showed the same refractive index and specific rotation. Moreover, the speed of hydrolysis of the fructoside was in each case the same, and in each experiment the trimethyl fructose then formed showed identical physical constants. Of greater importance is the fact that all the specimens of trimethyl methylfructoside reacted in the same way when dissolved in acetone containing hydrogen chloride. Under these conditions, trimethyl fructosemonoacetone was formed, and here again the speed of the reaction showed no difference in any of the specimens.

There can be no doubt, therefore, that inulin is an aggregate of anhydro-γ-fructose residues and that each of the units is identical. As the exact structure of the methylated fructoses of the γ-type is not yet determined with certainty it is premature to speculate on the manner in which these residues are united, but the subject is engaging our attention.

* * *

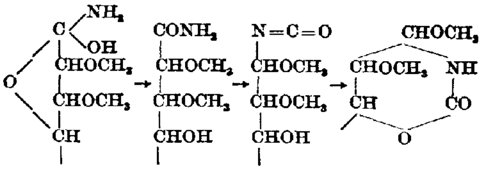
Looking at the position which has been reached, it may be said that the polysaccharides, like many other fields of research, are after all not so complicated as they appeared when viewed from afar. The close relationship now established between cellulose and starch, starch and lactose, inulin and sucrose will, it is hoped, play a part in bringing within the range of exact experiment the structural study of all types of natural compounds related to the simple sugars.

A New Type of Nitrogenous Sugar Derivative

By J. Pryde

In extending his studies of the action of sodium hypochlorite on amides of α-hydroxy acids, Weerman applied his reaction to the amides of simple hexonic acids and so devised what has proved to be the best practical method of degrading hexoses to pentoses. In the present communication the results of applying this degradation method to a fully methylated hexose are given. The investigation was originally undertaken in the hope that a propylene-oxide form of a methylated arabinose would be obtained in place of the normal butylene-oxide type, or alternatively that the intermediate compounds would be isolated and thus elucidate the course of the reaction as applied to the sugar group.

Tetramethylglucose was oxidised to tetramethylgluconic acid, which was isolated as its internal lactone. The lactone, dissolved in absolute alcohol, was treated with dry ammonia and the amide was isolated in a crystalline condition. Evidence is available to show that this compound does not possess the structure of a true acid amide, but exists in the form of an aminolactone. On subjecting the amide to the action of cold alkaline hypochlorite a crystalline body of the composition of the intermediate isocyanate was obtained and from its behaviour the constitution of an internal urethane has been assigned to it. The reaction proceeds as follows:—



The formation of this intermediate urethane affords striking evidence of the stabilising effect of methyl groups in the sugar chain. It is also interesting in showing the conversion of a carbohydrate into a derivative in which nitrogen is present in a stable cyclic substituent.

The Preparation and Constitution of Synthetic Fats containing a Carbohydrate Chain

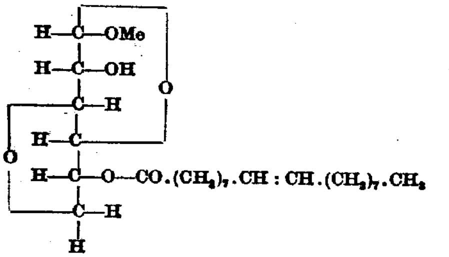
By Helen Simpson Gilchrist

The products obtained when a carbohydrate chain is coupled with the unsaturated groups characteristic of natural fats have been studied with the object of establishing the constitution of the synthetic fats thus formed.

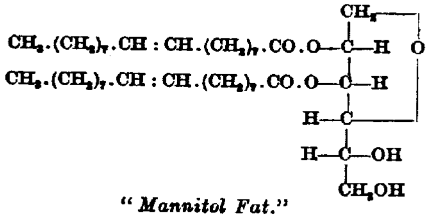
As shown by Lapworth and Pearson, α-methylglucoside and mannitol both combine, on heating in the presence of sodium ethoxide, with the oleyl residues of olive oil, thereby liberating glycerol. The present research has proved that a mono-oleate is initially formed in the first case, whilst in the second two oleyl groups enter the hexitol chain. This condensation is immediately followed by internal dehydration, the carbohydrate chain in each case losing one molecule of water, and the fatty residues remaining intact.

Anhydro-methylglucoside mono-oleate and mannitan di-oleate are definite chemical individuals. On methylation they yield monomethyl derivatives, which are unstable in the high vacuum of the Gaede pump. On being heated with acid alcohol, these methylated compounds both give methyl oleate, together with an alkylated sugar derivative. In both cases the anhydro-ring in the molecule persists during hydrolysis and thus a passage is opened into the series of anhydro-sugar derivatives and alcohols.

Examination of the above cleavage products confirms the views already held regarding the mechanism of the reactions discussed, and complete structural formulæ are assigned to the original "methylglucoside" and "mannitol" fats.



"*Methylglucoside Fat.*"



"*Mannitol Fat.*"

THE SIGNIFICANCE OF CRYSTAL STRUCTURE*

SIR WILLIAM BRAGG

A CRYSTAL can be considered as built up by the repetition through space of a unit of pattern. The unit preserves throughout its internal character, its orientation, and its relations to neighbouring units. There is a minimum value for the volume of the unit, and its form is definite; but its boundaries may be chosen in different ways. For instance the smallest portion of a crystal of rock salt which fulfils the definition of a unit is a cube whose edge is 5·62 Angström units: and its corners may coincide either with chlorine atoms or with sodium atoms. We may call such a unit the "crystal unit."

The crystal unit contains every kind of atom or bond, every feature, and every property which the crystal possesses as a whole. If we investigate the physical properties of the crystal we investigate the physical properties of the unit. If we can discover the number and the arrangement of the atoms within the unit we may hope to discover also the part which each atom plays in forming the characteristics of the whole. The methods of X-ray analysis tell us very readily the number of atoms in the unit, and are throwing more and more light on their arrangement.

This mode of progress has its analogies in the history of physics and chemistry. Some of the properties which substances possess are also possessed by the individual atoms or molecules of which they are composed. In the main the properties are those which are displayed when the substance is gaseous or liquid: when, in fact, its atoms or molecules are not linked together into crystalline form. Progress has followed on the discovery of the constitution of the smallest portion of the substance, molecule or even atom, which displays in full the properties referred to. As far as possible the part played by each atom in the molecule is then laid bare. The further this analysis is carried, the more does it become possible to carry out the reverse process, and to design, or it may be to construct, a substance having any desired characteristic.

The general limitation to the properties of gases or liquids is really severe. We remove it when, by the aid of X-ray analysis, we examine the structure of the crystal unit, because the unit displays all the properties of the solid. A crystal has elasticities, thermal expansions, thermal and electric conductivities, dielectric capacities, optical activities, and all these not only as scalars but as vectors. Quartz, to take a simple instance, has many properties as a crystal: all of them are displayed also by the crystal unit of quartz, that is by three molecules of SiO_2 arranged in a particular way. They are not characteristic of the separate molecule of SiO_2, still less of the separate atoms of silicon or oxygen. When we know the exact arrangement of the nine atoms in the unit, we can apply all that we know about quartz to this small group. In this way a wide field of research opens out, in which the crystal unit plays a part like that of the molecule in other fields, and the magnitude of the results may be just as great.

So far as X-ray analysis of the crystal unit has progressed in the few years since its inception, it has followed the natural course. Some property of the whole substance is considered as capable of explanation by what is to be found within the unit. The first property to be treated in this way was that of form or symmetry, one of the most striking of crystal characteristics. In fact many of the first determinations of crystal structure were made by the aid of the principles of symmetry with a very little, but very necessary, assistance from the X-ray analysis. In the case of rock salt, for example, the symmetry is that of a cube, and of the highest class of cubic symmetry, so that, as soon as the analysis had assigned four molecules to the crystal unit, and had shown also certain differences in the spectra of the isomorphous substances NaCl and KCl, the structure was determined completely. Even with more complicated structures, considerations of symmetry are of great assistance, for they limit the number of possible configurations. Many instances are to be found already in the short history of X-ray analysis.

---

* An abstract of papers delivered before Sections A and B of the British Association, Hull, 1922.

When the symmetry of the crystal is considered as belonging also to the unit, and when at the same time the number of atoms or of molecules in the unit is known, very interesting deductions may be made concerning the symmetries of the atoms or molecules themselves. We may take a simple example from an organic crystal. Naphthalene belongs to the monoclinic prismatic class, that is to say, it has an axis of digonal symmetry and a plane of symmetry at right angles to it. There are two molecules in the unit. If the molecule had no symmetry of its own, the symmetry of the unit could not be achieved by the use of two molecules only; four would be required. We might imagine ourselves constructing the crystal with reference to a given axis and a given plane of reflection perpendicular thereto. We place one molecule in position, and a second so that it is the reflection of the first: then we turn the pair about the axis through 180° and so find the positions of the third and fourth molecules. Since only two molecules are required, not four, we conclude that the naphthalene molecule has already a degree of symmetry. If it has a plane or centre of symmetry, the latter of the two operations described is sufficient; the former, if it has a centre of symmetry, or a digonal axis. In mathematical terms, if the molecule has symmetry represented by $[(x, y, z,)\ (x, -y, z,)]$ *i.e.*, a plane of reflection, the digonal rotation adds $[(-x, y, -z,)\ (-x, -y, -z,)]$; if it possesses a centre of symmetry as represented by $[(x, y, z,)\ (-x, -y, -z,)]$ or digonal symmetry $[(x, y, z,)\ (-x, y, -z)]$, then reflection adds $[(x, -y, z,)\ (-x, -y, -z,)]$. The result is always the four-point symmetry of the monoclinic prismatic class, as already described.

It seems almost certain that we can go further than this and say that the naphthalene molecule has no more symmetry than is required for the construction of the unit: it has *either* a plane of symmetry, *or* a digonal axis, *or* a centre of symmetry and no more. Mr. Shearer, who has been investigating these questions, concludes that we can lay down, at least provisionally, the two following principles:—

(1) Any symmetry in the molecule itself is reproduced in the crystal.

(2) The number of molecules in the elementary lattice is always the minimum number necessary to give the full symmetry to the crystal.

It follows that the symmetry of the crystal can never be less and will in general be greater than the symmetry of the molecule.

The replacement of a hydrogen atom by a hydroxyl-group destroys all the symmetry of the naphthalene molecule: because the X-ray analysis shows that it takes four molecules to make the crystal unit of either α- or β-naphthol. On the other hand, acenaphthene has as much, though conceivably not the same, symmetry as naphthalene. There are four molecules in the unit cell which is rhombic bipyramidal or, in other words, which can be obtained from a totally unsymmetrical molecule by reflecting across all three of a set of rectangular co-ordinate planes, as represented by $[(x, y, z,)\ (x, y, -z,)\ x, -y, z,)\ (-x, y, z,)\ (x, -y, -z,)\ (-x, y, -z,)\ (-x, -y, z,)\ (-x, -y, -z,)]$, an eight-point system. The molecule of acenaphthene has, like that of naphthalene, a two-fold symmetry of some kind.

The crystal unit of benzene itself attains the same symmetry by the use of two molecules only: the molecule itself has a four-fold symmetry, it might be itself monoclinic prismatic in form, $[(x, y, z,)\ (x, -y, z,)\ (-x, y, -z,)\ (-x, -y, -z,)]$ or rhombic pyramidal $[(x, y, z)\ (x, y, -z,)\ (-x, y, z,)\ (-x, y, -z,)]$. It has, in the crystal, no trigonal or hexagonal symmetry as might be suggested by the usual graphic formula.

Quartz has a sixfold symmetry which can be represented in cylindrical co-ordinates by $[(r, \theta, z)\ (r, \theta+\pi/6, -z)\ (r, \theta+\pi/3, z,)\ (r, \theta+\pi/2\ -z,\ (r, \theta+2\pi/3, z,)\ (r, \theta+5\pi/6, -z,)]$. Three molecules make up the crystal unit: and it is the threefold repetition of the molecule about the axis which introduces the 3 as a factor. Each molecule itself has digonal symmetry and no more: this symmetry is necessarily found in the crystal and gives the three digonal axes.

All these considerations are based on the principles of symmetry, which concern themselves with the *angular* dimensions of the crystal unit. With the examination of the *linear* dimension we enter another field of inquiry. The main lines were laid down by my son, W. L. Bragg, in a Friday Evening Discourse at the Royal Institution and subsequently in the Philosophical Magazine (August, 1920). It appears that to every atom may be assigned one or more radii of combination: so that when two atoms are neighbours in the construction of the crystal unit the distance apart of the centres is given by the sum of the two appropriate radii. An atom may possess more than one radius, according to the nature of the combination: but the number of such radii is so limited that the conception is most useful. In the case of the alkali halides, for example, each atom can be given a definite radius of combination, with consistent results. But if the nature of the combination is varied, so may be the radius. A simple example is that of calcium in the metal and calcium in calcium fluoride: it is necessary to assign a larger value to the radius of combination of calcium in the former case than in the latter.

Even the rule that, if an atom is surrounded by a number of like neighbours, it must be at the same distance from all of them, is sufficient at times to assist in the solution of a crystal structure. For example, in the case of ice, it is certain, *a priori*, that either an oxygen atom is surrounded by eight hydrogen atoms at equal distances from it, and a hydrogen atom by four oxygen atoms, or there is a six-to-three arrangement, or a four-to-two: and it is quickly found that the last is the only solution possible. Consequently every oxygen atom is at the centre of gravity of its four oxygen neighbours, from each of which it is separated by a hydrogen atom. This defines the structure, except that there are two alternatives, corresponding to the two alternative forms of close packing, hexagonal and cubic. The former is usual in the case of ice, but apparently the latter has been observed.

Other properties of the crystal have also been examined: Born, Landé, and others have considered the elasticity of the crystal in reference to the unit, especially in the case of polar crystals, such as rock salt. Older measurements of the physical properties of crystals are applicable now that the structure of the unit can be examined: but the whole field is barely touched as yet. Backhurst, who has investigated the effect of temperature, up to 900° C., on the reflecting powers of crystals has obtained some very interesting results, incidentally, on their behaviour during expansion. A cubic crystal expands uniformly in all directions of course; but the examination of the expansion of the crystal unit in various directions must give important results. For example, Backhurst finds that the expansion of graphite along the axis is very great: whilst across the axis it is small, perhaps no more than in the case of diamond. In the sapphire the effect of temperature upon the intensities shows that the relative arrangement of the molecules changes: the two aluminium atoms keep apparently at the same distance, 2·7 A.U., from each other—they are in a sense in contact—whilst the other atoms move with respect to them. A very interesting line of research opens up in this way.

Very little, indeed, has been done with respect to optical properties. Astbury has been examining the structure of tartaric acid: he finds that there are two molecules in the unit cell, and as the latter possesses twofold symmetry only, the molecule has no symmetry at all, as might be expected.

When a model is constructed in accordance with the indications of the X-ray analysis, it shows two spirals in each molecule. One of them lies in the carbon atoms at the core of the molecule and might be expected to persist in solution. It implies an optical activity peculiar to the molecule. The other spiral lies in the hydroxyl groups: it is due to the crystalline structure, and would disappear in a dilute solution in which the molecules have become totally independent. Lowry has predicted the existence of two terms in the expression of the optical activity of tartaric acid; the X-ray analysis suggests their origin.

In this short account it has been possible to describe, no more than briefly, the beginnings of what we may hope will be a great development of scientific research.

THE CHEMIST'S PART IN THERAPEUTIC PROGRESS

SIR WILLIAM POPE

THE daily Press has lately given a good deal of attention to a new chemical material which is supposed to be an absolute specific in cases of sleeping sickness; this interest is well deserved, but it is not clear that sound views on the subject are being placed before the public. It appears that a substance described as "Baeyer 205" has been found more useful than any previously known as a cure for sleeping sickness (*cf. J.*, 1922, 218 R); as it is very probable that many substances can be made which will effect this cure, no reason exists for doubting the justice of the claim.

So much importance is attached to the question that it has been thought necessary to send a deputation of German experts to British Central Africa to test the efficacy of their product and to prove its value. It is probable, and indeed greatly to be hoped, that they will succeed. The composition and method of manufacture of the substance are, of course, kept secret so that Germany may be enabled to sell it, at a profit, to the British Government. We are further informed by *The Times* of August 25 that the Baeyer works has provided material for use in the Belgian Congo against malaria and the various coast fevers. We are also told that at the meeting of the "Association of Tropical Diseases," held at Hamburg, the statement was made that "Baeyer 205" is the key to tropical Africa, and consequently to all the colonies, and that the German Government must "be required to safeguard this discovery for Germany; its value is such that any privilege of a share in it granted to other nations must be made conditional upon the restoration to Germany of her colonial empire."

It may be stated at once that no vast effort on the part of any scientific genius is required to produce a cure for sleeping sickness, or, indeed, of malaria, coast diseases, leprosy and many other maladies which make colonisation difficult. During centuries past a certain number of diseases have led to such extreme suffering and have proved so resistant to treatment that exaggerated views have been formed concerning the difficulty of finding a radical cure or an infallible preventive. The more mysterious is a disease in its nature and in its mode of attack, and the more horrible it proves in its effects, the more prone is the mind, by a simple psychological process, to attach difficulty to the problem of finding a cure or a prophylactic. Not many years ago one of the foremost of English physiologists remarked to me that he conceived two eventualities which would justify him in committing suicide: if he were suffering from cancer or from syphilis. He may retain his opinion with regard to cancer, a disease which we do not yet understand, but he has certainly abandoned syphilis as a justification for desperation.

As a result of scientific work of the very highest order of excellence we now know the nature of syphilis; this disease is due to the presence of a minute organism, the *Spirochæta pallida*, in the blood stream, and kinematograph exhibitions have been given showing the organism at work. The nature of the disease once established no great scientific genius was required for the production of a cure; a comparatively simple routine method is available for discovering a cure for syphilis and for those many diseases of allied character—malaria, coast diseases, leprosy—which make colonisation difficult. This efficient method of attacking the problem has been applied by the Germans; it consists in studying the toxic effects of all likely chemical substances on the lower organisms which may cause disease by establishing themselves in the blood stream. Ehrlich found that substance numbered 606 is more toxic to the organism of syphilis than it is to its human host; substance 606 then at once took precedence of all other means of treatment and established itself as the first definite cure for syphilis. Similarly it was found that injections with trypan-blue cure piroplasmosis or red-water, which had long been recognised as the scourge of all the great cattle-raising areas of the world. In the same way, if Baeyer 205 destroys the trypanosome before it kills the patient it will cure sleeping sickness.

If we have any faith in the methods of science and repose any confidence in the direct and logical conclusions drawn from experimental results we must believe that each disease of this particular parasitic class—syphilis, malaria, sleeping sickness, leprosy, etc.—can be cured by one application of some one of the myriads of chemical substances which can now be made. This being the case it seems shameful that this country, with its great overseas responsibilities, should be content to allow Germany, with no colonies, to carry out the simple programme of investigation which leads to the discovery of infallible curative agents for tropical diseases which are otherwise fatal.

The National Medical Research Council is well organised for studying the properties of any particular drug which may be brought to its notice, but something more than a medical or pharmacological organisation is needed for the efficient working-out of the problems presented. The Government requires a council of chemists capable of drawing up a programme of work involving the preparation of series of allied compounds which may be expected to be toxic towards the lower organisms productive of this particular large class of diseases; with means of promptly making these compounds, and with the facilities already in existence for studying their therapeutic action, our country would quickly take precedence of Germany in the discovery of curative methods, and would make impossible the ridiculous claims recently put forward at the Hamburg meeting referred to above. The fact that an "Association of Tropical Medicine" exists in Germany, with the main objects of curing diseases which do not occur in German territory, and of drawing a commercial profit by treating those diseases in the territories of Britain and her Allies, is ample condemnation of our method of coping with tropical problems.

Clearly, what is required is the establishment of an advisory council of chemists to the Government to confer, to draw up a programme, and to see that it is carried out; the supply of the necessary research materials to the National Medical Research Council would thus be assured. As has often been pointed out before, such an advisory council would render inestimable service in connexion with the applications of chemical science and technology to many branches of national activity.

MEETINGS OF OTHER SOCIETIES

INSTITUTION OF RUBBER INDUSTRY

At the meeting held in the Engineers' Club, London, on September 4, Mr. F. Kaye read a paper on "Rubber Latex in Paper-Making."

Rubber latex is a limpid liquid which contains 30 to 35 per cent. of rubber and is miscible with water in all proportions. Ammonia is an efficient preservative, the cost being from 1½d. to 2d. per gallon of latex, and material thus preserved is selling in London at 4s. 3d. per gallon. The cost of breaking down the coagulated rubber used for compounding may be from £7 to £8 per ton, and this can be set against the increased freightage on rubber imported in the form of latex.

The method of using rubber latex in paper-making is comparatively simple, the essential condition being extensive dilution of the latex before addition to the beaten pulp, so that the latex quickly penetrates and becomes intimately associated with every particle of the beaten fibre. After thorough mixing with the pulp the rubber is thrown out on the fibre by suitable coagulative agents, such as magnesium sulphate or acetic acid. Alum is found, however, in most cases to be effective, used exactly as in ordinary paper-making processes. If the paper has to be tub-sized alum can be used as the coagulative agent, and if the paper is machine-sized the latex may be added before or after the size and alum, provided that sufficient alum is added to throw out the size and rubber completely.

Rubber latex has some specific effect upon the fibres in the beating engine and upon the rate of hydration of the fibres. Fibres in paper made with small or large amounts of rubber latex are often closer and more uniform in texture than a paper made of the same fibre without rubber latex. Paper can be considerably improved by adding such small amounts of latex as will give a rubber content of 0·1, 0·2, and 0·5 per cent., and vegetable, animal, and even mineral fibres, such as asbestos, may be used in paper containing rubber latex. New qualities of paper can be made, and if larger proportions of rubber are introduced it will be quite possible to make leather substitutes and linoleum substitutes on a paper-making machine. Experiments show that all kinds of stock—paper, boards, leather and linoleum substitutes—can be dyed during the process of manufacture in the beating engine, as rubber in the latex form takes up the dye quite as freely as the fibre, so that a great variety of effects can be produced.

INSTITUTION OF CHEMICAL ENGINEERS

At the twelfth meeting of the Provisional Committee, held on August 2, Sir Arthur Duckham presiding, it was reported by the solicitor that the registration of the Institution by the Board of Trade was still delayed.

The suggestions of the Institute of Chemistry were agreed to, viz., that the definition of Chemical Engineering should be omitted, and that a clause should be inserted stating that the Institution claims no right to prescribe courses of study or to hold examinations whereby qualifications, or authority to practice or to use any distinctive title, can or may be conferred in respect of the practice as such of analytical or technical chemists (other than chemical engineers) or of teachers of chemistry.

The Committee was unanimously opposed to changing the title of the Institution.

A balance-sheet and revenue account were submitted by the hon. treasurer, showing a surplus balance of £225 6s. 8d.

The hon. secretary reported that over 100 completed application forms for membership had already been received. It was agreed that the question of membership must be held in abeyance until negotiations with the Board of Trade were completed, which it was hoped would be in about six weeks' time.

CORRESPONDENCE

PASTEUR COMMEMORATION FUND

Sir,—I have to inform you that a sum of £848 14s. 6d. has been subscribed to the above fund, and you will find appended a list of the subscribers. This amount is in addition to sums which had previously been sent to France in response to earlier and direct appeals.

In accordance with a resolution passed at a recent meeting of the Pasteur Commemoration Committee, presided over by Sir Charles Sherrington, a draft for the above amount is being forwarded to Monsieur Héring, the General Treasurer, with an intimation that should the amount prove more than the French Committee desires to expend upon the monument, the excess should be devoted to some other form of permanent memorial of Pasteur in the University of Strasbourg.

On behalf of the Committee, I desire to take this opportunity of thanking you for your assistance.—I am, Sir, etc.,

A. Chaston Chapman,
Treasurer and Secretary.

SCIENTIFIC INSTRUMENTS: THEIR CONSTRUCTION AND APPLICATION

Sir,—Science, in the minds of many, is a side issue in the business of life—something that real, live industry can very well get along without. To such the mention of a scientific instrument merely draws attention to something considered unessential to material prosperity and national expansion. For this reason I am sorry that the Institute of Physics has chosen such a title as "Journal of Scientific Instruments" for its proposed publication. I do not dispute the fact that its mission is to describe instruments that have been developed by scientific research and perfected by an appreciation of the value of scientific precision; but I believe that, although the publication of details will help science to make fresh discoveries, the main object of the new publication should be educative—so that the scope and uses of such instruments can be appreciated by industry.

It is mentioned, tentatively, in the prospectus that Dr. Leonard Hill is to describe the katathermometer in a forthcoming issue. Although its invention was a scientific achievement, I am interested in it chiefly because of its application as a valuable guide to atmospheric conditions underground. Another interesting instrument is an electrical CO_2-recorder, which dispenses with chemicals—an additional example of scientific research of considerable value to economical power-plant operation.

The new journal, I feel sure, will do better commercially if it conveys by its title some idea of the immense service it can be to industry.

A. W. ALLEN.

Berkeley, Cal.
July 11, 1922.

NEWS AND NOTES

FRANCE

Alcohol as Motor Fuel

The following is a summary of an article contributed to *La Dépêche* by Monsieur E. Barthe, president of the Wine Industry Association (Groupe Viticole), and also of the "Carburant National," a committee appointed by the Government to investigate the use of alcohol either in place of or admixed with petrol.

In France it is permitted to incorporate 10—15 per cent. of alcohol with petrol, and chemists have recently been concentrating their attention on such mixtures without, however, losing sight of the possibility of gradually increasing the production of alcohol so that it may eventually replace petrol to a very much larger extent. On mixing 90 parts by volume of petrol and 10 parts of industrial alcohol (95—96 vol. per cent.), the liquid invariably separates into two layers, owing to the 4—5 per cent. of water originally present in the alcohol; but if the alcohol be absolute, or nearly absolute (99·5 vol. per cent.) such separation does not occur. The problem therefore was to manufacture alcohol of this strength on an industrial scale. M. Lorette, an engineer, has succeeded in making it at a cost very little exceeding that of industrial alcohol by the simple process of dehydrating the *vapour* of aqueous alcohol with quicklime, instead of the liquid, as hitherto. No essential alteration of the distillation apparatus is necessary; it suffices to interpose a column containing lime between the plate distilling-column and the condenser. In this way alcohol of 99·8 per cent. by volume is obtained in a single distillation. Trials have been made on a large scale at the arsenal of Sevran with improvised columns working intermittently, and 5000 litres of absolute alcohol has been produced with the consumption of about 21 kg. of quicklime, which is readily saleable after use. It has been proved that mixtures of the alcohol with petrol remain homogeneous at a very low temperature (—25° C.), and that the stability of the mixture is not affected by exposure to moisture. Motor trials made with the mixture at Sevran, and by the Autobus Cie., have given very satisfactory results.

It will now be possible to make compulsory the addition of a proportion of alcohol to all imported petrol. During a debate in the Parliamentary Commercial Committee, it was objected that since notable quantities of petrol are used for lighting purposes, it would be difficult to make compulsory the admixture of alcohol and lamp petrol; but M. Patart has shown conclusively that these two liquids mix in all proportions and that the mixtures burn well in stoves, lamps, etc. Thanks to the discovery described above, it is probable that the proposal of compulsory admixture of alcohol with petrol made by the Groupe Viticole will be approved and adopted.

UNITED STATES

Government Assistance to the Chemical Industry

The Chemical Division of the Bureau of Foreign and Domestic Commerce, organised by Secretary Hoover, came into being on August 1. Its object is to place at the disposal of American chemical manufacturers accurate and detailed information concerning foreign markets for their products. The Division is sub-divided into the following sections:—Chemicals, general organic and inorganic; dyes and coal-tar chemicals; pigments, paints and varnishes; fertilisers and fertiliser materials; botanical drugs, pharmaceutical and medicinal preparations; essential oils, perfumery, cosmetics, and toilet preparations; explosives and fireworks.

One of the first tasks will be to compile a list, to be called the Exporters' Index, of American firms interested in the development of foreign trade, which will serve as the basis for distributing information on trade opportunities and conditions in foreign markets. Another will be the appointment of advisory committees to promote co-operation among the several branches of the industry, including existing trade associations, and the Department of Commerce; and an important feature of the work will be the periodical publication of analyses of export and import statistics relating to chemical commodities.—(*U.S. Com. Rep., Aug.* 14, 1922.)

CANADA

Industrial Notes

The Winchester Dye Co., Ltd., has been incorporated and is equipping a plant at Trenton, Ont. It expects to place colours on the market at an early date.

The Dominion Dyestuffs, Ltd., has erected a plant at Fergus, Ont., for the production of a line of ten or twelve standard colours including acid, direct and chrome dyes.

The Rocky Mountain Paint Co., Calgary, Alberta, will start the manufacture of paints and colours at an early date. The company controls vast deposits of mineral colour-bearing materials in the western area of the province.

The Firestone Tire and Rubber Co., Akron, Ohio, will soon commence the construction of a new plant at Hamilton, Ont., to be equipped for an initial capacity of 3500 tyres a day. It is proposed to have the factory ready for operation before the end of the year.

Two new paper and pulp companies have been incorporated in British Columbia: the Wigwam Pulp and Paper Co., Ltd., with a capital of $5,000,000, and the Bloedel, Stewart and Welch Corporation, with a capital of $1,000,000. Both companies will operate in the Province.

Operations will be commenced this season in the construction of the plant of the Peninsula Sugar Co., Ltd., at Petrolea, Ont. The refinery will have a capacity of 600 tons of beets a day. Lambton County is one of the best sugar-beet growing areas of the Province, and thus the new refinery will be situated in the centre of its raw material. The machinery will be electrically driven and of special design. The plant will cost nearly one million dollars.

Forests and Forest Products

The area of the Province of Quebec is now 450,337,761 acres or 703,653 sq. miles. The Crown controls 434,724,394 acres of which 44,500,000 acres are under licence for the cutting of timber. The total acreage in the Province capable of producing saw logs, pulpwood, etc. is 130,000,000, divided into the following five classes according to their tenure: (*a*) private forests, 6,000,000; (*b*) forests on lots under location ticket, 1,300,000; (*c*) forests leased or timber limits, 44,500,000; (*d*) township forest reserves, 200,000; (*e*) vacant lands, 78,000,000 acres.

The estimated wealth of the forests in terms of timber is as follows:—

Species.	Volume. Billion feet board measure.
White and red pine	30
Spruce, fir, hemlock and resinous trees, except cedar	125
Cedar (arbor vitæ)	20
Pulp wood	100
Hard woods (deciduous trees)	35
Total	310

From 1867 to 1920 the forests, under licence, have yielded to the Provincial Treasury $48,148,220.

Railway sleepers of creosoted fir from British Columbia have been tried upon the Indian railways and found to withstand attacks of fungi and ants. Last year over 8 million feet and this year, to date, over 7 million feet have been forwarded to India.

Mining and Metallurgy

The value of the mineral production of the Province of Quebec for 1921 amounted to $15,522,988, as compared with $28,392,939 in 1920. The past year shows a decline in value of $12,869,951, or 45·3 per cent. The metallic products reached a total value of less than $100,000, whereas in 1920 they represented $483,888. In 1919 the value was $1,014,088, and $2,855,120 in 1918.

It is reported that an extensive deposit of iron ore, running 60 per cent. iron, has been discovered north of Hudson's Hope, near the boundary of Alberta, in British Columbia, west of Peace River. This district produces considerable amounts of high-grade coking coal.

A geological survey is being made this summer of the iron-ore deposits of British Columbia, special attention being given to the haematite ores of the Kootenays and the magnetite deposits of the coast. Analyses of the iron ores from the north shore of Lake Athabasca, near Crackingstone Point, show iron 49·5, sulphur 0·08, phosphorus 0·03, and silica 21 per cent. The Consolidated Mining and Smelting Co. has developed an electrolytic process for the production of pure iron from the pyrrhotite gangue of the Sullivan Mine.

Ten tons of iron ore from Sarita River district, Vancouver Island, have been tested and reported to be satisfactory.

A meeting was recently held in Toronto at which a number of metallurgists interested in iron production were present. The matters considered were chiefly plans for the encouragement and development of the iron-ore industry in Ontario, and particularly regarding the possibility of working out methods by which low-grade ores can be treated economically. Suggestions were made which are having the attention of the Ontario Government.

GERMANY

Society for Colloid Chemistry

A new society, to be called the "Kolloidchemische Gesellschaft" and to be devoted to pure and applied colloid chemistry, is to be inaugurated on September 15 at a special meeting in Leipzig. A large number of distinguished scientists and many industrial firms have agreed to become members, and at the meeting in question, following the transaction of business matters, some eighteen chemists and physicists will speak on the relations of colloid chemistry to other sciences and to industry. The programme, in fact, is so full that each speaker will be restricted to a maximum time-limit, which will be recorded by a special automatic (acoustical) time-keeper. A kinematograph film depicting "Snapshots of Colloidal Solutions" will be shown and explained by Prof. Siedentopf of Jena. Prof. Wo. Ostwald is acting as secretary *pro tem.*

Metallurgical Research

The economy of material necessitated by the sharp competition which has existed among makers of machinery during the last ten years, has led to the erection, both by large and small firms, of laboratories in which practically every property of a metal or alloy is tested prior to use, and which have become indispensable adjuncts to the works. Much of this work was promoted by the late Prof. Emil Heyn, who actively investigated the strength and behaviour of materials under various conditions. In these laboratories a great deal has been done to improve the technically valuable properties of those metals which are produced in Germany, and many new alloys have been prepared. Of late, non-ferrous metals have received most attention, and in particular such light alloys as "elektron," "duralumin," and "silumin," whose properties have been improved, and whose use is increasing.

Capital Increases in the German Chemical Industry

Already in 1920 the average share capital of German chemical companies had increased fourfold, and now the increase is about tenfold. Particularly noteworthy is the increased capitalisation of the companies forming the "Interessengemeinschaft," whose stock has only been "watered" to a small extent, much new capital having been invested in plant extensions. The falling off in the average dividend disbursements since the Peace is not only connected with increased capitalisation, but also with the high level of profits which was achieved before the war. The reports of the companies show that their position is not wholly indicated by the dividends. Especially is this seen when market quotations are examined with reference to concessions to shareholders. Where the dividends show most marked disproportion to the quotation, an explanation is found in some expectation of preferential treatment.

Efficiency of Labour in German Factories

From observations made at the Höchst Farbwerke the following table has been compiled showing the time taken to execute various industrial operations during recent years, the time required prior to 1914 being taken as 100:—

	1919	1920	1921	Jan.-Feb. 1922
Coopery and joinery	94	95	102	120
Turning	51	86	107	110
Forging	86	106·5	110·5	—
Filling containers with dyestuffs	—	—	85·8	93·7
Loading coal by hand	—	—	71·5	62·8
Loading coal by steam crane	70	79	79	91·7

The results of the investigation show the great influence exerted by the change from hourly to piece rates.

The Cellulose and Paper Industry

The cellulose and paper industry, which before the war made few profits, is stated to have mproved its position during recent years. The verage dividend has increased from 7·7 per cent. efore the war to 21·6 per cent. in 1921, whilst the verage capital in 1920-21 was less than double that n 1913-14. Each of the ten chief companies (upon he results of which the present figures are based) urther increased its capital in 1921. The average hare quotation has increased 31·2 per cent. above hat of June 5, 1920, and 83·3 per cent. above the ominal value. The average amount written off ncreased from 0·61 million marks in 1913-14 to 4·42 ill. mk. in 1920-21. It is well-known that profits n this industry have been derived almost entirely rom the home trade.

uel Production

The Government Statistical Bureau (Statistisches eichsamt) gives the following figures of production for the year 1921 and the first six months of 922 (exclusive of the Saar district):—

	1921	1922 Jan.–June
	Millions of metric tons	
Coal	136·21	66·647
Brown coal	122·99	65·938
Coke	27·92	14·366
Coal briquettes	5·689	2·567
Brown-coal briquettes	28·24	14·107

There was a considerable decline in production uring June, 1922.

oal Research

The Kaiser Wilhelm Institute for Coal Research ompleted its eighth year at the end of July. The ork, both scientific and technical, done at the nstitute is recorded in the five published volumes f the "Abhandlungen zur Kenntnis der Kohle," nd in a sixth volume now in the press. On the cientific side the Institute has investigated the rigin and chemical constitution of coal, and the ode of formation of the products of distillation. he chief result of the investigations is that, in he main, coal is not formed from vegetable cellulose ut from lignin through humic acid, the cellulose enerally disappearing through fermentation during the process of decay. The technical work has ncluded the production of oils by low-temperature istillation of the fuel in a rotary furnace. Oils roduced from coal, lignite and peat contain nearly ll the substances occurring in mineral oils, such as enzine, lubricating and fuel oils. The tar contains p to 50 per cent. of higher phenols for which no use as yet been found, but last year a simple method of separating them was discovered, viz., by distillation in superheated water at 225° C., the less soluble phenols separating out on cooling. It was also found that these phenols are converted almost quantitatively into a mixture of benzene and toluene by passing them with hydrogen through a tinned iron tube at 750° C.

Lime in German Chemical Industry, 1919—21

Since its enforced restriction during the war the production of lime and related products has increased very largely. The combined production of the firms constituting the "Deutscher Kalk-Bund" was as follows in 1920 and 1921:—

	1920	1921
	Metric tons.	
Quicklime	3,052,968	4,048,034
Calcined dolomite	144,264	142,681
Marl	623,750	693,780
Ground lime (crude)	134,434	115,578

The output of quicklime in 1921 was more than double that in 1919 (2,003,565 t.), but was much below the average pre-war figure of 6·5 million tons.

In the period 1919-21 the quantities of lime used by the chemical industries were 177,006 t. (9·0% of total) in 1919, 257,267 t. (8·5%) in 1920, and 258,555 t. (6·4%) in 1921. In the sugar industry the amounts consumed were 6066 t. (0·3% of total) in 1919, 8220 t. (0·3%) in 1920, and 8545 t. (0·2%) in 1921. After the building industry, the iron and steel industry is the largest user of lime. In 1919 it consumed 578,120 t. (29·3%), in 1920 676,859 t. (22·5%), and in 1921 876,815 t. (21·8%).

GENERAL

Vanadium Compounds in Medicine

Falling in the same group of the Periodic Law as arsenic, antimony and bismuth, it is not surprising that vanadium has frequently been tried in some form or other in medicine. The simple vanadates have been applied in anæmia, tuberculous infections and other chronic diseases with little or no success. Vanadic acid has, however, been recognised as an efficient antiseptic in skin affections. Compounds of vanadium, with vanadium directly linked to carbon, analogous to the valuable arsenic compounds, are unknown, but compounds in which vanadium is linked to carbon *via* oxygen atoms have recently acquired some prominence. In 1917 Pröscher, Seil and Stillians demonstrated the antisyphilitic action of vanadium on the rabbit and in man, and the experiments have borne further fruit in the hands of the French observers, Fournier, Levaditi and Schwartz. These workers, following up the beneficial effects observed by themselves in the treatment of syphillis in man with complex bismutho-tartrates, have now tried various compounds of vanadium, niobium and tantalum with successful results only in the case of vanadium. The complex tartaro-vanadates of sodium or potassium, when injected intravenously or subcutaneously into syphilitic rabbits, have effected permanent cures, and in man the results were sufficiently encouraging to justify further search for somewhat less toxic combinations.

Vanadylformates, salicylates and tartrates were described some years ago by Barbieri, and coordination compounds of vanadium and acetylacetone and benzoylacetone by Morgan and Ross, but their therapeutic action has not yet been recorded.

The Swiss Aluminium Industry

Before and even during the war the policy of the Swiss aluminium industry was to supply the German aluminium-working industries with raw aluminium, but the depreciation of the mark and the increase in home production during the war reduced exports to Germany from 5644·7 metric tons of aluminium in 1913 to 3542·4 t. in 1920 and 1646·1 t. in 1921. This compelled the Swiss aluminium industry to look for new markets, which were found in the United States and Japan. Thus in 1921, 3420·6 t. of aluminium to the value of 8,523,000 fr., found its way to the United States, and 894·1 t. valued at 2,075,000 fr. to Japan. Besides this, Switzerland's aluminium industry, which is concentrated in the hands of the Aluminium Industry Society, of Neuhausen (capital 42,000,000 fr.), has commenced to pay more attention to the home aluminium-working industries and to participate financially in these. During 1921 the Swiss aluminium rolling mills exported 1193·4 t. (valued at 5,402,000 fr.), half of which went to the United States, and one quarter to British India. There are also several factories of aluminium vessels and other goods, the export figures of which totalled nearly 5,000,000 fr. in 1921.

Output of Minerals and Metals in Italy, 1921

According to figures prepared by the Central Inspectorate of Mines, the output of minerals and metals in Italy in 1921 was as follows:—

	Metric tons 1921 Estimated output	1920 Actual output
Minerals:—		
Iron ore	274,000	389,876
Manganese-iron ore	6,980	90
Manganese ore	4.700	36,158
Copper ore	22,700	14,450
Argentiferous copper	—	1,759
Lead, silver-lead and silver ore	26,509	40,729
Zinc ore	69,000	95,985
Lead-zinc ore	340	570
Lead-zinc-copper ore	500	1,043
Pyrites	448,600	321,589
Anthracite	21,000	28,402
Coal	90,400	123,460
Lignite	1,019,700	1,571,735
Bituminous schists	3,150	16,325
Peat	63,500	147,607
Mercury, metallic	1,070	1,401
Sulphur	313,400	296,099
Salt, rock	45,400	46,989
Salt, brine	45,300	22,026
Petroleum	4,780	4,937
Asphaltic and bituminous rock	91,800	106,642
Bitumen, crude	600	984
Ichthyol shale	1,100	800
Alunite	1,170	3,445
Bauxite	49,100	13,139
Leucite	9,900	8,200
Magnesium sulphate	350	1,200
Boric acid	2,490	1,719
Graphite	5,750	5,398
Marble	254,000	352,421
Calcium carbonate, powdered	6,500	8,500
Pumice	10,900	25,200
Talc and steatite	21,000	21,475
Barytes	13,500	15,380
Mineral colours	10,900	11,838
Quartz	31,000	63,480
Felspar	2,400	2,600
Kaolin	13,600	19,323
Magnesian earths	9,400	33,850
Refractory materials	42,000	54,627
Metals, etc.:—		
Iron	60,400	88,072
Steel	683,200	773,761
Alloys	15.400	20,881
Copper	100	685
Lead	11,500	15,947
Zinc	380	1,177
Antimony	40	160
Aluminium	740	1,238
Zinc white	280	1,308
Coke, metallurgical	50.000	95.727

(*G. Chim. Ind. ed App., May*, 1922.)

Mineral Production of Mexico in 1921

Statistics published by the Department of Mines give the mineral production of Mexico in 1921 as follows:—

	Fine oz.
Gold	684,673·0
Silver	64,468,064·41
	Metric tons
Lead	60,318·3
Copper	15,228·1
Zinc	1,256·9
Mercury	46·2
Molybdenum	3·2
Graphite	2,911·1
Arsenic	785
Tin	0·5
Antimony	44·5
Tungsten	14·3
Manganese	558·8

—(*U.S. Com. Rep., June* 26, 1922.)

Vegetable-Oil Industry in Brazil

Mr. J. B. de M. Carvalho [a member of this Society] has recently been visiting the oil-mills in Northern Brazil on behalf of the Brazilian Government. In his report to the Minister of Agriculture, Mr. Carvalho recommends the establishment of an experimental station at Para, to serve the States of Amazonas, Maranhao and Piauhy, and another in Bahia. In all these States vegetable-oil seeds are abundant. He recommends, further, that particular attention be given to the hard-shelled babassu nut, which grows so plentifully, particularly in Maranhao and Piauhy, and which he thinks can now be crushed by a recently-invented crusher; and that experiments be conducted on the oiticica nut, which contains an excellent drying oil, and on the batiputa, which yields an edible oil. Mr. Carvalho is now making a survey of the vegetable-oil resources of the Southern States of Brazil.—(*Cotton Oil Press*, 5, 11, 1922.)

Nauli "Gum," a New Oleo-Resin

A sample of this "gum," yielded by a large tree that grows plentifully in the Solomon Islands, was examined at the Imperial Institute and found to consist of pale yellow, sticky lumps of a fairly soft oleo-resin with a strong odour of aniseed. Its percentage composition was: moisture 2·5; volatile oil 10·4; resin 8·18; matter soluble in water (largely anisic acid; no gummy matter was present) 3·7; matter insoluble in alcohol (mineral and vegetable impurities) 1·6 per cent. The "gum" is thus an oleo-resin that yields about 10 per cent. of a pale-yellow volatile oil which is quite unlike commercial turpentine oils, and apparently contains a relatively small quantity of terpenes and about 34 per cent. of anethole. Although the oil would be valueless as a turpentine substitute, it might be utilised as a source of anethole or as a substitute for anise oil. It only possesses about half the flavouring power of star anise oil, and would therefore not realise more than half its price. After removing the volatile oil, the residual resin was found to resemble gum dammar in certain respects, and to be suitable for making varnishes for mixing with colours immiscible with ordinary varnish. Being insoluble in caustic alkali, the resin could not be used in soap or size manufacture; it would probably sell at the same price as ordinary rosin of the same colour. It is suggested that the best method of exploiting Nauli "gum" would be to distil it locally or in Australia, and to market the oil and resin separately.—(*Bull. Imp. Inst.*, XIX, 4, 1921.)

PERSONALIA

Assistant-Professor K. N. Moss has been appointed to the chair of coal and metal mining in the University of Birmingham.

Prof. Lindet has been elected president of the Association des Chimistes de Sucrerie et de Distillerie de France et des Colonies.

Mr. Ernest A. Smith has resigned the secretaryship of the British Non-Ferrous Metals Research Association and accepted the appointment of research metallurgist to the Sheffield Smelting Co., Ltd.

The Salters' Institute of Industrial Chemistry has awarded fellowships for post-graduate study to Messrs. O. G. Harris, W. S. Martin, J. H. Oliver and W. Randerson, and has renewed the fellowship of Mr. F. Raymond Jones.

Dr. W. H. Nichols is to represent the chemical industry of the United States on a joint committee of the Society for the Promotion of Engineering Education and of the National Industrial Conference Board, which has been appointed to consider the problem of training in engineering.

The following appointments are announced from Germany:—Prof. R. O. Neumann has become director of the Institute of Hygiene of Hamburg University in succession to the late Prof. W. Dunbar; Dr. H. Lecher has succeeded Prof. Freudenberg in the chair of organic chemistry at Freiburg University; and Prof. Wilke has accepted he chair of technical organic chemistry in the Stuttgart Technical *Hochschule* vacated by Prof. Gutbier.

* * *

Prof. A. Smith, head of the chemistry department of Columbia University, has died in Edinburgh.

The death is reported of Armand Vivien, the author of numerous papers on problems of the sugar industry.

We record with regret the death, at Meran, of Prof. E. Noelting, a well-known worker in the sphere of dyestuff chemistry, and formerly director of the school of chemistry in Mülhausen.

The memorial tablet to the late Sir William Ramsay will be unveiled in Westminster Abbey on Friday, November 3, at noon, by H.R.H. the Prince of Wales, who is patron of the Ramsay Memorial Fund.

From Austria the deaths are announced of Dr. F. Kretschmer-Forstburg, formerly professor of chemistry in the University of Vienna, aged 80 years; and of Dr. Th. Panzer, professor of physiological chemistry in the veterinary *Hochschule* of Vienna, aged 50 years.

The following deaths are announced from Germany:—Dr. H. Rubens, director of the Physical Institute of Berlin; Prof. E. Bergmann, director of the Chemisch-Technische Reichsanstalt of Berlin; R. G. A. Loibl, technical director of the Ratibor sugar factory.

Corrigendum.—In the issue for July 31, p. 312 R, ol. i, three lines from the bottom, for "16 ounces f platinum metals" read "0·16 oz. of the platinum roup of metals."

REPORTS

British Empire Patent Conference, 1922. *Report of the Conference held at the Patent Office, London, June, 1922. Pp.* 28. *H.M. Stationery Office*, 1922. *Price* 1*s.*

A committee of the recent Conference of Prime Ministers and Representatives of the United Kingdom, Dominions and India recommended that a conference of representatives of the Patent Offices of His Majesty's Dominions should be held in London to consider the practicability of instituting a system of granting patents which should be valid throughout the British Empire. This Report is the result of the recommendation.

The United Kingdom, Canada, Australia, New Zealand, South Africa and India were represented at the Conference and there was also present one representative for the several Colonies and Protectorates. No evidence was taken.

At least 46 separate applications for protection are at present necessary for obtaining monopoly throughout the Empire, at a cost of about £300. If patents or their equivalents are granted, they are taxed to an extent amounting, for the whole Empire, to about £1200 during their life.

This was considered unsatisfactory by the Conference and it was resolved that a British Empire patent would be desirable as a means of cheapening the cost and simplifying procedure, provided that the autonomy of the Dominions and India were preserved.

Of the schemes considered for putting the resolution into effect, that involving abolition of local Patent Offices and the establishment of an Imperial Patent Office was rejected owing to practical difficulties and the necessity for preserving the right of the inventor to obtain a local patent. Another scheme by which the same search into novelty should be made by each local Patent Office and the locally granted patent should be operative throughout the Empire, was also rejected as too costly. Nor was the proposal acceptable that searching should be conducted solely by the United Kingdom.

The scheme preferred provides for retention of the local Patent Offices and their systems of granting local patents, and the establishment of a Central Patent Office for examining applications and granting patents, which may extend to as many territories as the applicant may desire, the application being open to opposition. The search to be co-extensive with that made at present in the United Kingdom, the Dominions and India. The main advantage of the scheme would be that the applicant would have to make only one application.
